# ARTHRITIS DEFORMANS.[*]

## THE REPORT OF A SERIES OF ONE HUNDRED AND TEN CASES FROM THE JOHNS HOPKINS HOSPITAL.

(FROM THE CLINIC OF PROFESSOR OSLER.)

THOMAS McCRAE, M.D., M.R.C.P. (Lond.)
THE JOHNS HOPKINS HOSPITAL
BALTIMORE.

There is no intention in this paper to make any attempt to discuss the many debatable points relative to arthritis deformans. There is, perhaps, no common disease in the calendar about which we have as little exact knowledge. Much misapprehension has been caused by the use of names which suggest that this disease has some association with rheumatism. Beginning with the very name to be given to it, we have great diversity of opinion, which continues through the etiology and pathology of the disease. Dr. Bradford[1] has recently described well the chaotic condition of our knowledge, or rather lack of it, and laid emphasis on the necessity of more careful study of the disease. We are to-day really proving the truth of words spoken by Haygarth in 1805, who said: "The term rheumatism has been applied without sufficient discrimination to a great variety of disorders, which, except pain, have but few symptoms that connect them together."

In the present paper a series of 110 cases which have occurred in the Johns Hopkins Hospital are reported. The clinical features will be especially discussed. A point of much importance is the relative frequency of the disease. With the present confusion of our knowledge of the disease, any statistical figures seem to possess but little value. As some of the cases here reported suggest strongly that one type of the disease is very commonly taken for acute articular rheumatism, and as probably one other form of the disease—spondylitis—has usually been overlooked, statistics are only likely to lead to false conclusions. It probably occurs less frequently than true articular rheumatism, but the difference in number may not be as great as we have usually thought.

One point to which special attention will be drawn is the study of early diagnosis. How much we can do to prevent the later manifestations of the disease by recognition and treatment of the early conditions is difficult to say. Certainly we are in a position to try, whereas by making a diagnosis only when the damage is done, treatment then can only be palliative.

### PATHOLOGY.

Of this we have but little accurate knowledge. With the etiologic feature unknown we can only discuss the morbid anatomy and not the pathologic basis. In the usual descriptions of the disease we have given only the later changes, many of which are degenerative. That the early acute conditions have received little attention is natural, for the material has been lacking. Patients rarely die of the disease, and certainly not in the early stages. Dr. White[2] has recently reported the result of an autopsy on a comparatively early case. It is to be hoped that no like opportunity for examination of such a case will be missed.

The two great views of the etiology—namely, the infective (either due to a specific organism or to a variety of organisms) and the neural—need not be discussed. The clinical features of this series seem rather to point toward an infective cause, although our cultural results have been negative.

Some writers suggest that under the term arthritis deformans we have really two diseases. Whether or not this be correct, we can distinguish two types of cases, one in which the bony changes, especially hypertrophy, predominate, often termed the "osteoarthritic," and the other in which the joint structures other than the bony parts are especially involved, sometimes termed "rheumatoid." These are usually distinctly different conditions. Do they represent different diseases, or are they varying manifestations of the same disease? The answer is difficult at present, but there seems little doubt of the co-existence of lesions of both types in some patients. Thus, in patients with spondylitis usually regarded as being "osteoarthritic" we may find involvement of other joints with the condition regarded as "rheumatoid."[3] Whether the same etiologic factor is active in both, it is at present impossible to say.

Some reference should be made to the association of arthritis deformans and rheumatism. Some writers describe arthritis deformans as coming on after acute rheumatism. The two diseases may have occurred in the same patient, but it is not any more likely than that rheumatism and gout should have done so. If we see a patient in successive attacks of acute polyarthritis which we regard as acute rheumatism, until he comes back, perhaps, with a tophus, do we say that gout has followed acute rheumatism? If we are honest, we frankly admit our error in mistaking the nature of the arthritis. Why not the same in regard to arthritis deformans? When a patient comes with undoubted manifestations of this disease it seems more reasonable to consider previous acute attacks to have been of the same nature. The two diseases may have occurred in the same patient, but it seems more probable that the acute attacks were of arthritis deformans than acute rheumatism. The large number of cases to be noted later support this view. It seems most reasonable to hold that arthritis deformans is distinct from acute rheumatism.

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

[1] American Medicine. 1902, iv, 17.

[2] Guy's Hospital Reports, lvii.

[3] The use of the term "rheumatoid" is to be regretted. Everything suggesting any association with rheumatism should, in my opinion, be eliminated. I have used the term "polyarticular" to designate the group in which these lesions especially occur.

For clinical study it is necessary to divide the cases, and in this report the following classes are used:

1. Heberden's nodes.
2. Polyarticular form (excluding the spondylitis cases, which are in one sense polyarticular).
3. Monarticular form.
4. Spondylitis.

It must be understood that the lines between these are not always definite. A patient with spondylitis or Heberden's nodes may have general polyarticular involvement, although this mixing of the types is not very common.

The statistics for the whole series will first be given, and afterward each group will be discussed in detail. That the present series gives any guide to the relative frequency of various groups is not probable. This is especially to be kept in mind in reference to the cases with local involvement of the spine. The cases of general spinal involvement offer but little difficulty in recognition, but we have only recently learned to recognize the other cases, and therefore their absence in the records of previous years has been due to non-recognition. These cases occur especially in males, and doubtless future records will show a more equal distribution between the sexes than previous ones have done. It will be seen that in this series the males and females are equal, rather unusual in any large series.

It may be noted that no cases with Heberden's nodes only are included in this series. Two cases of the so-called "Still's disease" are included in the polyarticular group. These cases are somewhat doubtful, but it seems most reasonable to consider them as arthritis deformans.

### GENERAL STATISTICS.

*Incidence.*—In the present series of 110 cases, 55 were males and 55 females. The white patients numbered 106, the colored only 4, 2 of whom were males and 2 females. The small number of colored patients with the disease is of considerable interest, especially in reference to the association of previous septic conditions as etiologic factors. The colored race is susceptible to the majority of infections, and especially gonorrhea. While in the hospital the proportion of white to colored is as about 7 to 1, the incidence of arthritis deformans is about 26 to 1. The negro is also apparently rather more prone to acute articular rheumatism, as has been elsewhere brought out,[4] the proportion in this clinic of white and colored with this disease being as 4.8 to 1.

*Conjugal Condition.*—Fifty-three of the patients were married, 41 single, and 16 were widows or widowers.

*Nationality.*—It is interesting to note the preponderance of the native-born. Ninety-six were born on this continent, and only 14 abroad. Of these, 8 were German, 2 Irish, 1 each English, Bohemian, Russian and Pole.

*Occupation.*—The largest number were engaged in housework of various kinds, namely, 47. Seven others were engaged in similar occupations, such as sewing, washing, etc. The next largest group comprised 24 cases; they were merchants, clerks, teachers, etc. There were 11 farmers and 10 engaged in laborers' and mechanics' work. The remainder were of no especial occupation. The proportion engaged in occupations involving special exposure to wet, damp, etc., is seen to be surprisingly small.

*Age.*—The age of patients on admission was as follows:

| | | | |
|---|---|---|---|
| 1 to 10 | 2 | 51 to 60 | 19 |
| 11 to 20 | 8 | 61 to 70 | 7 |
| 21 to 30 | 19 | 71 to 80 | 2 |
| 31 to 40 | 35 | 81 to 90 | 1 |
| 41 to 50 | 17 | | |

The youngest patient was aged 4 (a case of "Still's disease"), the oldest 83, with Heberden's nodes and some changes in other joints.

*Complaint.*—The complaints made by the patients were very various. By far the largest group (36) complained of "rheumatism"; 23 complained of general joint symptoms, pain, stiffness and swelling; 20 complained especially of the pain; 10 of stiffness of the back, and the remainder of various things—6 of loss of power in the legs and difficulty in walking; 3 of sciatica; 2 of neuritis, etc.

*Family History.*—The family history is of interest. The difficulty in obtaining an exact description of an arthritis in the family history is well known. There was a definite family history of arthritis in 44 cases. Of these, 10 were undoubtedly arthritis deformans, 22 were given as rheumatism, 1 as gout, and in 11 the nature was unknown. Endeavor was made to find out if the disease developed earlier in the patients who had a family history of arthritis than in the others. The results are given in tabular form:

| Age. | Age of onset with a family history of arthritis. | | Percentage. | General percentage of onset in all. |
|---|---|---|---|---|
| 1 to 10 | 7 | = | 16 | 11 |
| 11 to 20 | 10 | = | 23 | 20 |
| 21 to 30 | 9 | = | 21 | 20 |
| 31 to 40 | 7 | = | 16 | 22 |
| 41 to 50 | 4 | = | 9 | 9 |
| 51 to 60 | 4 | = | 9 | 12 |
| 61 to 70 | 2 | = | 5 | 3 |
| 71 to 80 | 0 | = | 0 | 2 |

One case was doubtful, and is not included in the first column, and two are doubtful in the second. The percentages are so nearly alike that no positive conclusion can be drawn, although the cases with a history of arthritis show a slightly larger percentage for the earlier decades. There was a family history of tuberculosis in 28 cases, and in 9 this was associated with arthritis.

*Previous History.*—Of the ordinary acute infections, measles is by far the most common, a history of it being obtained in 68 cases. Following this came whooping cough in 31, mumps in 20, scarlet fever and malaria each in 18, chicken-pox and influenza each in 13, typhoid fever in 10, pneumonia in 7, diphtheria in 5, smallpox and erysipelas in 2 each. Tonsillitis in recurring attacks was noted only in 3 cases. There was one instance each of otitis media, bronchitis, pleurisy and carbuncles. There was a previous history of gonorrhea obtained in only 14 cases, or about 13 per cent. This, it will be noted, is in striking contrast to the percentage of 40, given in Dr. Stewart's[5] Montreal statistics. There was a history of syphilis in 4 and of chancroid in 1. Dyspepsia had been a prominent feature in 3 cases, and dysentery or diarrhea in 2. Four patients gave a history of nervous prostration; 2 insisted especially on their severe mental strain and worry for some years; 1 of great physical hardship, and 2 of working in especially damp surroundings. In regard to this latter, attention should be drawn to its apparent rarity in this series, as so many of the writers lay great stress on its importance as an etiologic factor.

---

[4] McCrae: The Journal A. M. A., Jan. 24, 1903.

[5] Stewart: Brit. Med. Jour., 1897, ii, p. 1225.

*Alcoholic History.*—Twenty-seven of the patients had used alcohol, 6 described as heavy drinkers, the remainder moderate. This is in striking contrast to the figures given in the series of gout cases reported from this clinic, where practically all were alcoholics.

*Pregnancy and Miscarriage.*—Twenty-six of the female patients had borne children, and seven had had miscarriages, varying in number from 1 to 4. Five patients had both borne children and had miscarriages.

*Onset.*—This was apparently associated with some condition in 28 cases. The patients, at any rate, thought there was some association. In 7 cases the onset was associated with exposure to cold and wet; in 3 each the onset was apparently associated with injury, diarrhea or dysentery, confinement, an attack of influenza, and an attack of measles; 2 followed closely after typhoid fever; and in 1 each it was associated with the following conditions: Very marked mental strain, constant physical strain, miscarriage and the menopause. The small number associated with exposure is to be noted. Our series of cases of acute rheumatism gave practically double the percentage. In one-half of all the cases the onset was before the age of 30, and in about one-third, before 20.

In the further study of the clinical types it is much more convenient to study each of the groups previously mentioned separately.

### GROUP I. HEBERDEN'S NODES.

This clinical group requires but little discussion. Generally accepted as undoubted manifestations of arthritis deformans, anatomically, this must be considered as usually belonging to the osteoarthritic type previously referred to. No figures as to the relative frequency of their occurrence can be given. There can be little doubt that the general idea that they are rarely associated with the more severe manifestations of the disease in other joints is substantially correct. In the present series, Heberden's nodes occurred in association with manifestations in other joints only nine times among the 94 polyarticular cases. Of these 9, in 4 the other manifestations were slight; in 3, moderate, and in 2, severe. They did not occur in association with any of the cases of spondylitis. As to the idea of Charcot that patients having these nodes were especially prone to cancer, I have no figures to offer. Certainly, one sees the association not infrequently. One point of interest in this group is the association of these lesions which we term "osteoarthritic," with those in other joints which are undoubtedly more of the "rheumatoid type." That this does occur there can be no question. It certainly speaks for a possible association of the two types.

Frankly, we have to confess that of accurate knowledge as to Heberden's nodes we have little. It can be summed up by saying that these bony outgrowths at the terminal phalangeal joints of the fingers rarely cause any troublesome symptoms, usually occur without the larger joints being involved, but may be associated with the other manifestations of the disease, although these cases are comparatively rare. In one particular they agree with the lesions in the other joints, namely, they are susceptible to injury. A blow on an affected joint is nearly always followed by some increase in the local symptoms, exactly as in the larger joints. Curiously enough, just as this was being written a patient came under observation with Heberden's nodes showing an unusual condition. She came on account of another disease. There was marked deformity of the terminal finger joints, and definite crepitus was obtained in some of them, an unusual thing in such cases in our experience.

### GROUP II. POLYARTICULAR CASES.

This comprises by far the largest number of cases in this series. There are 92, to which may be added 2 cases of "Still's disease," although in the tables these are kept separate. These cases and their clinical features show many variations, but an attempt will be made to classify them, at any rate to some extent. As already said, the changes are largely of the "periarticular" kind, and the bony changes are secondary.

*Onset.*—The ages at onset of these cases are shown in the following table:

| | | | |
|---|---|---|---|
| 1 to 10 | 11 | 41 to 50 | 10 |
| 11 to 20 | 17 | 51 to 60 | 11 |
| 21 to 30 | 18 | 61 to 70 | 2 |
| 31 to 40 | 22 | 71 to 80 | 1 |

*Method of Onset.*—This is of especial interest. On studying the cases, one finds two fairly definite kinds of onset can be recognized, namely, a sudden and a gradual beginning. Of the 92 cases in this group, the method of onset was doubtful in 6, in 45 it was gradual (in 31 of these several joints being involved together at the beginning, and in 14 one joint, others following some time later); in 41 cases the onset was sudden, in 19 of these in one joint, and in 21 in many joints about the same time. In one case the onset was in the joints of the neck. Especial attention is directed to the number of cases showing a sudden mode of onset. So many of the descriptions of the disease lead one to believe that the sudden onset is unusual, and that we see, ordinarily, a slow, gradually advancing arthritis. This point will be especially dealt with later. Of the 2 cases of "Still's disease," in 1 the onset was gradual in one joint, and in the other sudden in many joints.

*The Joint First Involved.*—This was as follows: 3, no definite history; 28, many joints involved; 3, the neck joint first involved; 5, the shoulders, 3 being only in one shoulder; 4, one arm; 1, an elbow; 3, a wrist; 1, a thumb; 1, a single finger; 1, both hands; 9, one hip; 10, one knee; 3, both knees; 1, knees and elbows both; 1, both ankles; 1, one ankle; 10, the feet; 3, the great toe; 2, other toes; 2, the joints of one leg.

*The Character of the Attacks.*—It is, of course, impossible in a disease such as this to definitely classify all the cases or the attacks. There is so much variation in the order of the joints involved, the character of the successive attacks, etc., that only an approximate classification is possible. Considering the course of the disease, perhaps three groups may be recognized. The first of these is the slow, progressive type, in which, after either an acute or a gradual onset, the symptoms slowly advance, joint after joint being involved. This may go on for a great many years. Of this class there are 44 cases. In sharp distinction comes the second class, those in which the attacks are acute and very commonly come on at intervals and at intervening times, perhaps for many years the patient may be practically free of any symptoms, although at length permanent damage is done. In certain of these cases the patient may apparently recover perfectly, or almost so, between the attacks, and it may be only after repeated acute attacks that permanent changes appear in the joints. To this class belong 29 cases. There is a third class which shows in some ways features of both the first and second groups; namely, in that they had acute attacks, but with these there was a steady progress, a certain amount of damage being left each time. In this class there were 12 cases. The remaining 7 cases it was impossible to classify.

Class 1. *The Slow Progressive Type.*—It is not necessary to spend time in describing these cases. Beginning either acutely or slowly in one or many joints, the process gradually advances, perhaps sometimes aggravated by accidental conditions, to a greater or less degree of deformity. Many joints are usually involved, the changes being rather in the periarticular structures than in the bony ones, the adjacent muscular structures showing a marked atrophy, deformities resulting, and at the last, a condition of more or less helplessness. A typical case may be briefly quoted:

No. 87.—B. K., white, male, age 40. He was admitted complaining of contraction of the legs and inability to walk. His family history was negative. The history of his present trouble was that twenty-eight years before he began to have pain in the left hip. This soon became stiff and he had difficulty in walking. After six weeks he noticed pain in the other hip, and for a time had much difficulty in walking. He then got about for a time, but always limped. Four or five months later he had a second attack and spent over a year in bed, without any acute symptoms. At the end of this time the knees gradually became involved. After some months he managed to get about, although always more or less stooped, having to walk with the hands on the knees. After a time he had to give this up and take to a wheel chair. The knees became gradually fixed, and for twenty-two years he has not been able to walk. A history in which there was never any acute attack, but only a slow continued progress.

This case, of course, showed involvement only of the lower extremities. A second case may be quoted:

No. 26.—O. F., white, female, aged 40. She was admitted complaining of pain and deformity of the joints. There was a history of arthritis on both sides of the family, and the mother has arthritis deformans. The previous history was negative. Fifteen years before, after a wetting, she complained of some pain in the left arm, which was thought to be rheumatism, was not severe, and did not last long. After this she was free of symptoms until ten years ago, when she began to have pain in the feet, especially after walking. There was no swelling, and the pain was not especially in the joints. At this time she began to notice some changes beginning in the finger joints. These gradually progressed, and for five years she had some general pains and deformity, especially of the feet and hands. During this time her general health varied. It was usually rather bad. She was very nervous. Five years ago her symptoms became very troublesome. The knees were involved, swollen and tender; pain appeared in the neck, and the temporomaxillary joint was involved. After this there was gradual swelling of the ankles, elbows and shoulders. For six months past she had pain and was almost helpless, requiring to have help in putting on her clothes, taking her meals and getting about. There was nothing acute in the symptoms at any time.

Such cases might be quoted at length, but to no purpose. The type is perfectly familiar.

Of the second group, namely, the acute, two illustrative cases may be quoted:

No. 48.—M. W., white, female, age 60. She was admitted complaining of rheumatism. She had a family history of arthritis. Her previous history was negative. At thirty-five she had an attack of acute arthritis, with swelling and pain in many joints. She was laid up in bed for two weeks. Afterward she apparently recovered completely. She had a second attack much like this at forty-five, after which she was practically well. The menopause occurred at fifty-three. Fifteen months ago she began to have pain in the great toe of the left foot. After this the knees, shoulders, elbows, wrists, and hands were all involved. The changes in the joints were more or less permanent, and she now has difficulty in getting about. She herself had noticed that the joints, although swollen and painful, were not red, and that she had no fever.

This is a fairly common history in these cases, recurring acute attacks leaving little damage, but finally permanent changes occurring. A second case in a boy of 13 may be quoted:

No. 53.—E. S., white male, age 13. He complained of swelling and pain in the feet and legs. His family and previous history were negative. His first attack of arthritis was at seven years. This lasted only for a short time, but was accompanied by severe pain. Following this he had eight or ten attacks, all acute, the first one lasting only three days. The one before admission had lasted for two months Between the earlier attacks he would be perfectly well in every way, but after the later ones it was noticed that a certain amount of stiffness persisted. The last attack was ten months before admission. He had gone to bed well. The next morning on rising he found both ankles so swollen that he could not get his boots on and he was unable to stand. Three months later the wrists became involved suddenly and remained so. On admission the involvement was in many joints.

Many histories of features much like these might be quoted, but it is unnecessary. They all serve to emphasize, however, the comparative frequency of this type of the disease. It is such histories that have suggested previous attacks of acute rheumatism as being common before the development of arthritis deformans. That all these attacks were of the one disease there seems little doubt. In the majority of these cases there is little difficulty in distinguishing them from acute rheumatism. This will be considered later in the section on diagnosis. But a point which seems worthy of emphasis is the frequency of these acute attacks. Nearly one-half of the cases of this group showed these acute manifestations at one time or other. Of the 32 cases in which there was a history of previous acute attacks after which they were practically free of symptoms, 14 had one such previous attack, 2 had two attacks, 4 three attacks, 4 four attacks, 2 five attacks, and 1 ten attacks.

There were 33 cases in which an intercurrent condition was thought to have determined the onset of another attack or further symptoms. In 8 this was an injury of some kind, usually to one joint, and followed at once by acute symptoms in it. Sometimes after this other joints followed. In 6 a wetting or exposure, in 5 an attack of dysentery or diarrhea seemed to have determined a fresh outbreak, in 2 an attack of influenza, in 2 confinement (repeated in successive pregnancies), in 2 a miscarriage, in 2 a marked shock, and in 1 each an attack of gonorrhea, an attack of measles, hot bathing, excessive fatigue, menstruation and a chancroid. Some of these may be only coincidence, but in the majority the association seemed definite.

## CONSIDERATION OF THE SYMPTOMS IN DETAIL.

In the discussion of these, especially the features pertaining to the joints, we have to keep in mind the more acute forms and the chronic deformities. With the latter especially we are familiar, and they require but little description. Along with these goes the muscular atrophy which is so common. To consider first the features in the joints:

*The Cervical Vertebræ.*—These require especial mention quite apart from the condition of spondylitis, because at some time or other in the polyarticular form it is not uncommon to have the neck involved. This was the case in 29 out of the 92 cases. This involvement we have often found to be transitory. There may for a time be pain complained of on moving, motion is much restricted, but on ordinary examination little is to be made out. Sometimes there is some deformity, the head being held definitely to one side. Judging from our cases, the condition is rarely permanent, many of the patients, especially in the acute attacks, having marked symptoms, which disappear completely as they improve. In very few of our cases has there been any permanent stiffness, apart, of course, from the cases of spondylitis.

*The Temporo-Maxillary Joint.*—This is involved comparatively frequently—in 22 cases of this series. Involvement is often unilateral and transient, but there may be all variations from this up to complete ankylosis, so that the patient may require to have teeth removed in order to be fed. This, however, has been rare in our cases. In the majority of instances there has been no permanent disability. In a few cases there was almost complete ankylosis and afterward fair recovery. One patient had teeth removed at one time, and later was able to open the mouth to a moderate extent. Involvement of this joint should be considered an important point in the diagnosis of a doubtful polyarthritis.

*The Sternal Clavicular Joint.*—This was involved in 6 instances. There was usually pain, sometimes slight swelling, and complaint of any motion involving the clavicle. It apparently is not a serious condition, and rarely causes any great discomfort.

*The Shoulder Joints.*—One or both shoulders were involved in 50 instances; of these, both shoulders in 39 cases; the right only in 8 cases; the left only in 3 cases.

In the acute attacks the patient usually complains of pain and limitation of motion, especially shown in attempts to raise the hand toward the head. It is very common to see them able to raise the hand to the level of the shoulder, but no higher. When the joint condition becomes more chronic there is usually the continuation of pain, some stiffness on handling, often definite limitation of motion, and very commonly crepitus. Fluid in the shoulder joints seems to be comparatively rare. Later there is often a certain amount of muscular atrophy of the shoulder girdle muscles, which, with the disability, often gives a very characteristic picture.

*The Elbow Joints.*—These were involved in 43 cases: Both elbows in 31 cases; the right only in 4 cases; the left only in 8 cases. In the acute attacks the elbow is usually held in a flexed position, there is often some swelling, and not infrequently a certain amount of involvement of the muscular tissues above and below the joint. This seems often more marked about the elbow than the other joints. In one case the elbow joint was opened during a moderately acute condition. The patient was thought to have gonorrheal arthritis. The muscles were found to be slightly edematous, and there was some fibrin between the muscle fibers. There were some small areas of hemorrhage. The joint contained some viscid yellow fluid. The synovial membrane showed hemorrhage and had a gelatinous appearance. In the later stages the joint may be fixed in flexion or partial flexion, but the thickening about the joints rarely advances to the extent that it often does about the knees.

*The Wrist Joints.*—These were involved in 46 cases: Both wrists in 36 cases; the right only in 5 cases; the left only in 5 cases. The changes in the wrists are often very characteristic. Only occasionally is there effusion into the joint (noted in one instance in this series), but there is often marked swelling above and below the joint, especially below. As a result of this the usual outlines of the wrist become completely lost. In the later stages we may find extreme polyarticular thickening and a certain loss of motion, although this is usually not so marked as at the elbow. Crepitus is very often obtained.

*The Hands.*—There was involvement of the metacarpal-phalangeal joints in 41 cases. The changes in these joints are usually very characteristic. In the acute attacks there may be a certain amount of redness, swelling and tenderness. As this subsides, a variable amount of thickening is left around the joints. In the later stages the thickening is permanent, mobility is lessened, there is usually flexion of the joints, and, not uncommonly, some subluxation. It is not uncommon to find some of these joints involved and others free. In six other cases of the series there is only a note that the hands were involved, which probably means these joints.

*The Fingers.*—These were involved in 52 cases. The thumbs were only involved in 7. The changes in the fingers were often very characteristic. In the acute attacks there may be but little visible change. There is some swelling and limitation of motion, but no great deformity. Subsequently, the thickening about the joints becomes more marked, and the typical "pod-shaped" or fusiform finger is produced. In the later stages we have a great variety of deformities. A common form is a flexion of the first phalanx with hyperextension of the terminal ones, but all the joints may be partially flexed, or only the terminal one be hyperextended. With this one may have also lateral deflection, especially of the terminal joint; and in some cases subluxation may result.

There are several features associated with the hands worthy of note. The patients are rarely able to "make a fist." There is very commonly ulnar deflection of all the fingers, which probably means only the position of greater ease. There are some other features which may possibly not be associated so much with the joints as with other structures. One of these is sudden weakness of the wrist joint, so that the patient drops articles which are being held. This is not an uncommon occurrence, sometimes happening in the earlier stages. Another point is the complaint of pain about the ball of the thumb, or on the ulnar surface of the wrist. This may be found in certain instances quite apart from any active arthritis, and it seems worthy of being noted. In certain cases one notes atrophic changes about the hands. In others the nails are ribbed, or show coarse markings. The skin, in common with that of other parts of the body, may be glossy and shining.

*The Hip Joints.*—These were involved in 31 cases: Both hips in 25 cases; the right only in 3 cases; the left only in 3 cases. It is not uncommon to have complaint made of pain in the hip joint during an acute attack, but on examination nothing very definite is to be made out except tenderness. In the later stages there may be, as in other joints, more or less permanent deformity. The joint becomes fixed, often with the thigh slightly flexed and more or less abducted. The changes are often not as marked as in the cases with monarticular disease of the hips or spondylitis.

*The Knee Joints.*—These are by far the most frequently involved in the cases of this series, there being a total of 80 cases. The next most frequent of the single joints is the shoulder. The figures are: Both knees in 65 cases; the right only in 7 cases; the left only in 8 cases. Effusion occurs in the knee joint with considerable frequency, this being quite marked in 14 instances.[6] The knee joints in the acute attacks often show nothing very characteristic. There is some redness, swelling and tenderness. In later stages the joint commonly becomes somewhat fixed, and there is very often crepitus and marked thickening in the polyarticular structures. Along with this frequently goes marked thickening of the capsule. This can be readily appreciated by running the thumb up and down the inner surface of the joint opposite the interval between the two bones. A thickening of the capsule can thus be very readily perceived, and the thickened folds readily felt. One is often deceived into thinking that there is marked enlargement of the bony parts of the knee joints, whereas this appearance. is due principally to the periarticular thickening and muscular atrophy above and below the joint.

---

[6] It is, of course, often difficult to be certain of the presence of small amounts of fluid in a joint. Probably it occurs much more frequently than figures generally indicate. In all these cases the presence of fluid was established beyond a doubt.

*The Ankle Joints.*—These were involved in 48 cases: Both ankles in 37 cases; the right alone in 5 cases; the left alone in 6 cases. The ankles show often much the same features as the wrists. There is considerable swelling about the joint, and there is stiffness and restriction of motion, with but comparatively little change in the joint itself.

*The Feet and Toes.*—There was involvement in some of the joints of the feet in 11 cases; of the toes in 10; of the great toe only in 6. The disparity between the involvement of the fingers and of the toes is very striking. Notice should be directed to the cases having involvement only of the great toe among the joints of the feet. In a doubtful case this suggests gout, but the changes in the other joints may be characteristic.

*The Symmetry of the Joint Involved.*—The majority of writers are very fond of laying emphasis on the symmetry of the disease, but, as will be noted from the figures given before of joint involvement, in a considerable number of instances only one joint was involved. For example, in 11 out of 50 cases of shoulder joint involvement, the disease was unilateral; in 12 out of 43 cases at the elbow joint; in 15 out of 80 in the knee joint, etc. The total number of instances of involvement of the joints of the upper extremity was 238, and of the lower extremity 186. The larger joints of the leg were involved 159 times, and those of the arms 126 times. The preponderance of joint involvement was markedly in the upper extremity in 4 cases, in the lower extremity in 12. This preponderance is, of course, analogous to the greater frequency of the involvement of the large joints of the leg. In only three instances, however, were the joints of one side of the body involved to the exclusion of the other side. One pair of joints only were involved in 3 cases, in 2 the knees, and in 1 the wrists.

How satisfactory the explanation sometimes given may be (namely, that the joints most involved are the ones most in use), there can be little doubt that, as a general rule, the large joints of the legs suffer more than the large joints of the arms. The hands suffer more than the feet. In reference to the association of the polyarticular forms with Heberden's nodes, the figures have already been given. Of the cases with spondylitis there was involvement with the other joints in 8 cases, in 4 of which there were multiple joints; in 1 in the hands; in 1 in the shoulders; in 1 in the knees and hips, and in 1 in the knees, hips and ankles.

*Effusion.*—The fluid obtained by aspiration is usually somewhat turbid, and contains a certain amount of granular material, with polymorphonuclear leucocytes. We have never found a hemorrhagic exudate.

*Muscular Atrophy.*—This is present in the majority of cases, but it is well to remember that in certain of the acute forms with a short duration there may be but little atrophy until after successive attacks. This is not invariable, for even after a short duration of symptoms in some cases there may be quite marked atrophy. The significance of this it is not the purpose to discuss here, nor to what extent it suggests a diseased condition in the central nervous system. The atrophy is often characteristic and striking, especially with the appearances in the joints. This is often true of the hands when the wasting of the interossei gives a very typical picture. The rapid onset of this sometimes gives a clew to the diagnosis in a doubtful case.

*General Joint Features in the Acute Attacks.*—Reference may be made to these, especially as there is so much difficulty in distinguishing the condition from acute rheumatism. There is usually a polyarthritis, but rarely any succession of joints becoming involved and then clear, as in rheumatism. A joint when once attacked is rarely free until the attack is over. There is usually considerable pain, moderate swelling, which may extend above and below the joint (especially in the elbows, wrists and knees), at times redness, but not as marked as in rheumatism, sometimes some heat, and rarely extreme tenderness. If with these features there be involvement of the joints of the hands or fingers, of the cervical vertebræ or temporomaxillary joints, the diagnosis is fairly certain. With these local conditions there is usually not high fever (often surprising when the degree of arthritis is considered), but a rather rapid pulse rate. There is rarely endocardial involvement. To sum up, a polyarthritis which does not shift about, slight fever and a rapid pulse, are the most striking features. As time goes on the fact that the joints change very little, the arthritis persists and the usual rheumatic remedies are of little avail, all help to decide the diagnosis. After the subsidence of the acute features the persistence of thickening about the joints is a suggestive feature.

*Temperature.*—Of this there were records in 86 cases, the remaining patients not being in the hospital long enough to obtain a complete record. Of these the figures are as follows:

| | |
|---|---|
| Normal | 15 |
| An average of 99 | 28 |
| An average of 99 to 100.0 | 21 |
| An average of 99 to 100.5 | 5 |
| An average of 99 to 101.0 | 10 |
| An average of 99 to 102.0 | 1 |
| An average of 99 to 103.0 | 1 |
| An average of 100 | 1 |
| An average of 100 to 102.0 | 1 |
| An average of 101 to 102.0 | 1 |
| Irregular | 2 |

Of the two irregular cases, in one the temperature varied from 99 F. to 105 F. This was associated with a general pneumococcus infection and death. In the other case the patient had a severe shaking chill, and the temperature arose to 104 F.; the only instance in the series where a severe shaking chill was noted.

These figures of the temperature records are of considerable importance. It will be seen that only fifteen cases, or 18 per cent., had a normal temperature, and that the great majority, fifty-nine, had a temperature averaging between 99 F. and 101 F. This is a point of considerable aid in the diagnosis. The majority have fever, but it is usually not high.

*The Circulatory System.*—There are notes of the cardiac condition in only 74 cases. Among these the heart was perfectly clear in 55. There was a soft systolic bruit, apparently not organic, in 10. In 2 there was marked irregularity, and in 7 an organic lesion. Among these latter cases there were 3 of aortic insufficiency, 2 of mitral stenosis and insufficiency, and 1 each of mitral insufficiency and mitral stenosis. In some of these the condition was associated with marked general arterial sclerosis, and probably the cardiac condition was due to this.

Of much greater significance are the records of the pulse rate. Of the 78 cases in which there were long enough records to note, the figures were as follows:

| | | | |
|---|---|---|---|
| 70 to 80 | 9 | 100 to 110 | 10 |
| 80 to 90 | 17 | 110 to 120 | 7 |
| 90 to 100 | 24 | 120 to 130 | 2 |

It will be seen that in two-thirds of the cases the pulse rate was above 90. This may be not only with the acute attacks, but also in the conditions characterized by more or less slow advance. We have found it of considerable aid in the diagnosis, especially in association with slight fever.

*Urine.*—This showed practically nothing abnormal. In 83 cases it was clear in 64, contained a very slight trace of albumin in 9, and albumin and casts in 10. Sugar was found in one instance. Determination of the total excretion of uric acid was made in a number of cases, but always with the finding of the normal amount.

*Glandular Enlargement.*—Of 33 cases of which we have careful records there was general glandular enlargement in 13, definite enlargement of some of the glands in 4, and no general enlargement in 16. This condition would probably have been found in many other instances had it been carefully looked for. In the majority of cases, at any rate with acute features, the glands in association with the affected joints are enlarged. This is worthy of note as supporting the view that the condition is an infective process of some kind.

*Spleen.*—Of 39 cases where there are careful notes, the spleen was found enlarged in 4, and in 35 no increase in size could be made out. This is a point of considerable interest, especially in association with the cases of "Still's disease," in which the enlargement of the spleen is such a marked feature.

*Subcutaneous Fibroid Nodules.*—Of these there are the surprisingly large number of 7 cases, and one additional doubtful case, in which the enlargement seemed to be in association with the tendon. Regarding these nodules, there is no doubt that they are found exactly in proportion as they are looked for. In this clinic careful search is usually made for them, and in all these cases their presence was confirmed by Dr. Osler's note. These figures give a percentage of 7.4, which is very much larger than in the instances among our cases of acute rheumatism (namely, 1.5 per cent.). The opinion is now fairly general that these nodules are not essentially rheumatic, although some writers would have us believe that they were absolutely diagnostic of a rheumatic condition. Of special note is the age of the patients in whom they were found. One was 27, one 33, and all of the others over 50 years of age. In rheumatism these nodules are almost always found in children.

*Pigmentation.*—Marked pigmentation was noted in 8 cases of the series, but it is doubtful if this represents the total number, had it always been noted. Some writers, especially Spender, have laid emphasis on the occurrence of brown pigmented areas about the forehead, face and forearms, especially as being often diagnostic. If one follows for a time the general incidence of these pigmented areas among all patients they seem to me to be about as frequent in other conditions as in arthritis deformans.

*Blood.*—The average percentage of hemoglobin in 33 cases was 70.6, and the red cells in 29 cases, 4,468,000. These figures seem rather high when one remembers the very frequent pale, anemic look of these patients; but the pallor is often more striking than the actual anemia. The average leucocyte count in 33 cases was 7,600. Of these in only 9 was the count over 10,000. In two of these the leucocytosis was probably due to other conditions. In one with an acute pleurisy the leucocytes arose to 18,000; in the other the count of 15,000 was associated with a general pneumococcus infection. These two counts are not included in the average. Of the remaining 7 cases it is interesting to note that in only 2 were the counts taken during acute attacks, rather a surprising result. In 6 cases the leucocytes were 5,000 or lower. Full differential counts were made in 8 cases. These gave an average of: Polymorphonuclears, 76 per cent.; small mononuclears, 14 per cent.; large mononuclears and transitionals, 8 per cent.; eosinophiles, 1.5 per cent.; mastzellen, 0.5 per cent. These are practically normal findings.

*Reflexes.*—The study of these is of interest, especially as some writers, R. L. Jones,[7] for example, attach some importance to them in the diagnosis. In the cases of this series there are not enough complete reports of the reflexes to draw any conclusions. But the general rule seems fairly well established that the reflexes in association with affected joints are usually increased. This was very evident in some of our cases where the involvement was asymmetrical. On the side affected the reflexes were exaggerated, but normal on the sound side. Whether the explanation lies in the changed local condition or alterations in the cord, is difficult to say. In addition to the deep reflexes, the superficial ones are often much exaggerated, which we have found especially true of the cremasteric reflex. This rather speaks for other than a local cause.

But the findings are not constant. The cases are so variable and the conditions so different that this may later be easily explained. Practically, the reflexes in different cases have been found exaggerated, normal, or decreased, but rarely absent. Ankle clonus was obtained in a few instances, but we have never obtained a definite extensor response to plantar stimulation.

How strongly the conditions of the reflexes speak for spinal cord involvement it hardly seems yet possible definitely to say.

*Unusual Features.*—These require no special mention. They comprise: Pleurisy, 2; severe diarrhea, 2; chill, 1; jaundice, 1; abdominal pain, 1; mental features, 1; purpura, 1; enlarged thyroid, 1; bronchitis, 1; paralysis, 1. The case with severe abdominal pain is of interest, as there have been cases with like features reported both in acute rheumatism and gout.

### PATHOLOGY.

This is again one of the doubtful points in the disease. Until we are certain of the etiology we can determine the morbid anatomy only. The essential element in our knowledge of the pathology is lacking. It is not the purpose here to discuss the various opinions at length. The two principal views are that the disease is (1) due to an infective agent (either a specific organism or a variety of organisms or their toxins) or (2) of neural origin.

For the infective view there are many suggestive points. Here, of course, only the polyarticular form is discussed. The mode of onset, often sudden, with involvement of many joints, the fever, increased pulse rate, are all in favor of an infection. The subsidence of these after a time, often to recur in subsequent attacks—the interval perhaps having been free of symptoms—and usually first or last the appearance of permanent changes about the joints are all important. In some patients there is permanent change dating from the first attack, in others this may only occur after repeated attacks. These seem comparable to the condition often seen in the endocardium of rheumatic patients. A first attack may leave the valves permanently damaged, or only more liable to involvement in subsequent attacks.

---

[7] The Lancet, Dec. 27, 1902.

Could we determine a definite organism to be associated with the disease, the matter is settled. In this series we have never succeeded in obtaining any results from cultures, in spite of the greatest care in following the methods given (for example, by Bloxall). If we hold the view that many organisms (such as those of influenza, gonorrhea, etc.) are etiologic factors, there are many suggestive facts to support this. There seems no doubt of the association of attacks or exacerbations with various infections such as influenza. This may mean only lowered resistance, for we find this an important factor. Ill health from any cause, anemic or depressing conditions, may all apparently precipitate an exacerbation or another attack. In reference to the association with, for example, previous gonorrhea, it has already been noted that the disease is here very uncommon among the colored race, among whom gonorrhea is almost of general occurrence.

Some features are usually referred to as being much in favor of a neural origin, such as the rapid muscular atrophy, the curious association of alteration in reflexes, such as between the gluteal and plantar, etc. Of the rapid muscular atrophy there can be no doubt. It may occur long before there is any possibility of disuse producing it. After a very prolonged attack of acute rheumatism there may be considerable atrophy, but rarely with the rapidity and certainly not with the certainty of its development in arthritis deformans. The association of the reflexes often follows their segmental distribution, as may also the curious localized distribution of the lesions in the hands. Thus the middle and ring fingers only may be involved, or show special changes. In another case the thumb and first finger may show the same association. These may speak for primary spinal cord involvement, but the explanation suggested that they may be due to changes due to toxic substances seems worthy of note. The changes found in the posterior columns of the cord do not seem necessarily primary. We know that they may be found with any chronic toxic condition, as, for example, diabetes or pernicious anemia. May not the chronic cases of arthritis deformans with suggestive nervous manifestations possibly belong to the same class?

A point worth noting is the occurrence of enlarged lymphatic glands in many of the cases, nearly half of these where we have complete records. In the so-called "Still's disease" they are very marked. This is no more than we might have expected, if this be regarded as a form of arthritis deformans. The glandular system of children reacts more markedly to toxic absorption than that of adults. This glandular involvement seems to support the view that we have a toxic condition, probably due to some infection.

While the whole question must as yet be left open, the evidence seems to point more to the infective theory. Toxemia, secondary to infection, explains some, at any rate, of the nervous symptoms.

*Morbid Anatomy.*—Here again, in the majority of descriptions, we find only the late changes described. Opportunities for autopsies in the early stages are very rare. To describe the late changes throws no light on the condition. The majority might come from any long-continued degenerative joint condition. It is these that the majority of the writers have given as the pathologic anatomy.

One of the most important of recent observations has been made by Dr. Hale White, who had an opportunity to examine a comparatively acute case postmortem. In a proximal interphalangeal joint with marked changes he found that the most marked alteration was in the synovial membrane. This showed the formation of new fibrous tissue, and evidence of both recent and chronic inflammation. The membrane on the cartilage opposite the thickened fringe showed thickening, and the formation of fibrous tissue. The cartilage beneath this was thinned and eroded, and in places the erosion had gone through the cartilage. In connection with these areas there were foci of inflammation in the bone, but these changes were slight in comparison with those found in the synovial membrane. The synovial fringes in the knee joint showed no bony deformity, only the usual "thinned" condition of the ends of the bones so characteristic of these cases.

The only case of this series coming to autopsy affords but little information, so far as concerns the morbid anatomy of the disease. The patient was admitted with a general pneumococcus infection, with which was a pneumococcus arthritis. He had symptoms of arthritis deformans for over two years. The joint changes had gone on to erosion and eburnation of the bones. Each knee joint contained about 100 c.c. of purulent fluid. The synovial membrane was much thickened and injected, and there was evidently much overgrowth of connective tissue. Sections of these showed the surface covered with an exudate consisting of granular material and of polynuclear leucocytes. Below this was a layer of flat endothelial cells which merged into underlying fibroblasts, under which were many blood vessels and polynuclear leucocytes. Next to this layer was much fibrous tissue. These all seem to speak for inflammatory changes more than degenerative, at any rate in the early stages.

The findings—few though they be—all speak for an inflammatory condition at the onset. Degeneration comes later, but the beginning seems rather due to inflammation beginning in the synovial structures. This suggests infection, rather than neural causation.

Some writers have laid stress on various septic conditions, such as pyorrhea alveolaris. This may have some causal association, but its occurrence is so nearly universal as to throw doubt on its importance.

(*To be continued.*)

# ACUTE OTITIS MEDIA;

## THE NECESSITY OF AN EARLY DIAGNOSIS AND TREATMENT.*

FRANK D. BOYD, M.D.
Professor of Physical Diagnosis and Hygiene, Medical Department
Fort Worth University.
FORT WORTH, TEXAS.

It is necessary that we make an early diagnosis of acute otitis media: 1, Because of pain which usually accompanies all acute attacks; 2, because of deafness which very frequently follows, and 3, because of the frequent danger to life by extension of the inflammation to the brain. If we consider the anatomy of the middle ear, with its proximity to surrounding parts, we readily see how important it is to examine our patients as early as possible and relieve the disease before an inroad is made into these dangerous fields.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

The middle ear, or tympanum, is situated within the petrous bone, and is an irregular cavity, the carotid canal lying in front and the mastoid cells behind, the meatus auditorius externally and the labyrinth internally. The tympanic cavity consists of two parts, the tympanic cavity proper opposite the tympanic membrane, and the attic, or epitympanic recess, just above the level of the upper part of the membrane. Its boundaries are externally the membrana tympani and meatus, internally the outer surface of the internal ear. It communicates in front with the eustachian tube and canal for the tensor tympani. It communicates behind with the mastoid antrum, and through it with the mastoid cells. It is exceedingly important that we should not overlook this proximity to the opening into the antrum through the posterior wall of the tympanic cavity. This opening is a large irregular aperture which extends backward from the epitympanic recess and the antrum mastoideum. This communicates with the mastoid air cells contained in the interior of the mastoid process, and we should remember that this same mucous membrane, found lining the tympanic cavity, continues into the antrum, thereby giving a direct course through which a very simple inflammation of the middle ear frequently results from an inflammation of the nose or throat due to some pyogenic infection, extending through the eustachian tube into the tympanic cavity, from there into the epitympanic directly into the mastoid cells. Thus are endangered the lives of our patients, a matter on which it is unnecessary to dilate.

Usually the first symptom is pain, commonly termed "earache." This is so common in some families that I am prone to believe that there is often an inherited tendency to this trouble. No doubt many of you have had whole families who have suffered with "earache," especially the smaller children. In nearly every case this is an actual inflammation of the mucous membrane lining the middle ear, extending through the eustachian tube. A child suffering with "earache," so often overlooked, I am afraid, by the "good old family doctor," is always in danger of deafness, and we should not spare any care to relieve this trouble, and warn the family of the danger. It is so often found that the ear thus affected is rarely restored to perfect hearing. This fact often escapes the notice of the family until many years after if only one ear is affected. The pain may be a dull ache or very acute. Often these attacks are at night, becoming so severe that the whole family is aroused, and the laudanum and sweet oil are forthcoming. Frequently in young children the seat of the trouble is never found, and often in a few days the nurse or some member of the family discovers a "running" ear, and perhaps the aurist is called in, but too often at that stage the hearing is partially lost.

The first thing asked of the aurist is to relieve pain. That is of paramount importance to the patient as well as to the family. Any physician can make the correct diagnosis. The use of the head mirror should be common to every medical man, and with that and a light, either from the window or a lamp, the inspection of the drumhead is easily made. In the examination of no part of the body is it so important for us to practice that delicacy of touch as in the handling of an inflamed ear. It is, indeed, important for the patient's welfare, and also for the physician's, as a rough handling is never repeated in that case, unless by force. If the conditions are such that a thorough examination can not be made give a general anesthetic and make it thorough. If the drumhead is bulging and pain intense, the first thing that should be done is a thorough paracentesis of the tympanum, and the sooner it is done the earlier the inflammation subsides and the less destruction of the parts results. If the drumhead is allowed to rupture spontaneously the disease runs longer, there is greater susceptibility to loss of hearing and more danger to the mastoid, and more liability to other complications which endanger life. It is my experience that if the membrana tympani is punctured early and the secretions allowed to drain, the disease is cut short, and complications are exceedingly rare.

MacLeod Yearsley[1] has this to say regarding the necessity of early recognition of ear trouble in children:

> The frequency of deafness in children due to failure on the part of the attending physician to recognize the existing ear affection in infancy is to be deplored. Often it is not until long afterward that the real trouble is appreciated, and it is then too late to effect a cure by treatment. Pain in the ear is due to inflammation or non-inflammatory affections. The latter, neuralgic, is rare in children. Loss of weight and elevation of temperature should always demand an examination of the ears. Hartmann regards intestinal disturbances in infants suffering from otitis media as being due to the reabsorption of the toxic poisons from the exudate in the tympanic cavity rather than as a result of infection entering the eustachian tube during the act of vomiting. To the general practitioner the value of exclusion of ear disease can not be overestimated.

Dr. Otto J. Stein,[2] writing on middle ear disease and its relation to the cranial cavity, says:

> In the entire human economy there is not a single cavity which is of such vital, relative importance to its neighboring structures as that of the middle ear. It bears such important relationship to all which lies about, hidden away as it is deep down in the firmest and hardest bone of the body, that oftentimes it is the very thread from which suspends the sword of Damocles.
>
> Disease in this region means not only deafness, noises in the head, discharge and dizziness, but, when not properly recognized and taken in hand, results in invasion of the cranial cavity and perhaps death. The very fact that it is a small cavity, not readily visible and tucked away in so strongly fortified position, that when disease runs riot within its walls it lays the entire adjacent territory open to infection and invasion, is sufficient reason why more study, more careful analysis and sober consideration should be given to any sign or symptom pertaining to the ear. Only a few years ago the profession was taught to disregard a chronic discharge from the ear, with the admonition that to check it would be dangerous, therefore, to let it alone to take care of itself. This idea of the subject took its origin, presumably, from the fact that many cases attended by spontaneous cessation of the discharge became worse and died. As a result of this teaching the laity came to regard a running ear as a most natural state of affairs, which to interfere with or check by any means would tend only to complicate matters. Formerly patients had to be satisfied with such advice from their physician, because of an undeveloped state of the profession's knowledge, but the day of such ignorance and omission is past.

In conclusion, we should first consider earache as a warning note of danger to the patient both as respects function of hearing and life.

Second, in making the diagnosis, especially as to the inspection of the trouble, we should avoid opiates as much as possible, for they always mask the symptoms, and it would be difficult to thoroughly diagnose the extent of the disease. If the membrana tympani has not already ruptured, after we have made a diagnosis we should perform paracentesis, whether there is much bulging of the membrane or not, for the incision of the drum membrane is important to hasten the evacuation of the pus or serum that is contained behind the tympanum and also to relieve the pain.

## DISCUSSION.

Dr. H. Dupuy, New Orleans—Free incision of the tympanic membrane is, of course, the only surgical procedure adapted to such cases, but Dr. Boyd did not lay sufficient stress on the anesthetic. Must we use general anesthesia, or have we any satisfactory local anesthetic? In our Eye, Ear and Throat Hospital we use solutions of cocain, anilin oil and absolute alcohol. We use an 18 to 20 per cent. solution of cocain in a solution of equal parts of anilin oil and absolute alcohol. I am sure we have used that solution over 800 times. We fill the canal with this solution and allow it to remain for 10 or 15 minutes, after which time the drum is usually sufficiently anesthetized to permit a free incision. I have been asked by Dr. Cobb what has been our experience with the addition of anilin oil. In all those cases only one did not do well. In that case there was a perforation, and I had the solution instilled into the ear, twenty drops every hour. At that time we knew very little about the effects of the oil. At the end of the third hour I had a most violent case of toxemia. The patient was deeply cyanosed, pulse 165, temperature subnormal, and death seemed imminent. But remember that in this case there was a solution of continuity. The patient was suffering very much, and we injected the solution to secure relief, intending the next day to introduce a more formidable procedure. We have tried menthol and a number of other preparations, and we have decided that if the anilin oil mixture were not satisfactory we would resort to general anesthesia.

Dr. Philip Hammond, Boston—Some four or five years ago, at the Massachusetts Infirmary, we made some experiments to find a satisfactory local anesthetic. Cocain would not penetrate. Cataphoresis, as dentists employ it when working about the teeth, apparently had no effect. Two or three years ago I employed the formula of which Dr. Dupuy speaks. It was used in my clinic one fall and winter session by different observers on a number of cases, although I saw most of the patients myself. I could not see that it had any effect. Some patients will not feel paracentesis anyway. There are cases of great pressure inside the tympanum, with bulging of the drum, in which there is no pain from paracentesis. But in high-strung nervous patients, especially of the better class, this solution had no effect.

Dr. Edward C. Ellett, Memphis, Tenn.—Experiences seem to differ. I have been using the menthol-carbolic acid mixture for four or five years, probably about a hundred times, and I have never failed to get a perfectly satisfactory anesthesia of the drum. The solution is simply painted on the drum with a very small wisp of cotton twisted on the end of an applicator, small enough not to obscure vision. The effect may be all due to the carbolic acid for all I know. The discoloration produced indicates how far the anesthesia extends. I have performed simultaneous double paracentesis with this solution without a particle of pain, and I have employed it on children two years old without the manifestation of any more reluctance than they would exhibit to the use of the ear speculum or the applicator. I use equal parts of cocain, menthol and carbolic acid, rubbed up to a liquid. I was glad to hear mention of the pain after perforation of the drum; for, from the text-book and journal articles, I had almost come to think that I must be the only man who had pain continue after the operation.

Dr. D. A. Kuyk, Richmond, Va.—Although so many cases are reported in which the cocain and anilin oil solution has been used without difficulty, I think we should warn the general practitioner as to its danger. I have had two cases of acute poisoning from this solution; in one the drum was perforated. In one case, a child of 3 years, after the use of four or five instillations of the solution the child's face became blue and pinched, the eyes glassy, the pulse so rapid it could not be counted, and death seemed imminent. Hypodermatic injections of strychnia, the use of hot water bottles and various methods of resuscitation were required to save life. The other case was a man 65 years old. The shape of the canal was such and there was so much swelling that the drum was hardly visible. I wanted to open the external meatus, but he would not consent. The pain was marked. Four instillations of the solution were made by a trained nurse at hour intervals. In about four hours he began to have the classic symptoms. The nurse thought it was only the depression from pain and paid no attention to it. The next morning she telephoned me and asked whether to instill any more of the anilin oil, because the pain was returning. It was several days before the patient was able to walk about the room. As specialists we may use this preparation with comparative impunity, but we should warn practitioners and druggists against giving cocain and anilin oil for the relief of pain. The frequent use of cocain is a sin of commission every day. Druggists tell me that the very beginning of the cocain habit is frequently a spray or ointment prescribed for a patient.

Dr. Harmon Smith, New York—In the hospitals of New York City we have tried the various anesthetics. The one mentioned by Dr. Dupuy is the one we now use more than any other. We have not yet met our Waterloo, but sooner or later we will find a patient with a peculiar idiosyncrasy to cocain. In my opinion, anilin oil anesthesia is the most potent of local remedies in rendering paracentesis painless. Nitrous oxid is more satisfactory, however, than any local anesthetic.

Dr. Charles H. Baker, Bay City, Mich.—Anilin oil may produce the same effects that are caused by acetanilid in excessive doses. It is not the cocain so much as it is the anilin oil that causes trouble. I was recently asked by a physician for the composition of the drops that I had used the day before on his daughter. Both drums were intact. Symptoms like acetanilid intoxication were present, and I immediately instructed them to discontinue the instillations. In another case, in which the mixture was used by a physician for earache, it required considerable stimulation to bring the child through. I am in the habit of using this mixture in selected cases only, so that the two cases mentioned occurring in a comparatively small number of cases would seem to show considerable danger in the use of the solution. The instillation of quantities *ad libitum* should be prohibited, and the remedy should be watched.

Dr. D. A. Kuyk, Richmond, Va.—Perhaps the chemical combination of the cocain and the anilin oil does the damage; either one alone might not have the same poisonous effect. I have used them separately without bad effect.

Dr. Lewis G. Woodson, Birmingham, Ala.—I think the possibility of cocain intoxication is rather exaggerated. I do not believe that cocain, used alone, has any appreciable effect in producing anesthesia of the drum membrane. In the mixture with carbolic acid, for instance, the carbolic acid is the useful agent. For a number of years I have been using a 20 per cent. solution of carbolic acid in glycerin before incising the drumhead; this renders the operation practically painless. Before operating, this solution is also useful for sterilizing the auditory canal. I doubt very much whether solutions of cocain are ever absorbed by the drum membrane. If they were absorbed, anesthesia would follow in all cases, as we do in other parts of the body. It is only when a perforation exists in the membrana tympani and cocain makes its way into the tympanic cavity that toxic symptoms are developed. I have frequently used from 20 to 30 per cent. solutions in the ear without producing the slightest evidence of toxemia. In adults one can very often, if there is much tension, incise the drumhead freely without any anesthesia. In some cases it is better to use general anesthesia; for this purpose gas is probably the best and quickest.

**Dr. J. F. Barnhill**, Indianapolis—If the fluid in the middle ear is catarrhal and the disease limited to the atrium of that cavity, local anesthesia, while not complete in any case, is here indicated and usually sufficient. But in purulent cases in which the disease has attacked the attic, and the inflammation is of a violent nature, the paracentesis, in order to do the good that is expected from it, must be extensive and extend into the mucous membrane of the middle ear, cutting through the reduplications found in the attic and extending into the skin of the external meatus for some distance. This procedure is always and most satisfactorily done under general anesthesia. I have believed that anilin is the most efficacious of the local anesthetic mixtures. I have had two experiences from its use which were entirely unsatisfactory; in each of the cases a diphtheritic exudate formed, covering the skin of the entire external meatus and very greatly prolonging the disease. I have also had one similar experience follow the use of carbolized glycerin for the same purpose.

**Dr. George L. Richards**, Fall River, Mass.—Paracentesis simply means a puncture, and the average general practitioner whom we are trying to teach will probably get a small spear-shaped knife and puncture the drum membrane slightly and report that he has done a paracentesis. If we would say that we make a free incision of the drum membrane, it would be plainer. I think, as otologists, we should drop the term "paracentesis" altogether.

**Dr. Kate Baldwin**, Philadelphia—I have found from several years of careful observation that many cases of earache, especially in children during the first and second dentition and even up to the eruption of the wisdom teeth, are to be ascribed almost entirely to the process of dentition. In those cases a thorough free incision down on the tooth will relieve the earache. If this is done before pus is formed it will make unnecessary any puncture of the drum. I have gone over this subject very thoroughly, having a dentist in connection with the clinic, and I think it is a matter worthy of your consideration.

**Dr. Walter R. Parker**, Detroit—I have secured my best results from carbolic acid as a local anesthetic. Cocain has not seemed to work so well. Much depends on the method of application. In five or six cases I have used pure carbolic acid, and with absolute alcohol controlled its action completely.

**Dr. C. M. Cobb**, Boston—I am afraid of cocain, and I am a good deal more afraid of anilin oil. I prefer to hurt my patients a little rather than to explain to the family how they happened to die. The use of even a weak solution of carbolic acid may produce very decided and extensive tissue necrosis. Dr. Frank Harrington, Boston, reported a necrosis of the entire finger of a workman from the use of a 2 per cent. solution of carbolic acid. When carbolic acid is applied to the drum, I think trouble is more likely to ensue from prolonged suppuration and the patient is likely to be left with a more damaged ear than if cocain or nothing was used. Of course, one can neutralize the carbolic acid with alcohol, but that is not the procedure that has been very generally recommended.

**Dr. J. F. Hill**, Memphis, Tenn.—I have tried a little of every anesthetic, and I have found nothing to equal the preparation Dr. Ellett mentioned. That can be used with perfect satisfaction on children two years old who are crying with earache. I have hundreds of times relieved the condition without free incision by forcing 3 or 4 drops of equal parts of spirits of camphor and chloroform into the middle ear by Politzer's bag. The air in the middle ear becomes stagnant, and it is purified by this solution being thrown through the eustachian tube into the middle ear.

**Dr. W. Scheppegrell**, New Orleans—If carbolic acid is used only for the incision of the drum, and if its effects are carefully watched, it is useful. But there is danger in its being used for the relief of pain. We can not use carbolic acid in the auditory canal for the relief of pain without danger. If it comes to be used by the laity as they now use cocain, we will surely have many deleterious effects. Its use should be restricted to the incision of the tympanic membrane and its effects at once neutralized.

**Dr. F. D. Boyd**, Fort Worth, Texas—When I selected the title of this paper I knew that all would agree as to the necessity of an early diagnosis and treatment, but I expressed the views in the paper for the benefit of general practitioners and avoided outlining the treatment, etc., because the paper would be prolonged. I agree that "paracentesis" is not a good word, because we make free incisions, and a paracentesis is generally understood as a simple puncture. I have tried cocain in various ways, and have never found it beneficial. I have been forced to resort to a general anesthetic when making a free incision into the drumhead. If we want to relieve a case early and get the best effects, it is better to give some general anesthetic. Often we do not see the patients early; they come to us secondarily, after they have been to the family physician.

# SOME RECENT EXPERIENCES WITH CHRONIC SUPPURATIONS OF THE EAR.*

PHILIP HAMMOND, M.D.

Assistant in Otology, Harvard University; Assistant Aural Surgeon, Massachusetts Charitable Eye and Ear Infirmary.

BOSTON.

Discharge from the ear is regarded by most patients as disagreeable, but few recognize the fact that it is a distinct menace to life. After the acute symptoms of abscess formation have subsided, the absence of pain may lead to the neglect of the discharge, or the secretion may be so slight in quantity as to escape observation, and in this way become chronic. With any long-continued suppuration there is very apt to be some invasion of bone tissue and consequent necrosis. In the ear, around which center so many important structures, this is an especially dangerous condition, the more so as the erosion of the bone is insidious, the patient experiencing no discomfort whatever. This carious process usually attacks the ossicles first, and is often limited to them, but later spreads to the main bone. The bone separating the ear cavity from the brain and the large blood vessels varies so in thickness that it is impossible to know when perforation is going to take place. The only safe way is to absolutely stop the discharge.

Of the three cases reported here, the first is a good illustration of the beneficial results of operative interference before the disease has extended beyond the ear. The other cases show equally the folly of allowing a suppurative process to continue within the temporal bone, even although the patient suffers no inconvenience from the disease.

Case 1.—A young lady with a history of discharge from the right ear three years ago had some treatment at that time and shortly after was assured that the ear was well. There had been no further disturbance in the ear otherwise than some deafness, until a few months before I saw her, when she complained of extreme tenderness about the right ear and side of the head, with some vertigo and nausea. There was with this some purulent discharge. The dizziness became almost constant and was marked when she came to see me. Examination of the right ear showed a large destruction of the drum, with much inspissated pus. With the middle ear probe caries was felt in the region of the incus. There was also a mucous polyp springing from the lower part of the tympanic cavity. The patient was advised to have the ossicles removed, and this was done two days later. Under general anesthesia the remnant of the drum membrane, the malleus, incus and the polyp were removed. Further probing failed to discover caries of the main temporal bone. Subsequent examination of the bones showed entire absence of the long process of the incus from caries.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

The ear was cleansed with a middle-ear syringe and a saturated solution of boracic acid in 95 per cent. alcohol injected into the attic. This treatment was carried out for the next month, at first daily, later at longer intervals, until at the end of the fourth week the ear was absolutely dry. This was in January of the present year, and the patient has been seen several times since, but there has never been a trace of moisture or crust formation. The headache and vertigo entirely disappeared, and the hearing was increased from absolute inability to hear voices so that the patient could easily understand a conversational voice at a distance of four feet.

Case 2.—*This represents a class not infrequently seen by aurists, and is by no means an extreme type.*

The patient was a man of about 40, who, during an attack of grip, developed a pneumonic condition. There was a sharp chill, with a temperature of 102, and for some days the fever was intermittent. There was severe pain in and around the right ear. As there was a history of former abscess in this ear, the family physician thought it wise to have it examined, and I was called at the end of the first week. Examination of the right ear showed a purulent discharge through a small round hole in the drum, but no swelling of the membrane or canal walls. There was marked tenderness of the mastoid and also of the back of the neck along the spine. There was dulness of the base of both lungs, more extensive on the left. The patient was unconscious, had divergent strabismus, and at times Cheyne-Stokes respiration. A diagnosis of purulent meningitis with septic pneumonia was made, and the family told that the case was hopeless. His general condition was such that he would not have survived an operation. He died within the next twenty-four hours.

Case 3.—While perhaps not so common a case, this one is still extremely instructive as an example of the condition which may follow a suppurative ear.

The patient was a boy of 9, who had had a chronic abscess in the right ear for six years. He had received some treatment for this, but for several years it had been neglected because it had not given rise to any trouble. Four days before I saw him he had severe pain shooting into the right side of the head, followed by two chills. His temperature rose to 103 at this time, he had nausea and vomiting, and was dizzy on raising his head. The pulse was very rapid and intermittent. This condition continued up to the time I saw him. Examination of the right ear showed great swelling of canal, which was filled with pus and desquamative masses. The drum membrane could not be made out. There was decided tenderness over the mastoid antrum. The heart, lungs and abdomen were negative. The boy was at once sent into the Massachusetts Charitable Eye and Ear Infirmary, and I append a portion of the hospital records:

"Feb. 8, 1903. Operation, ether, Dr. Hammond. Usual incision, cortex showed osteitis in mastoid fossa. Cortex soft, opened with hand gouge. Cells diploetic. Pus welled out. Antrum enlarged, tegmen found carious and granulations on dura, which were removed. Small opening made with chisel above linea temporalis into middle fossa. Dura normal. Posterior wall of auditory canal removed, and mastoid antrum, tympanum and canal thrown into one large cavity. Membranous canal slit posteriorly and stitched back. Whole wound and meatus packed with iodoform gauze."

For nearly a week following the operation the boy was in very fair condition, except that the temperature remained around 103. On February 14, six days after the operation, there was a temporary relapse, the temperature rising to 105, pulse irregular and some cyanosis. On the following day the patient was quite bright and improvement was marked until March 3, seventeen days later, when he suddenly became delirious. This attack also lasted but a few hours.

During the next two weeks a steady gain was made apparently. The appetite became good, he began to sit up, first in bed, then with his clothes on, and played around the ward with as much zest as any of the children.

March 18, six weeks after the first illness, there was a sudden attack of vomiting, accompanied by marked cyanosis. This was at 2 a. m. At 6:30 a. m. Cheyne-Stokes respiration was noticed. There was nausea with considerable retching, lateral nystagmus, tremor of arms and hands and convulsive movements of the facial muscles. The patient was unconscious, and at times delirious. The pupils were widely dilated, but at times reacted to light.

After consultation with Dr. J. Orne Green further operation was decided on as the only hope of saving the boy's life. I quote again from the records:

"March 18, 1903. Operation, ether, Dr. Hammond; old wound opened and granulations curetted out. Dura exposed in last operation dark and covered with granulations. Part of squamous bone removed and temporal lobe probed. A sinus extending from the base of the brain upward into the temporal lobe for two inches was disclosed. There was no pus in this cavity, but the surrounding brain tissue was necrotic. The patient did not recover consciousness after the operation, but died early the following morning. Permission for autopsy could not be obtained."

The obvious lesson to be learned from these cases is the necessity for promptly checking all suppurative processes in the ear. It is not enough that the external discharge shall have ceased, as it is possible for the disease to remain latent for years. There must be absolute cessation of crust formation before we can consider the ear well. A little careful study of cases of long standing will usually show as the cause of the chronicity some disease of the bone. After some practice with the fine silver probes used for this purpose it is astonishing how often we will be enabled to detect the presence of caries of the ossicles and even to tell with considerable precision its exact location.

As to the removal of the bones when diseased, it is merely the application of general surgical procedures to the ear. The one factor that has done as much as anything to bring the operation into disrepute is that in cases of long standing the caries may not be limited to the ossicles, but may have extended to the main temporal bone. Even in this event, although suppuration may not entirely cease, it will, at least, have free drainage, and there will be a better opportunity for the application of remedial measures.

The question of the resultant hearing in the affected ear is one of great importance to the patient, for not infrequently this is the immediate cause which leads him to seek advice. It is interesting in this connection to note that in many cases the incus is so affected by necrosis that it no longer articulates with the stapes, and, therefore, the external portion of the sound conducting mechanism (the drum, malleus and incus) is merely a hindrance to audition. A large percentage of the cases seen by the writer have shown improved hearing as a result of the operation. It is advisable, however, to always impress on the patient the importance of the fact that hearing is of secondary consideration as compared with the danger to which the necrotic lesion within the temporal bone subjects him.

Where the disease has invaded the antrum, and the discharge persists despite all attempts at its relief, the writer thoroughly believes in the value of the radical operation. By throwing open all the accessory cavities every portion of the ear becomes readily accessible, and in this way only can we be sure that there is no fistula leading to the meninges or lateral sinus. It is extremely important that all suspicious openings be explored. I recall an instance a few years ago where on probing the tegmen the instrument suddenly passed upward, opening into a large extradural abscess. The patient made a good recovery, which she probably would not have done had not this careful examination of the bone been made.

The extent of the destruction that this disease can accomplish within the temporal bone with no other symptoms than the presence of the discharge is truly wonderful. In many cases it is not until the patient has a chill, or perhaps severe pain in the ear, accompanied by serious brain symptoms, that he is brought to our attention.

Undoubtedly, most of the cases of extensive caries can be cured by means of the removal of the diseased bone and the invagination of the outer epidermis, provided the patient be brought to us while the disease is still confined to the ear. The great trouble is that these cases are especially apt to be neglected because the process is painless, and has perhaps already existed so many years that the patient has become quite accustomed to it.

It is a duty we owe our patients to inform them of the serious results attendant on neglect of this disease and to urge that advantage be taken of any measures which promise relief.

## DISCUSSION.

Dr. H. Dupuy, New Orleans—We have been taught that septic infections do not follow simple suppurative conditions in the middle ear unless the sinus be involved. Case 2, in which the middle ear suppuration was followed by pneumonia and in which there was no sinus involvement, shows that pyemia may result from middle ear suppuration without involvement of the sinus. That seems to me an important point. We can have septic infections without sinus involvement.

Dr. Frank W. Hilscher, Spokane, Wash.—Dr. Hammond spoke of a case not being cured until pus is absent. I suppose he means by that, until he can ascertain no longer the presence of pus.

Dr. Hammond—The case must be followed until there is absolute dryness and absolutely no pus formation.

Dr. Hilscher—In a case that gave me a great deal of trouble in diagnosis there occurred absolute dryness and no local evidences of pus formation, while there was great destruction going on behind an intact drumhead. The patient, a farmer, was supposed to be suffering from typhoid fever, and was in the hospital a little over a month before I saw him. The physician in attendance asked me to see him because of a discharge from his left ear which had begun the previous day. I found a little pus running from the auditory canal. On examining the temperature chart I found it was not the usual curve typical of typhoid fever. Subnormal temperature, followed by a sudden rise of temperature frequently occurring during the last few days, made me suspicious of sinus involvement. He had no tenderness whatever over the mastoid and had had none at any time. I was at a loss to make out any mastoid trouble. I treated him in the usual way I do suppurative ear cases, and the next day I found the membrana tympani closed up and the ear absolutely dry. I watched him for several days and still there was no pus in the cavity. Subsequently I opened the mastoid and found a large cavity filled with pus, the inner wall perforated and a thrombosis of the lateral sinus, thus giving entrance of pus to the blood and producing pyemia. I mention the case to call attention to the difficulty in diagnosis occasionally met, and the ease with which mastoid disease may be and is frequently overlooked and death ascribed to other causes.

Dr. J. F. Barnhill, Indianapolis—Otologists should never neglect an opportunity to warn the profession and laity of the danger that lurks in a discharging ear. I have been convinced, as you no doubt all have been, that we have not been careful enough to explain to patients the nature of these dangers. We have not been as careful as have the abdominal and general surgeons. A few years ago, for instance, in the discussion of appendicitis, the most aggressive abdominal specialists of this country took pains to warn the public as to the dangers of this disease. The art of oratory was freely indulged in, and one gentleman stated that if a red light were hung on every grave filled by a victim of appendicitis, the world would be lighted by night. There is as great danger from a chronic discharging ear as there is from an appendix in which there is pus formation, but too many of the profession do not as yet recognize this fact. Many an individual with such a discharging ear walks the street or goes about his daily work, who, could he know the danger, would seek his physician immediately. McEwen, in his book, says that such a patient may work at the severest labor up to the very hour of the rupture of an otitic abscess. There is so often but little pain or other disturbance from aural discharge, and the patient has had ear trouble so long without anything alarming befalling him, that he may go on entirely unaware of his impending danger until the end is already reached, and the operator, if given a chance, has not the certainty of results that would have been assured by earlier surgery.

Dr. C. M. Cobb, Boston—Sometimes these patients die in a few hours, but if we can save even one life we have done a great deal. I saw a patient whose family physician had seen him at 3 o'clock in the afternoon. The patient was provoked that the physician had been called, and he declared that he was not sick. He died at 1 o'clock the next morning. He had an old ear disease, which gave him so little trouble that his wife, who had been married to him five years, did not know he had it. That was an extremely rapid case. I have seen cases with convulsions, and practically all of them have had meningitis. They usually know for a long time that they have trouble with the ear and become accustomed to it, and do not know that it is a menace to life.

Dr. George L. Richards, Fall River, Mass.—I have had a number of experiences which prove the extreme danger of suppurative inflammations of the middle ear. I saw a case in the hospital; the patient went home, but the next day he was brought back hemiplegic and comatose and, although operated on, he did not recover. Often these cases do not come under observation soon enough. We should state to these patients that we can not accept the responsibility of chronic suppurative inflammations of the middle ear unless they are properly treated. There is so little pain in these cases and they often last so long with so little discomfort that the patient disappears from our observation if we do not cure the discharge in a little while. We should state to them that every one of these cases is a slumbering volcano liable to erupt at any time.

Dr. Philip Hammond, Boston—It seemed to me that one of the most interesting features in the last case, in which there was necrosis of the brain tissue, was that, although this boy was under the observation of trained assistants, no definite symptoms were observed. During the last two weeks of his life there were absolutely no definite symptoms of this trouble in the brain. I have seen fatal cases following direct extension of the suppuration through the tegmen. I remember during one week in the hospital two cases died in that way. In one case we had an autopsy, and in the other we know there was a sinus thrombosis. Dr. Hilscher spoke of the operation on the sinus. In chronic suppuration with caries of the temporal bone it is common not to have tenderness of the mastoid.

---

**A Layman's Interest in Anatomy.**—It is related that Dr. Nuhn, the professor of anatomy, at Heidelberg, was much surprised one day when a banker, usually unsociable, sat with him in a railway car, and, after a pleasant chat, asked him all sorts of questions, especially about the anatomy of the heart. The next day he called, by permission, and watched the professor dissecting one of these organs. Then he drove home, and a few hours later it became known that he had committed suicide by skilfully plunging a dagger into his heart.—*Medical News.*

# THE EFFICACY OF THE TREATMENT OF ACUTE PURULENT OTITIS BY ASEPTIC DRAINAGE.*

H. GRADLE, M.D.
CHICAGO.

The object of this paper is to show the superiority of the treatment of acute purulent otitis by aseptic drainage. The method itself is the familiar one which has gradually gained in popularity. Its principles are paracentesis as soon as the diagnosis is made, and continuous absorption of the discharge by an aseptic gauze drain in the meatus and a large dressing over the auricle. After sterilization of the meatus and auricle by means of carbolic acid solution the sterility of the gauze is further assured by the liberal use of powdered boric acid in the dressing. The external gauze pad is changed as soon as moisture shows, while the tampon in the meatus may be left 24 to 48 hours at a time.

Notwithstanding its simplicity and efficacy, the superiority of this treatment is not universally acknowledged. In illustration I might quote two recent publications by acknowledged authorities. Politzer, in the latest edition of his text-book, does not wish to exclude syringing and other methods completely and speaks of the "dry treatment," but in terms of qualified praise. Bezold[1] prefers syringing, mopping and boric acid insufflation because he has seen unsatisfactory prolongation of the discharge and frequent complications in the form of mastoiditis in consequence of the dry treatment. As I shall attempt to show, such unfavorable opinions must have been based on imperfect technic.

What criterion are we to apply in judging of the efficacy of any treatment of purulent otitis? The duration of the disease and its severity are so variable that statistics as to time of recovery are not fully convincing. Even in cases of similar etiology the time of recovery varies with the individual's power of resistance. A valuable contribution to the point is, however, a table presented at the last meeting of the German Otological Society by Koerner. Among 78 cases the time required for healing was 7 days after paracentesis done on the first day; 9 days after paracentesis done on the second day, and up to 26 days after paracentesis done on the seventh day or later. From personal experience I can say that whenever the "dry" treatment was carried out rigidly the course was shorter by at least one-third than I would have expected formerly in cases of similar severity.

The criterion which I have learned to regard as a proof of efficient treatment is the character of the discharge. In the milder cases, which either perforate spontaneously or are punctured within the first or second day, the discharge is always entirely serous and neither stringy nor purulent. I believe that the same rule applies to all cases of acute otitis, no matter how severe, provided the drumhead is punctured early enough. It is true a perforation or a paracentesis done after the third day usually yields a purulent discharge. But whenever I have had the opportunity to tap the drumhead earlier than 48 hours after the onset I have always obtained a clear fluid. By means of a properly absorbing gauze dressing reaching to the drumhead and changed sufficiently often to remain absorbing and sterile this serous discharge can be kept serous. Its change to a purulent fluid is due to faulty technic. No other treatment with which I am familiar prevents the discharge from becoming purulent except in the mildest cases.

My invariable experience has been that after a climax in the amount of discharge within the first 36 to 48 hours the secretion diminished steadily and progressively to an uneventful recovery, provided due care was taken to keep it serous. The length of time of the discharge in some 40 cases in which the method was carried out successfully varied from 5 to 12 days in the majority, and but exceptionally ran to 15 days. If through any neglect the discharge becomes purulent this progressive improvement is interrupted as indicated by unchanging rate of secretion, and hence longer duration, greater discomfort and the possibility of mastoid complication.

The change from a serous to a purulent or mucopurulent secretion seems to depend mainly on insufficient removal of the fluid. Hence a late spontaneous or operative perforation yields pus at once. If the drainage is not perfect by reason of some neglect the unfavorable change in the character of the fluid will take place speedily. Secondary infection through the meatus with other bacteria may also occur later on and prolong the disease. But during the earlier period this does not seem to be common.

The treatment by aseptic drainage requires, therefore, skillful supervision in order to be successful. But when successfully carried out it has yielded, in my observation, the quickest result and the mildest course. In no case have I ever seen any complication as long as I succeeded in keeping the discharge serous.

In the case of a purulent discharge due to a late perforation or insufficient care in the change of the dressing I have found gauze drainage as satisfactory as any other mode of treatment. But since thick pus is not absorbed as freely as a serous fluid the special superiority of the treatment is not as apparent as in those instances in which its early and proper use prevented purulency of the discharge throughout the entire course.

# THE GREAT VALUE OF DRAINAGE AND ICE IN THE EARLY STAGES OF MASTOIDITIS.*

SARGENT F. SNOW, M.D.
SYRACUSE, N. Y.

At the last session of this Section I presented a paper[1] on "Conservatism in Mastoiditis," in which 40 well-developed, advanced and some serious cases recently treated by free tympanic drainage and the use of ice over the mastoid without a failure were reported; the observation was also made that I believed over 50 per cent. of our present external operations could be avoided. The paper was followed by a spirited discussion during which many valuable points were brought out and some criticisms on my position were offered, but experience impels me to remain of the same, or a stronger, opinion. It also became manifest by the discussion that otologists do not yet agree as to the best course to pursue in treating the purely acute forms of this disease.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

[1] The Journal A. M. A., Jan 31, 1903.

That conservatism has a place in acute mastoiditis is clear, but I emphatically desire it to be understood this year, as well as last, that I take a conservative attitude only as compared with those who advise the external operation immediately on evidence of mastoid involvement, and then under the following conditions:

1. Conservatism must be confined to cases not complicated by extreme or intercranial symptoms.
2. Free drainage must be secured promptly by a skilled otologist and this followed by conscientious trained nursing.
3. The patient must be kept within easy reach and treatment continued for a few days after active symptoms have subsided.

In those cases where the above conditions can be complied with conservatism becomes a safe, and may form a very proper, subject for consideration, even by this body of men, skilled as they are in more radical surgery of these parts, but cases presenting symptoms of intercranial involvement or extreme conditions, even in acute mastoiditis, require such free drainage as can only be obtained by the external operation.

From a twelve years' experience in mastoid cases, in which hundreds have been under observation, it appears to me that in any line of treatment short of operating externally free internal drainage secured in the early stages is all-important. This should be accomplished by what may be termed a tympano-Wilde's or tympano-canal operation, cutting the drum in the posterior half from the lower border upward, to and through the attic folds, outward along the internal mastoid or superior posterior wall of the external auditory canal. Such an incision is done by a spear-shaped double-edged knife strong enough to lay the tissues open to the bone, thereby lessening periosteal tension in the immediate region of the inflammation, as well as giving free drainage from the tympanum and attic. A momentary anesthesia produced by gas, bromid of ethyl, or chloroform is necessary in aggravated cases, for we must be exact and thorough. Of the three I prefer bromid of ethyl, but chloroform is also very satisfactory.

Before this operation in acute otitis media we have a cavity containing secretions often most virulent, the active agents of which are sure to invade deeper structures; after it we have a simple abscess properly drained. Pent-up secretions will seek the point of least resistance for an outlet; if the drum membrane does not give way the mastoid naturally and easily becomes involved. What could tell us more plainly that our first duty is to secure a proper outlet for this menacing accumulation?

Some drumheads are very tough, and we can not assume that they will yield to pressure before the mastoid cells are put in hazard. Even if they do yield the opening is liable to be insufficient to care for the large amount of pus that is being manufactured, and mastoid symptoms begin to develop, voicing Nature's demand for better drainage. Verily, he who obtains and maintains a free drainage in acute otitis media averts a probable mastoiditis.

An active inflammation of the middle ear is really the first stage of mastoid trouble; prevention in this early stage is worth a pound of cure later; while in some cases a simple puncture of the drum may be all that is necessary to abort more grave conditions, it seems better to be on the safe side and make the incision free and deep. Why should we hesitate? No damage to the hearing comes, for repair sets in only too quickly, often forcing us to enlarge our original opening to keep a proper pus outlet.

When there is an actual involvement of the mastoid cells, the free incision above described, whether an external operation appears probable or not, is imperatively demanded. It is a rational procedure, even if only done for temporary relief in the interval that commonly exists between our first examination of the case and the time set for the external operation, and as in two of the cases cited in my previous paper,[1] will sometimes, even in profound cases, make the more radical work unnecessary.

Antiphlogistic measures are supplementary to drainage, but serve as a great aid in controlling pus formation and inflammatory action. In those cases characterized by much pain and pushing forward the auricle from cellular inflammation in the soft tissues about the canal, hot injections and fomentations afford much relief; in fact, irrigating the ear with a quart of water at 115 degrees F. every 20 minutes is a most excellent treatment in such swollen conditions and serviceable in reducing pain in any stage, but as soon as relief is obtained, the application of constant cold seems to the reader more reliable for routine treatment. The temperature should be recorded every three hours to make plain sudden variations; in no event does it appear good policy to mask symptoms by opiates.

The Sprague ice bag kept properly filled and put on so that it is maintained in immediate contact with the skin over the mastoid is without question a most excellent antiphlogistic.

As I have mentioned in previous articles and in discussions at each opportunity during the past seven years,[2] ice applications, to be effective, should be constant, continuous and prolonged. There should be no marked intervals in the renewing, as often happens in our hospitals when the nurse takes the bag to refill but is interrupted by a call from another patient to which she attends before the ice is reapplied. Such an interruption in treatment may not occur more than twice in twenty-four hours, but unless we have been very specific in our directions this or some other lapse is apt to occur many times, and what is the effect? The parts at once begin to warm up, blood vessels to dilate and pus elements to multiply. If through an improved condition our drainage incision has partially healed, the opening will now prove too small, secretions will again become pent up, pain, tenderness over mastoid, swelling and temperature will increase, and we have to begin over again, for perfect drainage must be maintained. Under careless, haphazard conditions ice may not seem to do much good and I doubt if it does, but the fault does not lie in the principles of treatment; proper nursing would have brought the expected good results.

Ice applications are also serviceable to retard inflammatory activity until the surgeon can arrive and, if continued two or three days after the pain, tenderness and temperature have subsided, practically prevent relapses, though the patient is still human and may take a cold, but will again be amenable to treatment.

Personally, I often keep the parts under this constant low temperature until the discharge ceases, which in several severe cases has been accomplished in six days. In no case except one with tertiary syphilitic trouble has there been a relapse nor in any case a permanent loss of hearing.

[2] See Transactions of the American Laryngological, Rhinological and Otological Society, 1898, p. 72; 1901, p. 208, THE JOURNAL A. M. A., 1899.

In a broad way we can safely assume that if the case is in an acute uncomplicated state when it comes under the care of the specialist he should be able to handle it without being forced to operate externally. Exceptions to this rule are possible and very proper if the symptoms be severe, and the patient will have to be left far removed from operative facilities, or if the required environments and nursing can not be secured.

Prolonged, subacute and chronic cases, or those giving a history of previous otorrhea, are liable to be accompanied by osseous changes, complicating conditions to the extent that unless the otologist is brought into the case early external operating becomes the wisest plan. On the other hand, acute cases without evidence of central involvement—acute cases having very pronounced local symptoms, located within easy reach and under good care—can be given more latitude. Infected lymphatic tissues about the external canal give startling external appearances without a real involvement of the cells. The fact that we have a tender mastoid, projecting auricle, prolapsed superior wall, high temperature and profuse discharge need not tell us to proceed immediately with the external operation; but it does tell us that we must at once improve the drainage and combat the inflammatory action. The argument that the facility with which the external operation, under mallet, chisel and curette, can be done on the usual skull, justifies us in securing drainage that way, loses weight when compared with the short anesthesia, slight shock, danger and expense of the internal operation.

In all those cases that come to the specialist late, with well-advanced to severe states, conservative plans of procedure must be followed by prompt improvement, and no plan should be instituted that is not aggressive and thorough as above outlined. In these acute but advanced cases a marked change for the better must occur at the end of thirty-six hours or external drainage should be secured; it ought to come within twenty-four hours if we have obtained proper drainage by the internal incision and the nursing has been up to requirements. Under no circumstance can an indifferent waiting plan be sanctioned; ultraconservatism is little less than criminal. A better education of the general practitioners on the importance of getting mastoid cases under skilled hands in the early stages is our privileged obligation, and we all can well unite in such a campaign. The possibilities of influence over mortality seems unlimited.

In conclusion, I would say: 1, A conscientious observation of my cases has impressed me with the great advantage we at once obtain over the disease if we secure such free drainage from the middle ear and attic that a tympano-canal incision will give; 2, while many cases will get well simply because we secure proper drainage, the constant and continual application of ice does much to reduce morbid activity and hasten recovery.

I recommend with great confidence the treatment herein outlined, and I believe that when once it is thoroughly tried your commendation and enthusiasm will equal my own.

## DISCUSSION

### ON THE PAPERS OF DRS. GRADLE AND SNOW.

**Dr. J. F. Barnhill**, Indianapolis—I am a believer in the efficacy of aural drainage by dry treatment after the method Dr. Gradle has outlined, and I think that in such treatment we can in many instances cut short acute aural diseases, save hearing power and prevent possibilities of mastoiditis. One thing that ought to receive most careful attention from the otologist, before the paracentesis is made, is to have not only the knife and the hands of the operator aseptic, but also a careful cleansing of the external auditory meatus. The object of the operation is to secure drainage without infection from the outside, and if the external meatus is not thoroughly cleansed, suppuration is almost sure to follow. Hence my practice, before making a paracentesis, is not only to syringe the external meatus, but also to rub hydrogen peroxid into the hair follicles and the adjacent skin, to wash this away, and later mop with alcohol. After the paracentesis has been thoroughly done, I believe it is best not to wash the ear but to pack immediately with sterile strips of gauze. Unless the aurist is able to see the patient frequently, it is best to place a large piece of gauze over the external ear and hold this there by a roller bandage. Such a dressing as this may be left on twenty-four hours, and then it is not always necessary to change the strip which has been placed in the external meatus. The patient or his attendants should never be permitted to change this latter strip unless they have been thoroughly trained as to the aseptic method of doing it. If Dr. Gradle's method is carried out and the patient is seen often enough, it will certainly prevent that continuance of the discharge which too often follows rupture of paracentesis of the drum membrane. I concur in much that Dr. Snow said, but must we not often ask ourselves the question, does conservatism mean waiting in every case, and does it not sometimes mean early surgery? After we have secured the best drainage possible through the external meatus, and the pain still continues in and around the ear, we are not conservative if we wait long before doing a radical procedure. It seems to me probable that few otologists, if any, have sufficient experience in diagnosis to tell how far suppurative disease in the middle ear may have advanced. The depth at which the disease lies prohibits certainty of knowledge in many cases. The amount of discharge, the severity of pain or the absence or presence of fever can not indicate definitely what may be going on in the depths of the ear or the mastoid process. I have often opened mastoids when the patient had previously complained of little pain, there had been no fever, and yet the mastoid cells contained pus. In such cases it can not be conservatism to wait. In at least two cases I have felt that by conservatism I have lost the patient. By an operation done a few hours before death, I have been taught that conservatism is sometimes on the other side. Only a month or two ago I lost a case by meningitis in which if I had operated I would have saved my patient. But the patient's friends' conservatism lost me my patient. In that case there was nothing but a discharge from the ear, no pain and no fever. I feel that one of the greatest things done by a mastoid operation is to save the hearing of the patient. Probably you often have seen a patient with such a flow of pus from the ear that you could with difficulty keep it removed. You know the discharge comes not only from the middle ear, but also from the mastoid antrum and adjoining cells, and that it has found exit through the middle ear because this is the weakest point of its environment. Damage is done to the middle ear by the continual passage of this pus through its cavity, and if no other outlet be provided, and the disease allowed to become chronic, the tissues of the middle ear remain inflamed and thickened, adhesions are apt to occur, and a considerable loss of hearing power will be the inevitable result. In such a case if a mastoid operation be made early and the pus allowed to drain through the mastoid wound, the middle ear becomes dry in a remarkably short time, its structures are saved from deformity or destruction and the hearing power is well preserved.

**Dr. Samuel L. Ledbetter**, Birmingham, Ala.—In these acute conditions of middle-ear disease the results depend largely on the cause of the inflammation. In the spring of 1902, during an epidemic of middle-ear troubles from la grippe, sometimes the discharge would remain serous ten days or two weeks before it would change its character, and some cases would recover without the discharge becoming purulent at all. The engorgement was in all cases intense. All recovered without mastoid operation. Cases of intense middle-ear congestion will sometimes be relieved by ice applications, thereby preventing mastoid complication. I do not think it is best to wait for mastoid symptoms before using ice. As to preventing sepsis, I have seen cases that were treated most carefully become purulent in a short time. In others, where the drum had ruptured with no preliminary cleansing, recovery would sometimes occur without pus.

DR. EDWARD J. BROWN, Minneapolis—We agree that drainage is the important factor in these cases. In a discussion of this question two or three years ago a physician whose name I do not recall stated that in his practice he had displaced ice and hot fomentations by carbolic glycerin. I have since used the 10 per cent. carbolic glycerin instead of gauze in pus cases with great satisfaction. Cleanse the ear carefully, dry it, fill for five minutes with 1 to 1,000 bichlorid, then with the carbolic glycerin, ordering the latter renewed every hour or two, with use of absorbent cotton. I have used this carbolic glycerin constantly since 1889, when it was recommended by Arthur Hartmann, in his treatise on the ear, as a hot application for the relief of pain of acute otitis media.

DR. PHILIP HAMMOND, Boston—There are various factors that determine the way these cases will turn out. Much depends on the bacterial invasion of the mastoid cells, and of even greater importance is the arrangement of the cells. Experience shows that a diploetic arrangement of the mastoid cells gives rise to more serious troubles than any other kind. There are cases in which there is pus in the mastoid and even cases where the pus escapes down the mastoid muscle, in which the pus is absorbed. I have seen such a case, treated by a physician who might be called "conservative," in which the patient was left alone and the pus was finally absorbed. Another question is as to when the mastoid is infected. I believe it is infected from the very start. I have seen the mastoid opened early and I have never seen a case in which there was not infection as ascertained by culture, when this was made. In one case in which there was mastoid tenderness that had apparently subsided, there was later a chill, and the patient died despite an operation made at that time. Such cases lead us to be more radical rather than so-called "conservative." I wish to commend Dr. Snow's reference to the use of heat and cold in the treatment of the very early stages.

DR. GEORGE L. RICHARDS, Fall River, Mass.—While I recognize the absolute earnestness of Dr. Snow's purpose, I think there should be a word of warning. I know of a case in which there was a free incision of the drum membrane followed by the application of ice. The trouble apparently subsided and the patient went home. The next day there was a return of the trouble and an operation showed the bone broken down. The superficial cells were involved and the antrum had drained out. The ice had masked the infection of the superficial cells. In spite of every effort the patient died. Although I believe in very early incision and the use of ice during the first few hours, this treatment is not sufficient later in the disease. If one can not get good gauze drainage, it is better to syringe every hour or two with 1 to 2,000 or 3,000 or 4,000 bichlorid. I think ice should be abandoned after 48 hours. After one loses a case by over-conservatism he is willing to open the mastoid in every such case. The operation does not endanger life, and it would be safer to operate unnecessarily forty times than to lose a case from so-called "conservatism." Dr. Gradle speaks of putting a bandage over the ear. You can accomplish the same purpose by giving the attendant of the patient a number of pledgets of gauze or cotton and directing that they be placed next to the gauze wick and changed as often as they become moist.

DR. C. M. COBB, Boston—It does very well to be conservative, but I am absolutely certain that I have no means of knowing what is going on in there. If the discharge of pus or other symptoms continue, I feel there is pus under pressure, and possibly necrosis is taking place. The patient either lives or dies under "conservative" treatment without any reference whatever to the treatment after the first few days. Hundreds of those cases get well, regardless of the treatment employed, but I doubt if the ice after the first four or five days has any influence whatever.

DR. FRANK W. HILSCHER, Spokane, Wash.—I have been in the habit, in these cases, of stimulating the secretions and excretions by calomel and some aconite, belladonna, and small doses of opium. I fancy I have had good results from these measures in connection with other things mentioned. I therefore think that constitutional treatment should not be overlooked.

DR. D. A. KUYK, Richmond, Va.—I would like to report a case regarding the "conservatism" that has been mentioned. A little girl who had had scarlet fever about six weeks prior to my visit was suffering with middle-ear trouble. The physician in charge made ice and hot water applications. After over two weeks of this treatment I was called to see the case. I found the ear bulged out by a swelling over the mastoid. Three days later I operated and found five or six tablespoonfuls of pus and the whole mastoid a mass of disintegrated bone. When I left, the next night, the child was doing very well and had no temperature. If our "conservatism" had not been carried so far in that case the child would not have had to undergo so long a stage of convalescence.

DR. JOHN A. DONOVAN, Butte, Mont.—Following the advice Dr. Dench gives regarding the dangers of ice, and from some experience I have had, I consider ice absolutely dangerous, as a rule, after the first twenty-four to forty-eight hours. From the fact that I have recently lost two patients from late operation, I am considerably in favor of early operation in these cases. But some of these patients will not be operated on and many of them recover without any external applications.

DR. MAURY M. STAPLER, Macon, Ga.—I have had two cases with tenderness over the mastoid and involvement of the ear in acute inflammation. The drum membrane was intact. In these cases I used, instead of ice, adrenalin chlorid 1 to 1,000, applied in the canal and over the mastoid. I repeated the application for about two minutes, six times a day. That treatment was continued for two days, and both cases recovered. I can not say as to the relative value of the method.

DR. H. GRADLE, Chicago—It is pleasing to find most of the speakers in agreement with me. Still good authorities, especially European, are not so universally in favor of the "dry" method, and now and then we find articles in American literature referring to other methods of treatment that I must consider inferior. The course of an otitis depends on whether it is a staphylococcus or pneumococcus infection; and, secondly, on whether it is an idiopathic coryza, an influenza coryza or scarlet fever or some other condition which leads to the infection. Nevertheless, if we make it a habit to operate early, inside of twenty-four hours after the trouble begins, we can, with due care, keep a serous discharge serous, as a rule, and the cases will then be more uniform and less severe. Practically, we often see our patients only after perforation has taken place or only after several days of pain when we are compelled to perforate late. After pus has begun to form drainage by gauze alone is not so successful. Often it is better to syringe such cases. The pus is so stringy that drainage by gauze alone is not always sufficient. I can remember a case in German literature in which the patient died of a cerebral complication, in which the discharge was only serous. But personally I have not seen any complications in cases with a serous discharge. Where I can not see the patient often enough I have come to trust more to saturating the gauze in the ear with nitrate of silver solution (2 per cent.) for antisepsis. The external gauze I powder freely with boracic acid. Of course, the external auditory canal is sterilized as much as we are able to with carbolic acid. I believe sublimate solution is untrustworthy. I have the external ear dressed with gauze or cotton, preferably gauze, and it is changed as often as necessary. Dr. Snow's paper very well contends against unnecessary operations, but less conversant practitioners might err in carrying conservatism too far. Many doubtful cases recover without mastoid operation, but the risk they run is much greater than if we operate early. When there is only tenderness and possibly slight edema it is not necessary to operate in the first twenty-four or thirty-six hours. But if this continues longer than twenty-four or thirty-six hours "conservatism" should be abandoned. The thicker and the more profuse the discharge from the middle ear the more should we favor an early operation on the mastoid. I would consider the operation indicated even when the external symptoms, such as pain, are wanting, in case the discharge from the ear does not diminish gradually in the course of some ten or twelve days under efficient treatment. since such cases are likely to become chronic.

Dr. Sargent F. Snow, Syracuse, N. Y.—I have tried to make my position plain in this matter. I do not believe in ultra-conservatism. I do not believe in taking chances in subacute or chronic cases. I do not believe in taking chances in acute cases if we have extreme symptoms. But if it seems safe I advocate free drainage and the application of ice until we can see what is going to develop. If we do not get a prompt abatement of symptoms, we should operate promptly. We must not take chances. I kept the ice on from four to six days in cases that at once began to show improvement after the free incisions and I kept the ice on to continue the improvement. If we keep the mastoid tissue at such a low temperature, as we can safely, we certainly prevent morbid activity. The point made by Dr. Cobb about continuing conservatism too long is certainly most excellently taken. We must not continue conservatism too long. If the symptoms commence to rise again, we must at once find the cause. If there is retention of pus, we must relieve it at once. Then as to the safety of continuing the ice six or seven days; it is safe if the patient is making an uninterrupted recovery. In my experience the continuous application of cold does favor a complete resolution of the trouble. I do not advise it for any length of time. I have kept it on five or six days. In those cases where I took it off earlier I found the discharge increased and I had to enlarge the outlet or put on ice again. Then as to the influence of conservative recommendation on the general practitioner, I was afraid of that, myself, last year, and I have watched the effect of last year's paper with a great deal of interest. Since the paper has come out and the reprints have been distributed the number of practitioners who have sent me cases in the early stage has markedly increased. I have tried to emphasize the point that they must get the cases under skilled hands early. The diploetic mastoid is in that state in which it is unsafe to place much reliance on conservative efforts. I am very careful, in all the cases of chronic otorrhea that develop acute symptoms, to operate externally. The internal operation is applicable only when done very early.

---

# DIABETES MELLITUS;

## THE LIMITATIONS OF ITS DIETETIC TREATMENT.*

ARTHUR R. ELLIOTT, M.D.
Professor of Medicine, Post-Graduate Medical School.
CHICAGO.

Over 100 years ago Rollo pointed out the supreme importance of diet in diabetes, and demonstrated that by restriction of the carbohydrate principles of food sugar could be made to disappear from the urine and a general improvement in the patient's nutrition result. In elaboration of this principle, Bouchardat laid down in their minutest details the rules of the dietetic regimen, and ever since, and until a very recent date, discussion has only been on points of minor importance, such as the eligibility of certain foods or beverages for introduction into the various dietaries, strict or moderate. This, our most valuable means of combating the diabetic dystrophy, was conceived in empiricism, and, until comparatively recent times, was practiced empirically, the only guide being the results obtained—the fluctuations of the glycosuria and the state of the patient's general well-being. It may be said that these indications, to a large extent, still govern our procedure, but, thanks to the work of Von Noorden, Rubner, Hutchinson and Atwater, we are now able to base our dietetic prescriptions on a physiologic foundation. The scientific justification of the dietetic treatment of diabetes may be said to be established beyond question, and the details of procedure have been well elaborated; still, to the profession at large, much is wanting in a proper understanding of its principles, and more especially its limitations.

I think it may, without prejudice, be maintained that we have not yet reached the point where we may hope, by means of any at present known remedy or combination of methods, to cure the disease. The diabetic dystrophy is too deep-seated and involves too intimately and seriously the intra-organic nutritive processes for us to hope to correct the perversion by the exhibition of drugs, or to in any way effect more than palliative results.

One result of this symptomatic treatment, to which our disappointment in attempts at specific medication has forced us, is that we have come to attach too much importance to the glycosuria and, forgetful of the fact that this is but one, and by no means the most important, manifestation of the disease, we have bent our energies toward suppressing the excretion of sugar, without full regard for the welfare of the patient in other respects. It is absolutely necessary at the outset to realize that the glycosuria *per se* is capable of little harm; that it is the systemic condition of which glycosuria is but the outward sign that is the threatening element, and that it is to the general nutritive state we must look for the indications which are to guide us in our treatment, and not to the amount of sugar in the urine.

It is not my wish to depreciate the value of controlling the glycosuria, but rather to emphasize the importance of looking farther for results than in the urine.

Removal of the sugar from the urine, unfortunately, does not mean cure of the disease, otherwise we would all have many recoveries to our credit. What is required for cure is a restoration of the assimilative power and improvement in general strength and well-being, and in proportion as these are brought about, we may know that we are succeeding in our treatment.

However authorities may differ regarding the pathogenesis of diabetes, the chemistry of the perversion is coming more clearly into view, and its harmful influence on systemic nutrition is better understood. As with all other nutritive diseases, we have as the essential feature of the diabetic state a hematic dyscrasia, characterized by an excess of glucose and the presence in the blood of various toxic bodies, the outcome of excessive and abnormal proteid metabolism. These factors are potent influences in bringing about deranged tissue states and are probably supplemented in that direction by defective nervous action, always a more or less prominent attendant on diabetes. These influences do not prevail to an equal degree in all cases of the disease, different cases presenting great divergence in intensity and rapidity of progress. The laboratory student would have us regard glycosuria as but syndromic, the mildest differing not in kind but merely in degree from the severest form. The clinician, on the contrary, divides his cases into two distinct classes, mild and severe, recognizing the difference between a slight controllable glycosuria with the patient but mildly ill, and the intractable and rapidly progressive disease with its invariably fatal termination. This broad clinical division, although somewhat arbitrary and lacking in specification, has become established by custom and is universally recognized by clinicians. The mild type of diabetes may be defined as an impairment of the power of the organism for assimilating the carbohydrate principles of food, so that hyperglycemia results and sugar appears in the urine. The various symptoms encountered depend for their origin on the presence of sugar in pathologic amounts in the blood. When the glycosuria is controlled by reduction of ingested carbohydrates, more or less prompt subsidence of all symptoms ensues in this form of diabetes.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

A striking contrast to this ready control is presented by the severe form of diabetes, which undergoes comparatively little abatement in severity, even after complete withdrawal of carbohydrates from the diet, sugar still appearing in the urine, showing that the sugar-splitting function of the cells is so gravely impaired that the carbohydrate moiety of the proteid molecule can not be utilized in the economy. Progressive emaciation, polyphagia and a gradually deepening toxemia characterize this form of the disease, which presents such varied and marked contrasts to the mild type as to apparently stamp it as an entirely different pathologic process.

In the severe grades of diabetes it is generally accepted that the sugar is derived from the systemic albumin as well as from the carbohydrates of the food, whereas in the light form it comes entirely from the latter source. From an etiologic point of view, the dietetic treatment should, in many respects, be different in the two forms. In the severe all that can be accomplished by the antidiabetic diet is some reduction in the amount of circulating sugar. We can not hope to suppress the glycosuria or control the dystrophy. The utmost we can accomplish by diet is to control somewhat the glycemia and toxemia, and thus, by establishing within the body a closer approach to normal, haply effect some augmentation of strength and preservation of body albumin. In the mild form of the disease, which is an affair of starch malassimilation, to control the glycosuria by adaptation of the diet is only a rational procedure, and can not be otherwise than right. The passage of sugar that can be controlled by diet means the infliction of unnecessary harm on the tissues, and this stands in proportion to the amount of sugar that escapes combustion and is carried off by the urine.

The work of physiologic chemists shows that the diabetic converts just as much potential energy into kinetic force as the healthy individual, there being no difference in this respect between them. The diabetic is handicapped in a nutritive way, however, because of the great loss of sugar, a valuable heat and energy-producing material, by the urine, a loss which must be compensated by increased destruction of body tissues. The destruction of albumin is in this manner greatly increased, and as a result we have much augmented elimination of nitrogen and the progressive loss of weight and strength, which is so noticeable a feature of diabetes. In examples of the severe grade of diabetes there usually exists along with the breaking down of body albumin a collateral formation of organic toxins of acid character, which in their turn complicate the nutritive problem by a disturbing effect on cell protoplasm. It is this tissue waste and its attending toxemia which constitute the real danger in diabetes. Were it not for this, glycosuria would be nothing more than a disagreeable symptom with no immediate dangers, but merely remote and somewhat uncertain secondary effects.

Preservation of body albumin, under all circumstances, must constitute the standard which is to guide us in our regulation of the diet, and the endeavor must be to not only maintain the strength, but, as far as possible, add to the store of bodily energy. When viewed in this light, the body weight becomes the criterion of our success, and not the amount of sugar in the urine.

Some diminution of bodily fat is an inevitable attendant on any restriction of the diet in diabetes, and this may not be wholly undesirable in obese subjects, but it can not be allowed to proceed beyond a certain limit, even in these cases, without detriment to the general health. According to Von Noorden, in order to assure the preservation of body albumin, an amount of food adapted in accordance with general physiologic laws to the needs of the economy is necessary. If the amount sinks below these needs, that is to say, below the output for the time being of the organism, the deficit must be met by a levy, not only on the fats, but also on the albumin of the body.

By reference to Von Noorden's tables we find that a man taking moderate exercise consumes nutritive material to the value of 3.5 calories per kilogram a day. In the case of a man of 70 kilograms (154 lbs.), the average of daily consumption would be represented by about 2,500 calories. The diet must be regulated so as to provide nutritive material to cover this total.

It has been estimated that in health man obtains from 40 to 50 per cent. of the total number of nutritive calories from the carbohydrate principles of food, the remainder being about equally divided betwen the fats and the proteids. In the diabetic state the system is not only deprived to a large extent of the immense nutritive benefit of the carbohydrates, but, as Pavy has pointed out, the effect of this class of food is diametrically opposite to its influence in the healthy state, for instead of contributing to the increase or maintenance of weight, it leads to decrease in weight, through stimulating waste and inducing a wrong state of the system by the abnormal presence of sugar in transit in the blood. Some substitutes must, therefore, be found to take the place of the carbohydrates, and to accomplish this one has to choose either proteids or fats. The net calorie value of various food classes has been estimated by Kleen as being for proteids, 3.2 cal.; fats, 8.4 cal., and carbohydrates, 3.8 cal. in healthy subjects, and usually as much in diabetes, minus, of course, the loss by glycosuria in the latter case.

Our ideas as to the relative value of food constituents as energy producers have undergone considerable change in the light of recent physiologic observations. It was formerly believed that proteids were the principal source of bodily energy, whereas carbohydrates and fats contributed chiefly as sources of heat. It is now known that carbohydrates and fats, as well as proteids, supply energy to the body, and that, moreover, it is a matter of indifference, so far as the ultimate result is concerned, which food is supplied to the organism, provided it be given in amount proportionate to its dynamic equivalent. Heat is a sècondary product, the result of cellular activity.

So far as these deductions carry us, the solution of the nutritive problem in diabetes would seem to consist simply of a proportionate increase in the amount of proteids and fats of the food, so as to meet the caloric demands of the organism. The necessity which we have to face, however, is not merely one of substitution for carbohydrates, but a multitude of difficulties complicate the problem. Some means must be devised to terminate the abnormal albumin breaking down, which is so frequently a result of the constitutional vice. Moreover, the digestive welfare of the patient must be duly taken into account, otherwise anorexia, disgust and dyspepsia will vitiate the good effects of our endeavors.

Proteids are the only food elements capable of repairing and building tissue and at the same time producing their quota of energy and heat. It would seem, therefore, that proteids are ideally qualified to act as the mainstay of the diabetic. Certain objections to the excessive use of meats and albuminous foods in the diabetic dietary must be given due consideration. Not only are albuminous foods of themselves an insufficient source of energy for the permanent maintenance of the body, but in the severe form of the disease proteids are known to add to the glycemia by means of the carbohydrate, which is an integral part of the proteid molecule. On this account many cases of this form of the malady are found to do badly on an animal diet. Proteids, moreover, have the effect of stimulating nitrogenous metabolism, and in the excessive destruction of albumin, acetone and other acid toxins are formed which are most prejudicial to the patient's nutrition, and strongly predispose to the development of coma. A less important but still valid objection is that bacterial putrefactive changes of the proteids in the intestines are apt to add materially to the toxemia. Proteids can not be said, therefore, to be conservors of the body tissues in diabetes, but, on the contrary, may, by stimulating nitrogenous waste and increasing the toxemia, prove to have a directly opposite effect. What is needed is true conservation of the tissue albumins, and to accomplish this we must have recourse largely to carbohydrates and fats.

Fat is a compact source of energy, yielding, as we have seen, more than twice as many calories as proteids. It possesses the advantage of not being available as a source of sugar in the economy, as proteids are, and consequently can not add to the hyperglycemia or glycosuria in any stage of diabetes. An additional advantage possessed by fats is that they can, to a considerable extent, fulfill the function of carbohydrates as albumin-sparing bodies, and in this manner they aid materially in the preservation of weight and tissue.

Certain obstacles to the employment of fats in large quantities in the diet exist. They possess a lower percentage of absorption than either of the other two food classes, are more difficult of digestion and less palatable, being apt soon to disgust the taste, so that their availability becomes greatly restricted. For these reasons, notwithstanding their high calorie value, fats can not be ingested in sufficient quantity to cover the expenses of the economy. They do, however, contribute very materially thereto, and richness in fats may be said to be the leading characteristic of the diabetic diet. They are made available to the p ployment of various expedients simultaneous use of carbohydr has been found by experience that their palatability and digestibility are greatly enhanced by this association. Fortunately, all diabetics utilize some portion of ingested carbohydrates, and the calories thus gained contribute better than any other to the protection of the systemic proteids. It is, therefore, never necessary to entirely exclude from the diet this class of foods, the extent of their allowance being a matter of the patient's capacity for assimilating them and the form in which they are permitted. The permanent exclusion of carbohydrates from the food can not be effected, because without them, no matter how careful our arrangement of the dietary may be, the supply of available calories is never sufficient for the systemic needs, excessive tissue breaking down resulting to supply the deficiency, and emaciation and organic toxemia follow.

Authorities are in general accord in condemning the attempt to enforce the absolute non-saccharin diet, except perhaps for a brief period to accomplish some special result. This rule holds good in all forms of the disease. In the mild forms of diabetes, some power of starch assimilation is invariably retained, and to withhold carbohydrates entirely is to deprive the patient unnecessarily of a valuable source of energy. In the severe forms of the disease, not only do carbohydrates entirely fail of assimilation, but at the same time the systemic powers are unable to utilize the carbohydrate constituent of the albumin molecule, which acts on the blood and urine identically as does grape sugar derived from other sources. It becomes apparent, therefore, that too close restriction will avail nothing and merely result in jeopardizing the systemic tissues. As a matter of fact, it becomes as necessary, in the severe stage of the disease, to restrict the nitrogenous exchange as to limit the ingestion of carbohydrates, and in the presence of acid toxemia it is advisable to make an attempt to spare the systemic albumin which is being sacrificed, by free introduction of carbohydrates. It is to be remembered in severe diabetes that it is better to temporize with a glycosuria on a mixed diet than to force an autophagy by overstrictness, for we may fail utterly to subsequently cope with the dystrophy, which has thus received a fillip through our zeal. The weight of authority is unequivocally opposed to a too rigid nitrogenous regimen in all forms of diabetes, but especially in the severe form, it having been proved that acetone and acid toxins result from such a measure. Coma has been precipitated by the sudden institution of a strict non-starchy diet.

It becomes apparent from the foregoing considerations that the course to be pursued in the dietetic treatment of diabetes is, in the amenable stages of the disease, to allow the patient as liberal an allowance of carbohydrates as the patient can assimilate, and in the severe stages as much as is found necessary to hold in check the dystrophic advance, bearing in mind the important fact that carbohydrates only act as albumin-sparing bodies when their ingestion is followed by at least partial assimilation. At the same time every artifice must be employed to introduce the largest amount of fat that the patient can take. If this method is pursued it does not become necessary to restrict the nitrogenous elements of food, for by the judicious introduction of carbohydrates and fats little necessity exists for excessive devotion to any one class of foods, and seldom is the patient led into overindulgence in animal foods. The point is frequently made that it is as necessary to limit the quanity as it is the quality of the foods in diabetes. It ems to the writer an unnecessary cruelty to limit the amount of available foods to these patients, for the bulimia is the outcry of starved tissues, deprived of the food values necessary for their preservation, and to meet this tissue hunger by further starvation seems both cruel and unscientific. A better solution of the difficulty is reached by adjusting the diet, as far as possible, so as to provide sufficient food calories for the systemic needs in easily available forms, such as carbohydrates, fats and alcohol, and when this is successfully accomplished the excessive craving for food disappears.

Some argument exists as to the propriety of suddenly instituting a strict non-starchy diet, even for temporary experimental purposes, to determine the patient's assimilative powers. In decidedly toxic cases, experience has proved that an increase in the acetone and acid toxins is inseparable from the strict diet, and the liability to coma is greatly increased by such a measure. The question of the extent of our restriction seems to be one entirely of the phase of the disease. The general rule may be given that if on a mixed diet the patient's urine does not yield the ferric chlorid reaction one may without danger restrict the carbohydrates. If, on the contrary, the ferric chlorid reaction be present it would be a great mistake to attempt the strict or absolute diet. In such cases there is no physiologic warrant for persisting with diet in the hope of removing the glycosuria. In the most favorable cases of mild diabetes, the absolute diet can not be followed for periods of longer than a few weeks or months. It will generally be found that patients who are fat and not nervous and who have good digestions will bear better the strict diet. Instead of following a blind routine, we must individualize as much as possible and treat each case, so far as indications will lead us, on its own merits. The advantages to be gained by dieting in diabetes do not alone consist in the control of the hyperglycemia and its effects, but experience has proved the important fact that patients who have, for a certain time, been on a diet containing no carbohydrate often acquire a tolerance for these elements and excrete much less sugar after a return to carbohydrates than they did before. The fact has been especially emphasized by Von Noorden, Naunyn, Pavy and Weintraud that the sugar-consuming function of the body is spared by the temporary withdrawal of carbohydrates, and is thus given the opportunity for some recovery and restoration. We avail ourselves in this manner of the important therapeutic principle of rest in subduing functional disturbance. It is impossible, however, to predict an improvement in assimilative capacity after dieting. The reverse may take place. Magnus Levy reports four cases in which prolonged withdrawal of carbohydrates had developed a reduced tolerance for this class of food.

It will be found desirable to place cases on the strict diet for periods of three or four weeks, once or more each year, so as to afford relief to the eliminating organs and rest to the assimilative functions. Beyond this, experience has taught us that even if we exceed somewhat the tolerance for carbohydrates, no great harm is to be feared, since it is not the slight but the excessive glutting of the system with sugar that we must avoid.

103 State Street.

## DISCUSSION.

Dr. Henry Beates, Jr., Philadelphia—If we could only impress on every member of the profession the necessity for demanding elaboration of the so-called fundamental sciences included in the medical curriculum, much would be done to solve, as has been done by the reader of this paper, the complex problems in therapeusis. Experience has taught me that that physiologic teaching prevailing concerning the three types of food is either imperfect or frequently slighted and is commonly absolutely erroneous. Only a small percentage of the profession has a proper conception of these things, and more diabetics have been prematurely brought to their graves because of the pernicious dietetic treatment prescribed than would have been the case had they been left alone. As Dr. Cohen remarked a few moments ago, "What is the dose of anything? Enough." That physician who will cultivate the skill to give enough and only enough of each of the three types of food in treating diabetes mellitus will score that success which it is possible only for scientific medicine to achieve. The paper has, therefore, contributed largely to the knowledge of the scientific treatment of diabetes mellitus, and is an illustration of the need for proper teaching and for the elaboration of the applied phases of the not yet sufficiently appreciated fundamental sciences of chemistry and physiology.

Dr. A. C. Croftan, Chicago—There is great confusion to-day in the mind of the average physician in regard to the question of food and food values. Our knowledge of the fate of foods is still in a more or less rudimentary state; we have only gotten to the point where we consider, on the one hand, the ingested food, and on the other the eliminatory products, so far understanding without the intermediary of food dissimilation. Thirty or forty years ago when a case presented sugar in the urine it was said that sugar must be eliminated from the diet. This recommendation was based on the belief that the food-sugar was the only source of the urinary sugar. Nowadays we know that sugar is formed from the catabolism of fats and albumins, and that a certain proportion of carbohydrate is always required to maintain full nutrition. If sugar is completely excluded from the diet the organism is simply forced to manufacture it from the albumins and fats of its proper tissues. Diabetics should therefore have some carbohydrate, but how much is the great question. I think the solution of this exceedingly difficult problem is to undertake to feed the patients quantitatively, i. e., to take each case individually and to show the ingestion and excretion of sugar quantitatively, and to arrange the diet accordingly. The following has been my habit: First I deprive the patient of all carbohydrates for a short time to determine the sugar excretion, and then slowly, by weight, increase the amount of sugar until I get a small increase in the excretion of sugar. I keep the patient at this point, and do not try to get rid of all the sugar. I figure out that the calorie value of the total food, and allow, on the above basis, as liberal diet of carbohydrates as possible. A point which I think is most pernicious in practice to-day is to content ourselves with a purely qualitative regulation of the diet. We must use our tables, heat values; we are as little justified in guessing here as anywhere else. In one thing I do not agree with the essayist: that is that the weight-test should supplant the sugar-test in diabetes; for if we gauge the results of our treatment of these cases from fluctuation in their weight we may be misled. There are cases in which, as we might express it, the sugar is not excreted in the urine as dextrose, but is converted into fat and deposited in the tissues as fat. These patients gain in weight, but they are suffering from diabetes as much as if there were abundant glycosuria with loss of weight, and the diet should be regulated accordingly. The matter can be regulated with mathematical precision and we should not be willing to incur the risk of underfeeding our patient; that is an error that is committed in a great majority of the cases submitting to a strict régime. Many diabetics and nephritics do not feel very sick, nor do they actually begin to fail, until they consult a physician and are promptly placed on a routine diet that slowly but unerringly starves them to death and robs them of that little reserve of resisting power they may possess.

Dr. O. T. Osborne, New Haven, Conn.—I approve every item in the paper, and I agree with Dr. Beates that a large number of diabetics live along [illegible] until they are examined for life insurance and [illegible] is di[illegible] then [illegible] lent. Heat is a secondary product, the result of cellular activity.

So far as these deductions carry us, the solution of the nutritive problem in diabetes would seem to consist simply of a proportionate increase in the amount of proteids and fats of the food, so as to meet the calorie demands of the organism. The necessity which we have to face, however, is not merely one of substitution for carbohydrates, but a multitude of difficulties complicate the problem. Some means must be devised to terminate the abnormal albumin breaking down, which is so frequently a result of the constitutional vice. Moreover, the digestive welfare of the patient must be duly taken into account, otherwise anorexia, disgust and dyspepsia will vitiate the good effects of our endeavors.

Proteids are the only food elements capable of repairing and building tissue and at the same time producing their quota of energy and heat. It would seem, therefore, that proteids are ideally qualified to act as the mainstay of the diabetic. Certain objections to the excessive use of meats and albuminous foods in the diabetic dietary must be given due consideration. Not only are albuminous foods of themselves an insufficient source of energy for the permanent maintenance of the body, but in the severe form of the disease proteids are known to add to the glycemia by means of the carbohydrate, which is an integral part of the proteid molecule. On this account many cases of this form of the malady are found to do badly on an animal diet. Proteids, moreover, have the effect of stimulating nitrogenous metabolism, and in the excessive destruction of albumin, acetone and other acid toxins are formed which are most prejudicial to the patient's nutrition, and strongly predispose to the development of coma. A less important but still valid objection is that bacterial putrefactive changes of the proteids in the intestines are apt to add materially to the toxemia. Proteids can not be said, therefore, to be conservors of the body tissues in diabetes, but, on the contrary, may, by stimulating nitrogenous waste and increasing the toxemia, prove to have a directly opposite effect. What is needed is true conservation of the tissue albumins, and to accomplish this we must have recourse largely to carbohydrates and fats.

Fat is a compact source of energy, yielding, as we have seen, more than twice as many calories as proteids. It possesses the advantage of not being available as a source of sugar in the economy, as proteids are, and consequently can not add to the hyperglycemia or glycosuria in any stage of diabetes. An additional advantage possessed by fats is that they can, to a considerable extent, fulfill the function of carbohydrates as albumin-sparing bodies, and in this manner they aid materially in the preservation of weight and tissue.

Certain obstacles to the employment of fats in large quantities in the diet exist. They possess a lower percentage of absorption than either of the other two food classes, are more difficult of digestion and less palatable, being apt soon to disgust the taste, so that their availability becomes greatly restricted. For these reasons, notwithstanding their high calorie value, fats can not be ingested in sufficient quantity to cover the expenses of the economy. They do, however, contribute very materially thereto, and richness in fats may be said to be the leading characteristic of the diabetic diet. They are made available to the patient through the employment of various expedients, chiefly by means of the simultaneous use of carbohydrates and alcohol, for it has been found by experience that their palatability and digestibility are greatly enhanced by this association. Fortunately, all diabetics utilize some portion of ingested carbohydrates, and the calories thus gained contribute better than any other to the protection of the systemic proteids. It is, therefore, never necessary to entirely exclude from the diet this class of foods, the extent of their allowance being a matter of the patient's capacity for assimilating them and the form in which they are permitted. The permanent exclusion of carbohydrates from the food can not be effected, because without them, no matter how careful our arrangement of the dietary may be, the supply of available calories is never sufficient for the systemic needs, excessive tissue breaking down resulting to supply the deficiency, and emaciation and organic toxemia follow.

Authorities are in general accord in condemning the attempt to enforce the absolute non-saccharin diet, except perhaps for a brief period to accomplish some special result. This rule holds good in all forms of the disease. In the mild forms of diabetes, some power of starch assimilation is invariably retained, and to withhold carbohydrates entirely is to deprive the patient unnecessarily of a valuable source of energy. In the severe forms of the disease, not only do carbohydrates entirely fail of assimilation, but at the same time the systemic powers are unable to utilize the carbohydrate constituent of the albumin molecule, which acts on the blood and urine identically as does grape sugar derived from other sources. It becomes apparent, therefore, that too close restriction will avail nothing and merely result in jeopardizing the systemic tissues. As a matter of fact, it becomes as necessary, in the severe stage of the disease, to restrict the nitrogenous exchange as to limit the ingestion of carbohydrates, and in the presence of acid toxemia it is advisable to make an attempt to spare the systemic albumin which is being sacrificed, by free introduction of carbohydrates. It is to be remembered in severe diabetes that it is better to temporize with a glycosuria on a mixed diet than to force an autophagy by overstrictness, for we may fail utterly to subsequently cope with the dystrophy, which has thus received a fillip through our zeal. The weight of authority is unequivocally opposed to a too rigid nitrogenous regimen in all forms of diabetes, but especially in the severe form, it having been proved that acetone and acid toxins result from such a measure. Coma has been precipitated by the sudden institution of a strict non-starchy diet.

It becomes apparent from the foregoing considerations that the course to be pursued in the dietetic treatment of diabetes is, in the amenable stages of the disease, to allow the patient as liberal an allowance of carbohydrates as the patient can assimilate, and in the severe stages as much as is found necessary to hold in check the dystrophic advance, bearing in mind the important fact that carbohydrates only act as albumin-sparing bodies when their ingestion is followed by at least partial assimilation. At the same time every artifice must be employed to introduce the largest amount of fat that the patient can take. If this method is pursued it does not become necessary to restrict the nitrogenous elements of food, for by the judicious introduction of carbohydrates and fats little necessity exists for excessive devotion to any one class of foods, and seldom is the patient led into overindulgence in animal foods. The point is frequently made that it is as necessary to limit the quantity as it is the quality of the foods in diabetes. It seems to the writer an unnecessary cruelty to limit the that term to cover a large series of cases, but that they are cases of acute pancreatitis, and that we delude ourselves by calling them diabetes. Cases dying of "diabetes" do not all have diabetes, but some have pancreatitis. Within the last year or two I saw a young man who, within three months after an attack of typhoid fever and when well enough to travel, when fifteen hundred miles from home, was comparatively suddenly seized with this sudden loss of weight and strength and the appearance of sugar in the urine, and I said it was a case of acute pancreatitis. The patient died, but no autopsy was held.

DR. W. W. TOMPKINS, Charleston, W. Va.—In West Virginia I have frequently asked older physicians about diabetes in the negro. Although possibly one-fourth of our population is of the negro race, and although they have typhoid fever and the other serious diseases from which we suffer, I have never seen a case of diabetes in them, nor could I find another practitioner who had done so. Before the war insanity was unknown among the negroes, but since that time it is not uncommon. Has Dr. Elliott ever personally treated diabetes in the negro?

DR. A. R. ELLIOTT—I have never seen a case of diabetes in the negro. Dr. Tyson a few years ago stated that he had never seen a case in the negro. It is extremely rare in the negro, but common among other colored races, as the East Indians. I agree with Dr. Webster that glycosuria of a pancreatic type may be brought about as a result of typhoid fever. It seems to me reasonable to suppose that inasmuch as the infection may spread from below up the common bile duct to the gall bladder and liver, we may also have an infection spreading over to the pancreas with resulting inflammatory changes in that organ. In regard to the further investigation of the occurrence of ulcers in the bowel in diabetics, I have no information. It is well known that colitis is a very frequent complication in diabetes, produced no doubt by the irritation of hardened fecal matter in the lower bowel. For this reason it has always seemed to me one of the most important therapeutic measures to keep the lower bowel well cleared of fecal matter by enemata to prevent any tendency to coprostasis. I agree with Dr. Beates that many patients are overdieted, and sometimes rue their consultation with physicians. It is not uncommon to hear an old diabetic regret that he ever consulted a physician because, whereas he was in good health before that time, he has suffered ever since in the attempt to combat the disease by dieting. That is unquestionably due to a misconception of the dietetic problem, and the patient is unwarrantably condemned to a strict diet. I believe the attention of the profession is focused entirely too much on the glycosuria, and my general statement that the weighing scales are a better criterion for success in our practice than the presence of glycosuria I believe is true. I am glad to accede the point made by Dr. Croftan that this statement is capable of exception. Since I wrote this paper a case has come to my attention to refute my own statement. In a young girl who has been diabetic for a year and a half, the disease has assumed a vicious toxic form, and diacetic acid and acetone are present in the urine; yet she is gaining in weight. She is very toxic, and her breath smells of acetone.

---

# EMPYEMA OF THE ANTRUM.[*]

O. N. HEISE, M.D., D.D.S.

CINCINNATI.

In looking over the literature of the above-named subject I have again and again been impressed by the few references to the difference between a cystic empyema, so called, and a true empyema, the one being due to the encroachment of a dentinal or alveolar cyst to the antrum, the other a true infection of the antrum either from dental or nasal origin.

In an article on empyema of the antrum in one of our leading dental journals not long ago I noticed a statement as follows:

> Within the last few years a comparatively new affection, frequently confounded with antral empyema, has appeared. Dentigerous cysts arise as you know about the tooth roots and slowly dilate the tissue at the root of the tooth.

I quote this principally to show that affections of the teeth and alveolar process in relation to antral troubles do not receive the attention they deserve. If the author of that article had taken the trouble to inform himself he would have found that it was not a new affection, also that a dentigerous cyst is a different condition of affairs from that he states it to be.

These maxillary cysts, when found in the neighborhood of the molars and bicuspids can, and do, in their development, raise or push the floor of the antrum to such an extent that finally the thin intervening lamella of bone is resorbed, leaving only the periosteum and the lining mucous membrane of the antrum as a covering. I have often seen the encroachment such as to include the entire antrum, filling it completely, in its further development raising both outer and inner wall, as well as the roof.

Antral cysts developing within the cavity must of necessity first completely fill it before they can produce any abnormality in the way of bulging of either wall, and can, I think, be recognized as having their origin from within, instead of having developed within the alveolar process. The facial wall, being extremely thin, owing to the resorption of the bone, leaves at times a decided defect in the wall, whereas in the dental or alveolar origin the thinness of the wall is found to be in the alveolar region or process. They are more frequent than has been supposed, not only in connection with antral lesions, but in other regions of the alveolar process; both in the upper and lower maxilla. Many an abscess has been treated with little or no success, tooth finally extracted, socket curetted, packed, etc., thinking it to be either a case of caries or necrosis; whereas, if the proper diagnosis had been made, the tooth could easily have been saved by proper treatment, especially the single-rooted teeth.

The domain of the stomatologist runs very closely into that of the rhinologist. Every now and then in the treatment of an obstinate antral suppuration we find that the trouble is not so much in the antrum as in some of the accessory cavities, draining into the antrum, making a reservoir, so to speak, of it, treating only the effect, not the true cause in such instances. This fact, and also the frequent occurrence of empyema after la grippe, has led some men to almost doubt the dental origin of antral empyema. There is no question at all in my mind that many antral cases are primarily due to infection from some accessory cavity, or other nasal disease. Nevertheless, dental causes are, and will remain, prominent etiologic factors.

The difference of opinion as to the main causation of antral empyema depends greatly on the view-point taken. Reminding one of the oriental story of the three blind men who went one day to inspect an elephant: "He is like a spear," said one who grasped the tusk; "he is like a fan," said another who felt the ear, while the third with his hand on the leg declared he was like a tree. They had all inspected the elephant, but, naturally, formed different ideas of his appearance. So it is with the etiology of antral empyema. Various observers form various views from various experiences, while if all would inspect every case and judge of its cause and treatment on its own individuality it would be seen that there is ample room for all opinions in considering this interesting subject.

---

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

I will not discuss which etiologic factor, nasal or dental, is most frequently found to be the cause of antral suppuration, but it has seemed to me that of late the dental relationship to antral empyema has been somewhat overlooked, not only being frequently the cause, but having a decided influence in keeping a certain amount of irritation, thereby preventing a complete cure. I want, therefore, to bring this phase of the subject to your notice.

That many affections of the nasal cavity and antrum are due to diseased teeth, etc., is not to be doubted. Not only abscessed teeth, but oftentimes carious and even filled teeth, especially the superior incisors, are the cause of nasal disturbances. Ziem of Danzig was one of the first to point out the important relationship existing between diseased teeth and abnormalities of the nasal mucous membrane and antral troubles. He reports a number of cases showing that any carious tooth in the superior maxilla and sometimes even in the inferior maxilla, can by reflex action bring about hypertrophic rhinitis, and sounds a note of warning against the imperfect treatment of carious and diseased teeth, especially the molars and bicuspids. It was due to his investigations that in the year of 1886 the real impetus to the study of antral empyema was given, showing conclusively that they were far more common than heretofore supposed or believed—Ziem himself being a sufferer from an antral empyema due to a diseased tooth. He also was the first to designate the condition, "empyema of the antrum," which, however, is not altogether a correct term, inasmuch as an empyema from a pathologic standpoint is a collection of pus in an enclosed cavity of the body. In the so-called empyema of the antrum we have the collection of pus, but not in a completely enclosed cavity, as we have a continual or an occasional discharge of pus from it. It is useless, however, to find fault with the term until we have a better and more appropriate one to apply to it.

Since Ziem's first important contribution to this subject and the other accessory sinuses of the nose, Zuckerkandl's numerous dissections, as well as P. Heymann, Moritz, Wolf, Harke and others, it has been shown that diseases of the accessory sinuses are anything but infrequent; in fact, they are the rule almost in acute infectious diseases, but, fortunately, will—if the natural openings are normal and not closed by some diseased condition of the nose—end in a spontaneous cure. That some do not end this way is due, according to M. Schmidt and E. Fränkel, "to the varying virulence of the bacteria and the individual disposition of the patient." It is, however, "rather strange," as pointed out by M. Schmidt," "that the various sinuses being so frequently affected in cases of la grippe, should show the presence of the influenza bacillus so seldom—only in 1 case out of 30," according to E. Fränkel's examinations.

Grünwald has well said:

> The great frequency of inflammation of the antrum of Highmore, which follows from the anatomic position of the cavities, rendering them liable to infection by the extension of a process from the inferior turbinate, and favoring the isolation of the morbid process within them by the swelling of the surrounding tissues, and by the high position of the office above the floor of the cavity is enhanced by the proximity of organs like the teeth that are so prone to become diseased. Accordingly, infection of the antrum of Highmore derived from a diseased pulp by way of the lymph channels, and catarrhal condition due to irritation accompanying coronal caries, are common and inversely; catarrh of the antrum may give rise to periodontitis and thus establish a vicious circle, so that the antrum disease persists even after other causes have been removed. As infection creeps along the lymphatics of healthy bone, a focus of infection in the crown of a tooth is by no means to be despised; for even if an empyema of the antrum be due to another cause, yet disease of the crown of a tooth is calculated to maintain such a state of irritation in the mucous membrane as may frustrate all attempts at a cure.

The apparent non-attention on the part of a great many practitioners to the influences that diseased teeth, as well as diseased conditions of the gums and alveolar process have, not only as an etiologic factor, but in maintaining a process once set up in the antrum, is a matter which demands our attention.

In an excellent article on the Heilbarkeit der Kieferhöhlen entzündungen[1] Grünwald gives very interesting and convincing statistics regarding the influence of the teeth in the treatment of antral affections, namely:

> In 31 antra of 20 patients who had sound teeth, or apparently so at least, 39 per cent. were cured, 23 per cent. almost cured, 16 per cent. improved and 23 per cent. unimproved; whereas in 28 antra of 19 patients, in whom the decayed teeth influencing the condition of the antrum were extracted, 65 per cent. were cured, 17 per cent. almost so, 14 per cent. improved and only 5 per cent not cured.

Grünwald explains that "in cases of those patients having apparently sound teeth there must have been some diseased condition present, in the way of a periodontitis, which was, and is, often overlooked in cases, even by dentists," as he on a number of occasions referred the patient to them, and they refused to extract the tooth or teeth on account of the apparent soundness of them. The chances of overlooking any connection or influence that apparently sound teeth have in keeping up the suppurative process are much greater, as it is easy to overlook a diseased condition of the roots of the teeth—whereas, in the cases where teeth were found to be diseased, and either acted as a direct cause of the empyema, or were to a certain extent responsible for the original trouble in the antrum, or in keeping up the suppurative process, the extraction of them alone was a prime factor in the cure of the affection, but does not of itself in the majority of cases suffice to bring about a complete cure, inasmuch as the mere puncturing of the antrum does not show any brilliant results.

That not enough attention has been bestowed on this matter has been shown by the fact that in a number of cases treated according to the accepted methods of to-day suppuration would persist until the teeth involved in keeping up the process had been extracted, showing conclusively that although they might not have been the original cause of the suppuration, nevertheless they were active factors in preventing a complete cure. Grünwald also cites a number of cases to show the important relationship existing between diseased teeth and suppuration of the antrum.

There seems, however, to be a decided difference of opinion between the anatomists and clinicians regarding empyema of dental origin. The former asserting, as no microscopic evidence of any inflammation or change of structure is found on section of the antrum between the roots of the teeth and the cavity, that the teeth decayed or diseased play little, if any, active part in its production.

---

[1] Archiv f. Laryng. u. Rhinol., 1889, Heft 3.

They do admit occasionally to have found sufficient dental cause. Zuckerkandl in 300 cases only could trace one as being due to dental causes. The same with E. Fränkel, while Dmochowsky never found any evidence. Hajek in this connection remarks:

> This marked difference of opinion of anatomic and clinical evidence is due to the fact that in the course of time all evidence which would point to a disease of the alveolar process or teeth is, or has been, entirely lost, as it is quite possible for the germs to have penetrated through the alveoli of the teeth and the intervening bony plate, as is the case in an affection of the meninges in frontal sinus and sphenoidal empyema without leaving or producing any macroscopic changes in the bone.

Kyle states: "Too much importance can not be attached to the teeth as a causal factor in antral lesions." A majority of cases he believes are due to diseases of the teeth and gives the percentage as high as 70, also states that it may be a postoperative complication of nasal and dental surgery. One case observed by him was due to the use of arsenic applied for the destruction of a pulp in a decayed tooth. The application was made twice in three days and not seen for several days afterward, when the antrum was involved, and extensive tissue necrosis had occurred with infection (evidently due to a very careless application of the arsenic). In another case extensive necrosis and suppuration had followed the injection of chlorid of zinc into a tooth cavity which connected with the antrum.

The relationship between diseased conditions of teeth and the upper jaw, gums, alveolar process and antral troubles as well as some lesions of the nose, is an intimate one, and should be taken into consideration more frequently than it is. As Kyle has well said:

> A thin alveolar process of upper jaw from lesions of the teeth may cause by extension of inflammation, by continuity of structure, lesions of the floor of the nose or of the antrum; on the other hand, deflections of the septum or spurs situated close to the floor of the nose, by the inflammatory action set up in the surrounding structure, may bring about inflammation and diseased conditions of the teeth in the direct line of obstruction. The stomatologist should, therefore, not only have a thorough knowledge of the nasal cavities and accessory sinuses, but also of general medicine; and, indeed, the general practitioner or specialist should have a more thorough knowledge of stomatology.

## DISCUSSION.

Dr. Thomas L. Gilmer, Chicago—Dr. Heise has done well in differentiating between a pus sac at the end of a root of a tooth and the so-called empyema of the maxillary sinus. I do not know whether I can agree with him in the nomenclature. We are often defective in diagnosis of the various diseases to which the antrum is subject. For instance, take the condition spoken of in the paper, denominated cystic empyema, and the condition called true empyema. It may be very difficult to diagnose between these two conditions, although there is a vast difference. This is especially true if the ostium maxillary be closed, then practically both are encysted. In neither case will pus be found in the nose. In the encysted condition pus will not escape into the nose because it is enveloped in a cyst wall; in the other it does not escape, because the normal outlet from the sinus is closed. Sometimes a tooth is found with a septic root closely approximating the floor of the antrum, and as a result a pus sac may form on the end of the root, and by enlargement cause pressure sufficient to absorb the thin layer of bone overlying, and the sac continuing to grow, may in some instances completely fill the sinus. The patient may have all of the symptoms of empyema, transillumination gives a shadow, there is thinning of the nasal and buccal walls and protrusion of the eye from pressure below, but there is no appearance of pus in the nose. If the fact can be established that there is no stenosis of the ostium, then the indications are that it is either a cyst or a new growth. My clinical experience leads me to the conclusion that the two principal causes of empyema of the maxillary sinus are extension through continuity of tissue of an inflammation from the nose, and from septic roots of teeth, the former being by far the more common cause. Since the prevalence of influenza in this country, disease of the maxillary sinus has become much more common, indicating that the nose is a fruitful source of the disease. While it is true that septic roots of teeth are occasionally a primary cause of empyema of the maxillary sinus, still I am of the opinion that they are more frequently a secondary rather than a primary cause. For instance, as a result of a catarrhal condition of the lining membrane of the antrum there may be an inflammation of sufficient consequence to cause the death of the pulp in the root of a tooth. In some instances on the floor of the antrum immediately over the buccal roots of the first and second molars, and over the end of the root of the second bicuspid there are slight elevations of very thin bone, corresponding to the roots of these tusks. The mucous membrane over this thin area of bone becomes inflamed, the inflammation extends from the lining of the sinus to the pulp of the tooth, causing its death. After the subsidence of the catarrhal condition there is left at the end of the root a source of infection which will probably continue the disease of the antrum as an empyema. Under such circumstances the root was a secondary rather than a primary cause. My experience teaches me that it is useless to attempt to cure a case of empyema, caused by a pulpless tooth, if the apex of the root projects into the floor of the sinus, until the tooth is removed. If only drainage is needed for a cure then I would open through from the middle meatus of the nose. If the sinus contained granulation tissue, polypi or any condition demanding curettement, I should open from the buccal wall of the cavity, making the opening sufficiently large to admit the little finger. Digital examination affords a much more satisfactory means of exploring the cavity than does an instrument. I prefer to make such an opening rather than through a tooth socket, 1, because it is impossible to reach every part of the sinus for curettement through a tooth socket; 2, because, if the opening is made through the buccal wall the cheek falls over the opening and in a large measure prevents food from getting into the cavity. An opening here also permits the introduction into the cavity of a small electric lamp for examination during treatment. I am of the opinion that arsenic should almost never be used for the destruction of pulps of teeth. The application of cocain makes the immediate removal of pulps painless and practicable, therefore its use is preferable. In some instances there are accessory or additional openings in the sides of the roots of teeth larger than the apical foramen, through which arsenic may pass and do much harm. I can not conceive why chlorid of zinc or carbolic acid should be used in such cases.

Dr. M. H. Fletcher, Cincinnati—In 1893 Dr. Talbot and I went through the Army Medical Museum to study the anatomy of the antrum. The tubercle of bone over the roots of the teeth, as pictured on the board by Dr. Gilmer and as shown and described by Gray, Quain, Zuckerkandl and other anatomists, was found[1] in only 12 antra out of 1,000. On the other hand, in a large per cent. of cases there was no bony covering over the apices of the teeth, the apex of the tooth coming directly against the soft tissues of the floor of the antrum. We all know that on the buccal surfaces many of the apices of roots are bare of bone, being simply covered by mucous membrane and, as I have stated, many apices are also bare in the antrum. An abscessed tooth with the conditions of anatomy described would undoubtedly discharge in the antrum, the pus going in the direction of least resistance. I have seen several cases of such perforation with a dental abscess discharging into the antrum. In these instances healing took place, under treatment, as readily as if the opening had been through the alveolar process. It is my experience that pulpless teeth producing antral trouble yield to treatment as readily as though they discharged into the mouth. On the other hand, recent experience has caused me to believe that disease of the alveolar process from calcareous deposits is more largely to blame for antral trouble than are pulp lesions. It never has been my experience in examination either of skulls or of patients to see a bicuspid that came very near the floor of the antrum. I have seen these openings referred to by Dr. Gilmer. I fail to recognize any condition about the pulp of a vital tooth which would cause antral disturbance. Arsenic is a favorite remedy of mine. I have used it almost ever since I have been practicing, and it is my habit, if I feel that I have failed in perfectly opening a root canal, to insert some arsenic as far into the canal as possible and leave it there, expecting it to continue to produce asepsis and prevent future trouble. I have done this a great many times and have yet to see antral trouble produced. I do not, however, use arsenic to any degree in destroying pulps.

---

[1] "Some Suggestions as to the Relation of the Teeth to Empyema of the Maxillary Sinus," M. H. Fletcher, The Journal A. M. A., Dec. 30, 1893.

**Dr. H. E. Belden**, New Orleans—In view of the fact that you use arsenic at all, what is your objection to using it in destroying pulps?

**Dr. Fletcher**—If enough is used to destroy the pulp in a reasonable time it is sufficient to cause trouble afterward. As to the use of zinc and other medicaments which destroy bone, I have seen carbolic acid destroy a large area of the alveolar process, but I never have seen arsenic do that. Arsenic, however, if applied to live tissues will destroy a small zone. In my experience it never has produced necrosis, as that term is accepted in pathology. It may produce destruction of tissue, but the condition may be compared to traumatic injury. The tissues do not continue to die progressively as in ordinary necrosis. It has also been my experience that the tissues will remain sore for months if the application is short of destruction of tissue. There is, however, in these cases no septic condition, no necrosis, no pus. The arsenic stops this process.

**Dr. Gilmer**—Have you not seen the destruction of bone between the teeth from the use of arsenic?

**Dr. Fletcher**—I never have.

**Mr. Constant**—I have on three occasions.

**Dr. Gilmer**—I have seen it many times.

**Dr. Fletcher**—The essayist has distinguished between a cystic condition and that of empyema. I have to stretch my imagination considerably to think of a tooth producing the cysts as he has described.

**Mr. T. E. Constant**, Scarborough, England—In my experience it has been very exceptional to find a case in which disease of the antrum could be definitely traced to the tooth. In regard to determining cause and effect, I am sure that to consider many cases of so-called empyema as due to abscess connected with the tooth is putting the cart before the horse. I can recall two cases in which empyema of the antrum was supposed to be due to trouble in the first molar. When the first molar was removed it was found possible to evacuate the pus and that was taken as proof that the tooth caused the trouble. I could not convince myself that the tooth was the cause of the trouble. I think the fact that the apices actually went into the antrum made it easy to get the discharge in that way. I agree with Dr. Fletcher that it is far more common to find the apices of teeth bare within the antrum than to find them covered. A great number which I have examined in England show that.

**Dr. M. L. Rhein**, New York City—I feel convinced from a careful study of this subject that the cases in which the teeth are the primary etiologic factors are very rare. The tooth generally becomes involved through pathologic conditions arising between the end of the root and the antrum. I think it is wise to emphasize this point.

**Dr. Fletcher**—Dr. Talbot and I found that the molar teeth produced this trouble in about 5 per cent. of cases.

**Dr. A. E. Baldwin**, Chicago—I firmly believe that arsenic can seldom if ever affect the tissues beyond the pulp of the tooth. Dr. Gilmer has referred to the septum being lost by the careless application of the arsenic by the particles getting down between the teeth.

**Dr. Gilmer**—I spoke of the particles on the sides of the root which I have found and have been able to pick off.

**Dr. Baldwin**—Years ago I suspected that arsenic or arsenious acid might act beyond the pulp and I made several examinations in this way: In a central incision I would make application to the pulp of the tooth, and after a sufficient time remove the pulp. I then took several sections of the pulp, but could find no evidence of the arsenic in the several parts beyond the point of contact. I do not think, therefore, that the pulp could convey the arsenic to the adjacent tissues. I think a great deal of the injury is done by the careless application of the arsenic and the ease with which it gets outside of the tooth, causing the destruction of bone and soft structures.

**Dr. G. L. Curtis**, New York City—I think there are very few diseases of the antrum of a primary nature, and that a large proportion of the diseases of the antrum are caused by affections of the teeth. Tuberculous conditions are sometimes responsible for the absence of success in treating these cases. The cystic condition usually found in the antrum is, I believe, largely due to alveolar abscess, or to septic conditions of the pulp or of the canal of the tooth. I have seen some cystic tumors where there was extended absorption of the bone, and where the periosteum of the antrum was so crowded toward the opening at the nares that there was practically no antrum left. The reproduction of the bone in such cases is a most difficult task.

# THE *X*-RAY AS A THERAPEUTIC AGENT:

## WITH ESPECIAL REFERENCE TO CARCINOMA.*

ARTHUR DEAN BEVAN, M.D.
Professor of Surgery, Rush Medical College, University of Chicago; Surgeon of the Presbyterian Hospital.
CHICAGO.

In attempting to arrive at a correct estimate of the *x*-ray as a therapeutic agent we are confronted at the outset with a number of difficulties: (1) By the fact that this force has been known but a short time and that little is known of its exact nature, so limited is our knowledge that we can not even measure with any degree of accuracy the amount which we are employing in a given case. (2) The agent has been employed but a very short time as a therapeutic agent, and sufficient time has not elapsed to enable us to determine the permanency of the results obtained. (3) Although an enormous amount of work has been devoted to the subject and an enormous number and variety of cases have been treated during the last three years, still for the most part this has been done in a haphazard way by all sorts and conditions of medical men, on all sorts and conditions of patients, and little reliance can be placed on many of the reports made.

I think that it would be safe to say that up to the present most of the *x*-ray work has been done by two classes of men—enthusiasts whose statements and reports were made unreliable by their enthusiasm, and, second, by physicians who simply saw in an *x*-ray apparatus a means of increasing their professional incomes, and did not hesitate to cry loudly the value of their wares.

We do not lack evidence on the subject of the therapeutic value of the *x*-ray. We have before us an enormous mass of evidence. The difficulty is to separate the truth from the error. We have before us, however, a certain amount of scientific well-observed work, done by well-qualified men, whose reports and opinions command general acceptance, from which we can determine approximately at least the present status of the $x$-ray as a therapeutic agent—its value, and its dangers and limitations.

---

* Read before the New York State Medical Society, 1903.

Very shortly after the discovery of the $x$-ray I became interested in the subject as a means of diagnosis, and very early became familiar with the peculiar power which it possesses of destroying living tissues, especially epithelium, as shown by some extensive $x$-ray burns. As early as 1898 I employed it in a case of lupus, which has recurred after extirpation and skin grafting, but without benefit. We obtained a marked $x$-ray reaction in this case after a few exposures, but we could not see any evidence of improvement, and we discontinued treatment.

When my attention was again called to the subject by favorable reports in cases of lupus and epithelioma I was exceedingly skeptical—I might say brutally skeptical. I had shortly, however, an opportunity of seeing cases of lupus and epithelioma and recurring carcinoma of the breast, which had disappeared under $x$-ray exposures, and I began experimenting with similar cases in my own service. I was greatly impressed by the cases of recurring breast carcinoma, where nodules of considerable size, and demonstrated by the microscope to be carcinoma, disappeared under the treatment.

Everyone who has watched such cases must have been convinced that in the $x$-ray we possess an agent of great power and great possibilities in the treatment of malignant disease.

In 1902, at the Saratoga meeting of the American Surgical Association, I made a report of my early work, and again, at the last meeting of the American Surgical Association at Washington, I presented a paper in which, from the evidence at hand, I attempted to estimate the value and limitations of the $x$-ray as a therapeutic agent in carcinoma. I shall quote rather freely from this report. I desire to say that in the last year and a half nothing strikingly new has been added to our knowledge in this department. The experience and evidences obtained during this period have been rather of a kind which demonstrated to us the marked limitations of the agent, and demonstrated the dangers associated with its employment.

I shall confine my statements to classes of cases which I have had the opportunity of personally observing. I shall not mention the many skin lesions in which the $x$-ray has been employed, with reported favorable results, as I have little personal knowledge of this side of the subject with the exception of blastomycetic dermatitis, and I shall refer to this because it has some bearing on a point which I shall later bring out.

Several years ago when I first suggested the internal use of iodid of potassium in blastomycosis in a case reported by Hyde, Hektoen and myself, it was found in this and later cases that the iodid profoundly influenced the disease. It was noted, however, that some resisted the treatment, and that although a decided improvement was obtained, the lesion often did not clear up entirely, and recurred after cessation of the treatment. It has since then been found by Hyde, Montgomery, Pusey and others, that the combined action of the iodid internally and the $x$-ray is successful in curing these obstinate cases where neither alone would suffice. I regard this as a very instructive and suggestive point, which, as I have stated, I shall refer to later.

In lupus the evidence is somewhat conflicting. The $x$-ray does cure lupus, but the experience of the majority of workers in this field seems to speak in favor of the Finsen treatment as the treatment of choice. In our hospital we are now using a modified Finsen lamp instead of the $x$-ray in our lupus cases.

In Hodgkin's disease uniformly favorable results have been obtained as far as decrease or disappearance of the enlarged glands is concerned. In some cases this has been accompanied by profound toxemia, resulting apparently from poison introduced into the circulation from the rapidly breaking down glands. Sometimes this has been fatal. In some of the cases with the disappearance of the glands there was no general improvement, the patients growing weaker and the cases terminating fatally after a considerable period. In others the glands, after disappearing, have later recurred. In some cases, however, the glands have disappeared, the patient's condition has improved to a point where they were apparently cured, and this has occurred in a sufficient number of cases to warrant the careful use of the $x$-ray as an important, if not the most important, factor in the treatment of this disease.

In leukemia, in both the spleno-medullary and lymphatic types, marked diminution of the spleen and involved glands has been observed after the use of the $x$-ray, with improvement in the blood condition. The evidence here, however, is as yet not sufficient to warrant the drawing of any conclusion.

In tuberculosis, outside of lupus, as tuberculosis of lymphatic glands, bones and joints, peritoneum and intestines, the reports are very conflicting. In a personal communication one of the men who has had a wide experience in $x$-ray therapy and who has followed his work most thoroughly and scientifically, informs me that he believes he is curing 90 per cent. of tuberculous lymph glands. Our own limited personal observation, on the other hand, has given us small encouragement.

We have not employed the agent in tuberculosis of bones or joints. In tuberculosis within the abdomen, of peritoneum and intestines, we have had the opportunity of noting some interesting results. One case of hyperplastic tuberculosis of the descending colon, with circumscribed abscess from perforation, was operated on and the abscess drained. A fecal fistula remained. This was closed by a second operation, and the patient placed under the $x$-ray every other day for a period of five or six months. During this period moderate doses—75 grains a day—of potassium iodid were employed. Under treatment the patient has gained 40 pounds in weight, has regained his strength, and returned to his work (manual labor), and the fist-sized mass in and about the colon has almost entirely disappeared. We can not, of course, establish a definite relationship between the $x$-ray treatment and the improvement. I simply report the facts for what they are worth.

Several cases in the service of Dr. Frank Billings' of peritoneal tuberculosis with tuberculous masses and with large amounts of fluid in the peritoneal cavity, which I had the opportunity of observing, have, while under rest and the $x$-ray, improved greatly, the masses and fluid both disappearing.

In regard to this whole subject of tuberculosis, outside of lupus, I should say that we must regard the question as still open, and as a promising field for future experimentation. Sarcomas have been made to melt down and disappear under the $x$-ray. The evidence on this point I think can not be doubted. However, as a treatment for sarcoma the $x$-ray has been most unsatisfactory in our hands. Sarcomas from the position from which they spring, i. e., mesoblastic layer, are essentially deep-seated. If we could spread out the cells of a sarcoma as a thin layer on the surface of the skin I have no doubt that the *x*-ray would destroy them as it destroys the epithelial cells in epithelioma, or if we should leave a great open wound after the removal of a sarcoma so that we could directly, without much intervening tissue, apply the *x*-ray to the cells which might remain after operation we might obtain favorable results. As an example of this point, I want to refer to a glioma of the orbit which recurred after operation in which the *x*-ray could be brought in immediate contact without intervening tissue and where disappearance of the growth and an apparent cure was obtained.

I think the same conclusions can for the most part be applied to sarcoma as apply to deep-seated carcinoma, which we shall later discuss.

*In regard to the effect of the x-ray on carcinoma,* we may speak with more confidence and say that the facts which are to-day fairly well established are the following:

1. The *x*-ray will destroy the epithelial cells of carcinoma superficially situated as in epithelioma. The *x*-ray seems to possess a selective action on the epithelial cells of carcinoma, due probably to their possessing lower resisting powers against the agent than that possessed by normal epithelial cells. When superficially situated so that the furthest cells are within a centimeter of the surface, a mass of carcinoma melts down under the *x*-ray, the individual cells dying become granular and are absorbed without gross evidence of necrosis or of tissue change, beyond that of reddening of the surface and the so-called *x*-ray reaction. Sometimes, however, where a large mass of carcinoma is attacked, it may soften and break down, and be separated from the normal tissues something like the breaking down of a gumma.

When the carcinoma is very thin and very superficial, as an epithelioma of the face, of the rodent ulcer type, not yet involving the tissues underlying the skin, the disappearance of the lesion and the restoration of the surface to almost normal, with slight evidence of scar tissue, can confidently be looked for after about 20 exposures of 10 minutes daily or every other day, with a soft tube from 30 to 110 volts and 2 to 4 amperes.

When the epithelioma is a thick mass of new tissue, as an epithelioma of the lower lip as thick as the finger, the *x*-ray will produce extensive change with destruction of many of the carcinoma cells, and sometimes of all of them with resulting cure. More frequently, however, even under the treatment the process will extend and the lymphatics become involved.

In recurring carcinoma of the breast with recurrence in and about the scar, with nodules in the skin and immediately beneath this, the *x*-ray will produce an absorption of the masses even of considerable size—the size of an English walnut. If these masses are the only locations of carcinoma in the body, a cure might be hoped for with their disappearance, but, unfortunately, with these masses are usually masses in the mediastinal and other lymph glands, and, in spite of the disappearance of the skin masses, the patient goes on to death from general carcinomatous invasion, apparently, however, being benefited to some extent both locally and generally by the treatment.

In cases of deep-seated carcinoma such as stomach, larynx, superior maxilla, mouth, etc., I have seen no evidence of benefit beyond the statement of the patients that they felt better, had less pain, etc., some improvement in general condition. In every case the lesion extended, and in none was a cure obtained.

In estimating the value of the *x*-ray in the treatment of carcinoma there are three facts which must be especially considered and which seem to control largely the *results:*

1. The situation of the lesion, whether superficial or deeply situated.
2. The rapidity of the growth of the cells and the resisting power of the carcinoma cells in the particular case.
3. The size of the new growth.

In regard to the first, the destructive action of the *x*-ray on cancer cells is in direct proportion to their superficial position, i. e., the more superficial, the greater the destructive effect; the deeper, the less the destructive effect. The depth at which the destructive effect (of the *x*-ray on cancer cells) can, with our present technic, be with any confidence expected does not seem to greatly exceed a centimeter. In regard to the vitality of the cancer cells in the particular case, I think it is quite clear that the cancer cells differ markedly in different cases in regard to their resisting power to the *x*-ray. The rapidity of the growth seems to be a fair index of their resisting power to the *x*-ray., the very slowly-growing cancer having less, and the rapidly-growing greater, resisting power. Depending on the differing resisting power and the superficial or deep situation, some lesions disappear under the *x*-ray treatment, some remain stationary and some continue to grow even while under treatment, apparently unaffected by it. The size of the lesion is of importance and the value of the *x*-ray varies in inverse proportion to the size of the growth, the smaller the growth, the more evident the effect, the larger, the less effect. A small superficial epithelioma is readily destroyed; a thick, large epitheliomatous mass, with difficulty or not at all, by any amount of the agent which it is permissible to employ, and even though many of the cells in such a growth may be destroyed, enough remain to bring about regional infection, which may become evident even during treatment.

The question which has been asked, i. e., whether under some circumstances the *x*-ray stimulates the growth and dissemination of the cancer cells, is one which it is at this time difficult to answer. Personally, I have seen no evidence of this. I have seen, to be sure, cases of cancer grow with great rapidity and widespread dissemination occur while the cases were under treatment, but we see the same thing happen frequently in cases which are not under any form of treatment, and I have interpreted the cases, when rapid growth occurred while under the *x*-ray treatment, simply as being cases which were not influenced in any way by the agent and believed that the same rapid growth and dissemination would have occurred with or without the *x*-ray treatment.

What should be our position in regard to the use of the *x*-ray as a therapeutic agent in carcinoma?

It is, I believe, the treatment of choice in slowly-growing superficial epitheliomas, the rodent ulcer type, especially those of wide extent without regional involvement, and especially lesions of this kind situated about the face and eyelids where a radical removal of the lesion with the knife would result in marked disfigurement and deformity from the resulting scar, even when skin grafting is employed. In all other forms of carcinoma, where [illegible] h or more deeply situated than the skin, or even when limited to the skin is of considerable thickness, the case should be treated by extirpation and followed by a course of *x*-ray treatments, probably, as a rule, about 20 exposures immediately after the healing of the operative wound.

I think that this position—this combination of the knife and the *x*-ray—is logical on the following grounds:

1. With the exception of the carcinomas of the rodent ulcer type above described, little can be expected from the *x*-ray in the treatment of primary carcinoma, therefore no time should be lost with its use, and, where conditions warrant, the carcinoma should be widely extirpated in accordance with approved surgical methods.

2. As has been repeatedly shown (especially in cases of breast amputation for carcinoma where recurrence has taken place in and about the scar), these secondary masses can be made to disappear with the use of the x-ray. There can be but little doubt that these secondary nodules, masses of epithelial cells the size of a bean or a walnut, were at the time of the operation very small collections of cancer cells which gradually grew from microscopic to macroscopic proportions, and it is reasonable to suppose that if the *x*-ray can destroy these bean-sized and walnut-sized cancer masses it could much easier have destroyed the microscopic masses of cancer cells from which they developed. I believe, therefore, that we should give this post-operative *x*-ray treatment a thorough and extended trial in our carcinoma cases, and believe that we shall considerably increase our number of permanent cures after cancer operations by this means.

The most interesting question, to my mind, in connection with the action of the *x*-ray on cancer cells is this: Would it not be possible in some way to so extend the action of this agent which has the power of destroying cancer cells under certain conditions—that is, at certain depths and cells of certain resisting powers—to a point where it can destroy them under all conditions? The fact that under certain circumstances, as Hodgkin's disease and lymphatic leukemia, the *x*-ray does produce effects on masses of cells of low resisting power at great depths, might encourage us to hope that under certain favorable conditions it might affect cancer at great depth.

Of course, if this could be accomplished our cure for carcinoma would be found. As it is to-day, the *x*-ray as a cure for carcinoma has, as we have seen, a very limited field. In answer to the last question, I have thought that the desired result might be accomplished in one of two ways, or possibly both. First, that physicists might so improve our *x*-ray apparatus that we could obtain the destructive effect on the cancer cells at all depths, and yet without too great danger to the intervening tissues, and, second, that it might be possible to so diminish the resisting power of the cancer cells by some means, as, for instance, the ligation of the arteries supplying the region, thus shutting off the blood supply, or by means of some chemical agent introduced either into the general circulation or locally injected, that even with the *x*-ray as at present developed we might obtain destructive effects at greater depths. In connection with this last proposition my mind naturally turned to iodin and arsenic as the agents which have shown evidence of power to affect deep-seated masses of new cells of low vitality, as iodin in syphilis, actinomycosis and blastomycosis, and arsenic in malignant lymphoma (Hodgkin's disease).

In working out this idea we have made some experiments to determine the effect of the *x*-ray on solutions of iodid of potash to determine whether it would produce any chemical change and set the iodin free.

The first experiment was simple, and interesting in its results. We took a solution of starch and iodid of potassium and submitted it to a 10-minute exposure of the *x*-ray, such as we used for therapeutic purposes. We had control solution under the same conditions minus the *x*-ray. It was found that the *x*-ray liberated about twice as much iodin as was liberated from the control solutions.

After all, however, the clinical test of such a therapeutic scheme is the important test, and we have employed this method of treatment, which, I think, should be called radiochemic therapy, in a number of cases. In a case of inoperable mouth carcinoma I ligated both external carotids, and placed the patient on iodid of potassium internally, and the *x*-ray. The tumor was diminished greatly in size, and almost disappeared. The patient died four months later of pyemia, and the postmortem showed a mere remnant of the original growth, and no regional or general involvement. Two of the most striking cases of benefit from this method of treatment have, however, not been in carcinoma, but in other conditions—one a case of actinomycosis of the neck, which cleared up surprisingly rapidly under the *x*-ray and iodid of potassium, and the other a tumor of the colon, already referred to, almost certainly tuberculous, which has almost disappeared under the same treatment. In our carcinoma and sarcoma cases we have combined with our *x*-ray either iodid of potassium or arsenic, and, although I have been encouraged by the results, the cases are too few and the difficulties in the way of determining the value of this combined treatment are so great that it is impossible at present to draw conclusions. I have, however, no hesitation in presenting this suggestion of composite therapy, with the hope that others may be sufficiently interested to investigate its possibilities.

It does seem plausible, however, that, given an agent which will destroy carcinoma cells and not the cells of the surrounding tissues under certain favorable conditions for its action, i. e., superficial situation and low resisting power of cancer cells, it is quite possible we may find some way of enhancing its action so as to reach cancer cells at all depths and of all degrees of resisting power and secure in this way a carcinoma cure.

In conclusion, the *x*-ray at present is indicated as a therapeutic agent:

1. In the superficial epitheliomas above described.
2. As a post-operative treatment in most of our carcinoma cases.
3. In our inoperable cases, as a justifiable piece of experimental work in the hope that this line of investigation may possibly lead to valuable results.

The dangers of the *x*-ray as a therapeutic agent are two, and these dangers should be especially pointed out to the general profession. The first danger is the possibility in all cases of producing a serious *x*-ray burn. This possibility can be reduced to a minimum by a thorough understanding of the technic, but can not be entirely done away with, as burns will occur even in the hands of experts of the greatest experience. The second danger, and the more important one, is the using of the *x*-ray in cases where it should not be used, where its use is of no benefit to the patient, where its use means valuable time scarcely have happened had a thrombophlebitis been present.

I am of the opinion that either the free germs themselves or the germ-bearing leucocytes burrowed their way through the thin membranous walls of the sinus and gave birth to the metastatic process in the liver and the clavicular joint. An interesting feature of this case not to be left unnoticed was the spontaneous cure of the hepatic abscess by rupture into the bowel.

## SYPHILIS IN THE NEGRO.*

FRANK JONES, M.D.
MEMPHIS, TENN.

With the advent of his emancipation and his citizenship the negro earned his syphilis and bequeathed it (both by acquisition and heredity) to his posterity, to such a degree that he, in a great measure, became syphilized prior to his becoming civilized. Syphilis obtains in all of its forms in its most classic type in the negro by reason of his habits, his environments, his utter indifference to the disease and his carelessness and delay in having it treated. My experience, covering a period of more than six years in a large clinic composed almost entirely of negroes, justifies me in making the statement that 75 per cent. of that class of negroes who come as patients are syphilitic (either acquired or hereditary). I could present you with a museum of Jonathan Hutchinson's teeth, bridge-shaped noses, rickets, and Parott's disease, showing the result of herditary syphilis in negro children.

### PRECOCITY.

The precocity of syphilis in the negro is striking. I have the opportunity in hospital work to see it in both ces. In the negro it is not uncommon to encounter the cre, the mucous patches, the secondary skin eruptions, the iritis, the general periostitis—especially in the sternum, the tibiæ and the costal cartilage—and the high grade of syphilitic fever existing simultaneously: fulminating syphilis or acute syphilis, if you please, overwhelming in nature, producing profound systemic infection from which all the tissues of the body suffer, especially the arteries, the heart, the kidney and the brain. It has been said by some—and I am afraid they are not acquainted with the facts—that syphilis in the negro will run its course uninfluenced by medication without deleterious results. I am not prepared to confirm this statement; syphilis leaves its marks that can be readily detected by the close observer.

### THE RELATION OF SYPHILIS AND PHTHISIS..

The prevalence of phthisis and its high mortality and its rapid course in the negro has been commented on by nearly all southern clinicians and teachers. In making a review of the subject I have not seen sufficient reasons given for its appalling mortality. I encounter it daily, but have never seen a negro with phthisis recover, it matters not what comforts he may have, what his sanitary surroundings may be, or what precautions he may take after the diagnosis has been made. Acute pneumonic phthisis is the most frequent type observed. I have often seen it run through all the stages and terminate fatally in six weeks, when the first examinatio had shown it to exist only in its incipiency.

The question might well be asked, why this high mortality and this rapid course of phthisis in the negro? Basing my reasons on my clinical observation, I think a rational conclusion can be reached as to a reason for this mortality and for this rapid course. In the majority of patients coming into the clinic with phthisis well developed, a clear history of syphilis, either recent or remote, can be found. The damage that syphilis has already wrought in the system by its effects on the blood vessels, the heart, the kidneys and the general nutrition brings about a lowered vitality, a want of resistance on the part of the patient to the invading enemy. The field is rich and ready for the entrance, cultivation and growth of the tubercle bacilli. This pre-existing or coexisting syphilis gives the right of way to this captain of the men of death, tuberculosis. Whenever a patient, whether white or black, contracts tuberculosis, having had a recent active syphilis, I always look for a rapid and fatal termination. Tuberculosis writes its seal thus on this class of patients: "All hope abandoned when I enter here." I have often seen acute syphilis and acute tuberculosis coexisting in the negro. They are the mighty monarchs which are yearly sweeping thousands of ignorant negroes from the face of the earth. Unquestionably mixed infection plays a great rôle in the production and mortality of phthisis.

### SYPHILIS OF THE PLEURA.

I often encounter insidious accumulations in the thoracic cavity where there has been no history of a previous pneumonia, pleurisy or nephritis, where, to the casual observer, the physical signs are negative and there is no symptoms that would lead one to suspect any trouble in the chest. These insidious accumulations, whether exudates or transudates, inflammatory or non-inflammatory, are marked characteristics of a recent syphilis. I wish to report the following illustrative case:

Case 1.—May 20, a male negro, aged 25, came to the clinic. He suffers with extreme pain in the abdomen, has a constant desire to go to stool, has much straining with passage of small quantities of mucus and pus; the abdomen is rigid and retracted. I found a pronounced rectitis as far up the bowel as could be seen by the speculum. To the touch the ulcers were hard and indurated. There was marked periostitis in sternum, tibiæ, radii and costal cartilages. His temperature was 102, pulse 110. He had no cough, no dyspnea, but absolute fixation of the right side. There was absence of vocal fremitus on palpation, absolute flatness anteriorly, posteriorly and laterally on percussion. Auscultation revealed absence of all respiratory sounds. Aspiration withdrew the typical straw-colored serofibrinous fluid. He gave no history, in spite of close inquiry, of a previous pneumonia or pleurisy. Two years ago, while working on a levee on the Mississippi River he contracted syphilis and took treatment of no consequence except patent medicines. His health constantly failed. Chills and fever, accompanied by this proctitis, developed. He continued with great effort at his work, but was forced to abandon it, and came to Memphis in January last. There was no ascites, enlargement of the liver, edema or albumin in the urine. Dr. Malone of the surgical staff withdrew nearly a gallon of serofibrinous fluid by aspiration.

A striking feature of these accumulations is their enormous quantity. In May, 1900, I withdrew from a male negro, who had about the same history as the one above mentioned, two gallons and a pint at one sitting, with the best results. This case serves merely to point

---

*Annual Address before Chicago Medical Society, 1903.

## SYPHILIS OF THE HEART.

What a broad field! I regret exceedingly that my limited time prevents my going into this question more than to touch on some of the salient points. The negro race, as a clinic from which to draw, could supply material out of which an ideal text-book on diseases of the heart could be written. In passing let me congratulate you, as well as the west and the medical world, on having in your city an author who in my opinion has written the most exhaustive, most comprehensive, and the most ideal text-book in any language on diseases of the heart. I refer to Dr. Robert H. Babcock.

Aortic lesions occur as frequently as mitral lesions, or even more so from the fact that syphilis so often plays a leading rôle in the production of a sclerosis from which valvular lesions at the aortic opening arise. Our text books dwell at length on inflammatory rheumatism in the production of an endocarditis from which leakage or stenosis at the mitral valve occur. In a careful perusal of such standard works as Broadbent, Sampson, Cheadle, Sibson, Gibson and Babcock, I failed to find any mention of syphilis as an etiologic factor in the causation of endocarditis. In studying heart lesions, both mitral and aortic, in the clinic, I find a clear history of syphilis more often than of inflammatory rheumatism. I believe acute syphilis produces pronounced acute endocarditis from which lesions, both valvular and muscular, may arise in all their classic stages and in their most severe forms. In this precocious type of syphilis the whole structure of the heart is very often attacked, the syphilis seeming to spend its force on this organ, nearly all the leading symptoms and physical signs of aortitis, myocarditis, endocarditis and pericarditis existing as a grand whole of cardiac symptomatology, the postmortem findings verifying the composite clinical picture. I believe that we have in these cases a true and well defined "carditis." This is a term that might be used with more significance in our text-books; but examine the standard works on the heart and you will find that the term is seldom used or mentioned. Dr. Krauss, one of the most eminent pathologists in the south, states that in his postmortems on cases in which death has occurred suddenly in these cardiac cases, where there was a history of fulminating syphilis, he often found arteritis, endarteritis, atheroma, arteriosclerosis, endocarditis, pericarditis and myocarditis existing, denoting different degrees of inflammatory and degenerative changes. Permit me to report two cases as types which are constantly coming under my observation:

CASE 2.—June 3, a male negro, aged 28, was seen at clinic. He had a temperature of 103, pulse 130; history of chancre about three months ago, throat ulcerated, squamous syphilids on all parts of body, marked periostitis in sternum, tibiæ, radii and costal cartilages. He stated in his own terms that his bones and his head pained him to such a degree that he had to walk the floor at night. The liver was tender and enlarged. He complained of having had several attacks of asthma at night the week before he came to the clinic. There was some edema of the lower extremities; dyspnea and cough were marked. He complained constantly of retrosternal pain radiating to the back, a symptom indicative of angina. On inspection the apex beat was seen to be diffused and tumultuous and displaced downward to the sixth interspace and fully three inches to the left. There was some throbbing of the carotids and jugulars. The pulse was full and bounding, and to a certain degree incompressible in the radial artery at the wrist. On auscultation there was a loud blowing systolic murmur at the apex easily heard in the axillary line and heard more distinctly behind at the inferior angle of the scapula than at the apex—in other words, all the physical signs of mitral insufficiency. At the base there was a harsh blowing systolic murmur. From the history, the physical signs and the symptoms I made a diagnosis of a general aortitis and mitral insufficiency. The question arises, was there not an aortitis primarily extending down into the endocardium, from this endocarditis and sclerosis, the mitral leakage following as a consequence. In spite of the closest inquiry he denied ever having had inflammatory rheumatism. The prognosis in this case is grave, possibly my assistant will sign his death certificate before I return to Memphis.

CASE 3.—May 28, I saw a negro woman, aged 26, occupation cook. She married three years ago, and has had three miscarriages, at three, four and seven months respectively. About a year ago she left her husband because he gave her, to use her own words, "the bad disease." Judging from the history she gave me, the attack of syphilis she had was acute and violent. She gave no history whatever of ever having had inflammatory rheumatism. She had a temperature of 105, pulse 140. A few days previous to my seeing her she stated that while washing some clothes she was attacked by a most violent chill. I found the liver enormously enlarged and very tender on palpation. Periostitis in sternum and tibiæ was so pronounced that she would cry out with pain whenever I attempted to palpate or percuss in these regions. The conjunctivæ were slightly jaundiced, tongue large, heavily coated and flabby, rigors and profuse sweats were pronounced. She was semidelirious. There was no edema in the lower extremities, no albumin in the urine, but all kinds of casts in abundance. She stated that she had been treated by a quack a few months ago for dysentery, but on examining the rectum I found a proctitis so pronounced that you might say that stricture of the rectum was in the creative stage. The heart action was tumultuous, the apex beat so bounding that you could see it several feet from the bed. On auscultation there was a blowing murmur at the apex, systolic in time, heard in the axilla, indicative of mitral insufficiency, also a spinning top diastolic murmur at the base, transmitted up and down the sternum. I gave as a diagnosis, malignant endocarditis engrafted on a syphilitic aortitis and myocarditis. While attempting to take her medicine she died, on the morning of June 12. The family would not consent to autopsy.

## SYPHILIS OF THE RECTUM.

In conclusion I wish to call your attention to syphilis in the rectum. I have recorded 48 cases of stricture of the rectum, of which 47 were found in negro women, and the other in an old negro man. This last was malignant. One was tuberculous in a negro woman with acute pneumonic phthisis; 46 were undoubtedly syphilitic; the youngest patient was a prostitute 17 years of age. You will note that all these strictures except one were found in the female. I do not think that our text-books on diseases of the rectum are as clear on this subject as they should be. They do not dwell sufficiently on the subject. of pathology. I believe if the general practitioner was a little more careful in his examinations where patients present themselves complaining of pronouncd constipation he would find more strictures of the rectum in his practice. Not long ago I read a paper on this subject before the Tri-State Medical Association of Arkansas, Mississippi and Tennessee. A leading physician and gynecologist of my city, Ten- who has been practicing for twenty-seven years, remarked to me after having read my paper that he had never seen but one case of stricture of the rectum and that was while he was an interne in Bellevue Hospital. It can be readily seen why stricture of the rectum, syphilitic in nature, should occur so much oftener in the female than in the male. The chancre on the posterior wall of the vagina can from contact easily infect the rectum. In these chancres there is often mixed infection, namely, syphilis and gonorrhea. Authorities state that the stricture of the rectum is an expression and a condition, the results of tertiary syphilis. In the analysis of my cases I have found that the proctitis from which the stricture resulted in a majority of the cases developed early along with the secondary eruption.

At Saratoga, in the discussion on syphilis, Dr. Osler used these words: "He who knows syphilis well, knows it all." I will not put it so strongly, but will say: "He who knows syphilis well, is fairly well equipped to practice internal medicine."

# RAPIDLY GROWING SARCOMA OF THE FEMUR.

## REPORT OF A CASE: DISARTICULATION AT THE HIP JOINT; RECOVERY.*

C. M. NICHOLSON, M.D.

Professor of Surgical Anatomy and Clinical Surgery, Medical Department St. Louis University; Attending Surgeon Rebekah Hospital and Grand Avenue Dispensary; Consulting Surgeon Mount St. Rose Hospital; Clinical Surgeon St. Louis City Hospital.

ST. LOUIS.

Sarcomata arising from the femur, the bone most liable to become affected, may be grouped according to point of origin into central and peripheral, the first arising from the osteoblastic layer lining the medullary canal and the second from the osteoblastic layer separating the periosteum from the bone. The first group is usually a giant-celled or myeloid tumor, though the spindle or round cell may be found. The second group is usually round- or spindle-celled sarcoma (never myeloid), though mixed, round and giant cells are not uncommon. The peripheral are more painful, occur earlier in life, are more malignant and pulsation is seldom observed.

When growing near the middle of the shaft, the peripheral variety may be restricted to a portion of the circumference or entirely surround it, producing a fusiform swelling. In such specimens the shaft of the bone traverses the tumor and may, beyond a slight amount of erosin, be unaffected by it. In these cases, however, the medulla may become infected by the cells making their way along the haversian canals.

The second group is more liable to the various metamorphoses and degenerations affecting sarcoma generally, and is more liable to calcification and ossification than central tumors. In some instances the affected bone is greatly thickened in the parts related to the tumor.

The extensive ossification associated with periosteal sarcoma is fully understood when we recognize the fact that bone making is the essential feature of the periosteum.

Giant-celled sarcomata are usually of slow growth and involve the lower end of the femur; they are generally regular, spherical, and more or less firm. Owing to the resistance offered by the articular cartilage, neighboring joints are seldom involved until very late in the disease.

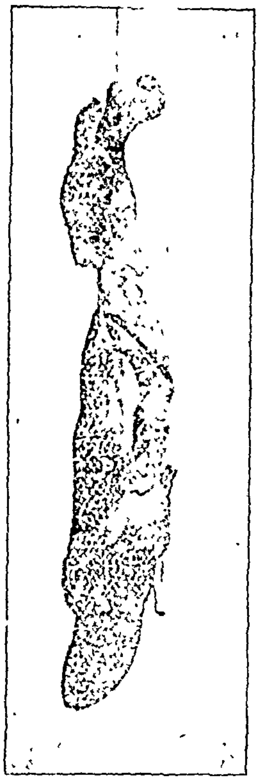
Gross, in reviewing 165 cases of sarcoma of the long bones, found 42 per cent. giant-celled tumors, 21 per cent. spindle-celled osteoid sarcoma, 7.5 per cent. spindle-celled, 7 per cent. round-celled and 4 per cent. pure periosteal spindle-celled sarcoma.

In all varieties the growth attacks the lower epiphyses most frequently. Lymphatic involvement is very unusual, though Loeffler states that it occurs in 13 per cent. of the peripheral sarcoma.

As a rule, where the inguinal and femoral glands are enlarged it is due to other causes, microscopic examination showing no sarcomatous changes. Tumors occupying the center of the diaphysis in growing cause expansion of the osseous boundaries, producing a round- or spindle-shaped swelling, causing the bone to become so thin as to be broken on the slightest exertion. Not infrequently the first symptom which directs the patient to the surgeon is fracture of the bone through the tumor, which, though rare in childhood, is frequent in young adults. It occurs in about 60 per cent. of the cases.

The prognosis of sarcoma is bad; three-fourths are of the periosteal, the most malignant variety. Bland Sutton says the duration of life rarely exceeds eighteen months.

Bork collected 111 cases of disarticulation of the hip joint for sarcoma of the femur operated on in the clinics of Europe, none of which could have been considered cured. Jeckel reported 35 cases operated on in the clinics of König and Bran, 4 cases of which were considered as having completely recovered. He reports having found 6 cases in the literature, more than four years having elapsed in each case without evidence of return. These cases were operated on by Holmes, Rose, Kramer, Weisenger and Von Mikulicz.



Photograph showing the growth occupying the middle third posterior aspect of femur.

### NARRATION OF CASE.

The little boy which I present is James Paul, an American, age 8 years, who presented himself during March, 1901, suffering from pain about the middle of the right thigh.

Family history negative. Has had all the diseases of childhood, though apparently well for two years prior to five weeks ago. He suddenly complained of pain about the middle third of the right thigh; severe, especially at night, of a dull aching character, which constantly increased for several days; then a physician was called, whose treatment consisted of rest in bed, application of heat and administration of opium.

Examination showed the patient to be fairly well nourished, though during the preceding five weeks he had lost 15 pounds. Temperature 103, examination of the urine negative. The chest, abdomen and lower limbs were apparently normal except for a fullness of the lower third of the right thigh.

The measure of the knees across the center of the patellas showed no variation in size, but the right thigh at the junction of the middle and lower third was 3 cm. larger than the left. The knee was flexed and the lower part of the thigh exceedingly sensitive on pressure.

Fluctuation could be detected and a diagnosis of abscess was made. An incision about 5 inches in length, the lower end of which was just above the knee joint, was made, and between six and eight ounces of pus escaped. There was found much enlargement of the middle third of the femur, and a posterior projection was removed and subjected to a microscopic examination. It proved to be a small round-celled sarcoma, and disarticulation at the hip joint was recommended.

The following day a straight incision about six inches in length directly over the center of the great trochanter was made parallel with the long axis of the limb, the circumflex arteries ligated, the trochanteric muscular attachment severed close to the bone, and the capsular ligament was divided transversely at the upper and posterior aspects. The remaining portion of the capsular ligament was severed when the thigh was brought into position of slight flexion. The head of the bone was dislocated on the dorsum of the ilium and the trochanter minor and upper parts of the femur cleansed. The dislocation was then reduced, Wyeth pins inserted, an Esmarch applied and a curved incision made six inches below the great trochanter, the vessels ligated, skin flaps made and thigh removed.

---

* Paper read, patient and specimen presented at the forty-sixth annual meeting of the Missouri State Medical Association.

Just thirty-six minutes after the operation was begun the dressings were applied. The patient made a rapid recovery, the wound healing throughout by primary union; he was discharged three weeks later.

The tumor was examined by Dr. B. Meade Bolton, director of the Pathological Laboratory of the Medical Department St. Louis University, whose report is as follows:

"The tumor occupies nearly all of the posterior aspect of the middle third of the femur. It apparently arises from the osteoblastic layer separating the periosteum from the bone. A conical spur of bone, with the base measuring about five square centimeters, attached to the femur, arising at the junction of the lower and middle third. This spur is somewhat spongy, and extends upward and backward for about 10 cm. The bone around the base is eroded, and the posterior face of the femur is also eroded superficially from the base of the osteoma down to the popliteal plane. Firmly attached to this spur of bone, or rather blending into it without a sharp demarcation, is a fleshy mass, which was found to consist on examination of microscopic sections of embryonic connective tissue cells. These were mostly small round cells, but large round cells and spindle cells were also more or less abundant. From the clinical history and microscopic findings the tumor must be regarded as a small round-celled sarcoma, containing also large round cells and spindle cells. The medullary canal and bone marrow are apparently normal."

His condition has steadily improved and there is absolutely no evidence of return. During the last twelve months he has gained 22 pounds.

2900 Washington Avenue.

## Clinical Report.

# A CASE OF MARJOLIN'S ULCER.

HARRY M. SHERMAN, A.M., M.D.
Professor of Surgery, Medical Department, University of California; Surgeon to St. Luke's Hospital; Orthopedic Surgeon to the Children's Hospital, San Francisco.
SAN FRANCISCO.

*History.*—In the winter of 1901-2 I saw an elderly gentleman who for over twenty-five years had had an ulcer with bony floor on the back of the right ankle. Originally there had been an open comminuted fracture of the tibia, astragalus and os calcis; this had become infected, there had been necrosis of the bone and exfoliation of fragments, but the ulcer had never healed and some bone had always remained exposed. All this time the man had lived an active business life.

*Commencement of the Ulcer.*—He applied to me because of an increase in the size of the ulcer and considerable pain. I suggested the removal of the dead and infected tissue, to be followed by rest, to permit healing. This was accepted, and the operation was done under cocainization of the sciatic nerve. For a time things went well and healing was in progress, but in about two months the pain returned and the wound began to ulcerate again, and this was most marked at the lower end, where a pit of considerable size was formed in the os calcis.

At this very time there grew up, out of the middle of the ulcer, a tuberous mass, fully 1.5 cm. across and equally as high or higher. From the first it was differentiated from the surrounding ulcerating surface; it bled easily, and was without sensation. Clinically, I thought it a sarcoma, as did two other surgeons, a physician and a pathologist. The latter was not wholly convinced, for he had examined portions of the mass, had found it to be only granulation tissue and could not agree with the clinical opinion, but he agreed with all of us that the leg should be removed.

*Operation.*—This was done by amputation through the upper third of the leg, for the mass grew from the os calcis and not from the tibia. In another individual we might have been induced to go higher for the amputation, but a thigh amputation was considered too much risk for this old man who had sclerotic arteries and a bad heart. The operation was done under spinal cocainization. Healing was uneventful, and in due time an artificial leg was put on and the patient returned to his business. The amputated leg was sent to the laboratory, examined and sketched and portions of the margin of the ulcer sectioned and examined, but nothing was found.

*Recurrence.*—In about four months a tumor mass appeared in the popliteal space and was promptly removed under sciatic cocainization. The wound healed, but other masses soon appeared and replaced the first, pain supervened, later came ulceration and the whole clinical picture of extensive secondary epithelioma. Epithelioma had been the laboratory report from the first popliteal mass, and further search of the margin of the ulcer in the heel showed that at the lowest part, and only there, there was a primary epithelioma and that the lesion was a "Marjolin's ulcer."

*Comments.*—The case is reported because of its rarity. Da Costa[1] reported two cases and discussed the subject. He calls special attention to the changes which occur when a chronic indolent ulcer takes on malignant character; the beginning of pain and tenderness, the increase in the discharge, which also becomes foul, and the special induration and later ulceration of one part of the ulcer edge. None of these characteristics were present in the ulcer when I first saw it. Henry R. Wharton, in discussing Da Costa's paper, referred to four cases. In two the injury which resulted in the ulcer had been received in the War of the Rebellion and the cases seen only in recent years. In the third case the ulcer had existed thirty-eight years, and in the fourth fifty-eight years.

In the present instance the diagnosis was not made until the secondary growth made it for us. Even then the clinical expectation was that the laboratory report would be sarcoma because of the confusion arising from the curious mass of exuberant granulation tissue. A second study of the ulcer's margins showed that the epithelioma occupied no more than one-eighth of the periphery; that there was no induration at that point and no tumor; only, in fact, a little crater in the edge of the floor of the ulcer dipping down into the subjacent bone.

How long the epithelioma had been in existence I do not know; certainly it antedated the first operation, for the ulcer was not "chronic" after that date, and quite long enough, too, for a metastasis to occur before the amputation. At the same time this case, with those quoted, goes to show that it takes a very long time for irritation to inaugurate a malignant growth in a chronic ulcer.

---

**Diabetes in Children.**—Berkenheim announces from Kissel's clinic at Moscow that diabetes is not so rare among children as generally supposed. Bogoraz collected 500 cases in 1899. Berkenheim describes in detail the 2 cases observed in his experience, both terminating fatally. The mortality in Bogoraz's statistics was 90 per cent., and 13 of the children were under 1 year of age; 92 between 1 and 5; 147 between 5 and 10, and 234 between 10 and 15. The course of the diabetes is much more rapid than in adults, and is characterized by large output of sugar with little urea. Incontinence of urine is an important symptom, and any intercurrent or complicating infection materially reduces the amount of sugar in the urine. Edema is much less frequently observed than in adults. His communication is published in the *Klin.-therapeutische Wochenschrift*, X, No. 28, 1903.

## THE NEURONE DOCTRINE.

When, in 1891, Professor Waldeyer of Berlin brought together the histologic, embryologic and pathologic data regarding the unit in the nervous system and called that unit the "neurone," the term met with widespread acceptance. It served to crystallize, as it were, in a single expression, the qualities of the nerve unit which had been detected by the developmental studies of His, the pathologic researches of Ford and von Monakow and the morphologic investigations of Ramon y Cajal.

Since the term was introduced, however, further facts regarding the histology and physiology of the nervous system have been discovered. Our knowledge of the existence of delicate fibrillæ within the nerve cell protoplasm has been extended by the exquisite methods of Apathy and Bethe, the existence and distribution of those delicate particles known as "neurosomes" have been demonstrated by Held, the networks of Golgi and Bethe in the periphery of the nerve-cell body and the dendrites have been made the objects of special study, and a number of researches have dealt with the interesting question of the exact character of the relations of one neurone with another in various parts of the nervous system.

When Waldeyer wrote he was of the opinion that the nerve units or neurones possessed anatomically and physiologically a relatively complete independence of one another; he supposed that the terminals of one neurone entered only into contact relation with the cell bodies and dendrites of other neurones, but he took especial pains to point out that were this not true and were the interneuronal relations more intimate than that of mere contact, the doctrine of nerve units or neurones could still be held.

Two bitter antagonists of the neurone doctrine have been waging war against it in Germany. Nissl of Heidelberg and Bethe of Strassburg have fought it vigorously, each declaring that the conception of the nerve units is untenable and out of accord with known histologic and physiologic facts. On the other hand, the neurone doctrine, in spite of all objections raised against it, has been strongly supported by Barker in America, by Waldeyer, von Lenhossek, Verworn and Ziehen in Germany, by Mott in England, by Ramon y Cajal in Spain, and by Van Gehuchten in Belgium. Some of these authors, it is true, are unsettled as to the exact character of interneuronal relations which exist, and especially as regards the so-called contact relation, but this question they look on as only one phase of the great problem, far less important than the main anatomic, physiologic and pathologic facts on which the doctrine as a whole is based.

One of the strongest champions of the neurone doctrine in its totality, even to the reassertion of the contact connection as the only interneuronal relation, is the distinguished neurologist of Madrid, Professor Ramon y Cajal. In a recent article,[1] this investigator not only supports the neurone doctrine and the idea of interneuronal relation by contact, but attacks the very foundation of Bethe's and Nissl's objections. He declares that Bethe has mistaken a pericellular precipitate for a nerve network, denies any continuity between the terminals of axons and collaterals and the intraprotoplasmic neurofibrils of the cells on which they end and urges that Bethe's method is unsuited for the solution of the problems on which he works. The article is a strong arraignment of the tenets of the anti-neuronists, and while we can not go into all its details here, we would call to it the attention of those of our readers who are interested in the controversy.

## TUBERCULOSIS IN PRISONS.

It is encouraging to find that the attention of prison authorities and reformers is at last turning to the question of tuberculosis in prisons. The State of New York has led the way in providing the first isolation wards for the treatment of tuberculous prisoners, and the fifty-eighth annual report of the New York Prison Association discusses this question at some length. Conditions in the penitentiaries of this state certainly called for some vigorous action. Sing Sing is described as a "nest of tuberculosis," and Auburn is said to be little better. The third penitentiary is at Dannemora in the Adirondacks, and has a climate which has been proved to be favorable for the treatment of tuberculosis.

For some time it has been the custom to transfer tuberculous prisoners from Auburn and Sing Sing to Dannemora. In the ten-year period, beginning with 1891, 796 such cases have been thus transferred. During the first five years the total number of deaths from tuberculous diseases was: Sing Sing, 86; Auburn, 133; Dannemora, 34; total, 253. Up to the end of this first period little attention had been paid to the subject of tuberculosis in prisons and institutions, beyond the transferring of many to Dannemora, but during the succeeding five years far more systematic and effective methods of treatment and isolation have been adopted with the following results: The number of deaths in Sing Sing was 23; Auburn, 27; Dannemora, 22; a total of 72 deaths, which means an improvement of 71 per cent. in the second period over the first. Dannemora now has a new ward for tuberculous patients, although its accommodations are still far from adequate. It has an exercise court, and the prisoners are kept in the open air as much as is consistent with prison environment.

---

[1] Consideraciones Criticas Sobre la Teoria de A. Bethe Acerca de la Estructura y Conexiones de las Celulas Nerviosas. Trabajos del Lab. d. investig. biol. de la Univ. de Madrid, t. II, 1903, pp. 101-128.

Most American prisons were built before the infectious nature of tuberculosis was a generally accepted fact, and it is doubtful if any great prison has yet been built with an intelligent purpose to protect prisoners from tuberculosis. At any rate, it must be admitted that by far the greater number of penitentiaries serve as well-planned incubators for the cultivation of tubercle bacilli.

In Joliet, Ill., there seems to be a typical prison of this sort. Its last biennial report states that on account of the overcrowding it is necessary to place two prisoners in many cells whose dimensions are seven by seven by four feet, and continues thus:

> When one thinks of two men spending never less than fourteen hours each day during six days of the week, and on the seventh day nearly twenty-one hours, in a space so reduced, and with a slop bucket in the cell for their use in responding to calls of Nature, which no care can prevent from being offensive and pestilential in every sense of the word, he is compelled to ask what excuse the great State of Illinois can offer for compelling the management of this penitentiary to so deal with men who are required by law to serve sentences here. . . . .
>
> One visit to the cellhouses during the night time, a few breaths of the atmosphere coming from them, is all that is necessary to convince the most skeptical that the half has not been told by us, and we here and now enter our solemn protest against the continuance of such a system of herding men together to the detriment of their physical and moral natures.

The spread of tuberculosis must be favored by such conditions, and it seems almost impossible to accept as conclusive the optimistic health statistics in this report. We suspect that the practice of paroling prisoners in the last stages of consumption in order that they may die at home (a practice against which we have nothing to say), exists at Joliet, as in some other prisons, and it is largely responsible for the low death rate. The other Illinois penitentiary, at Chester, makes no such favorable showing. Fifty-six per cent. of the total number of deaths at Chester were from tuberculosis, an increase of 21 per cent. over the preceding two years, and the last report makes a strong appeal for suitable provision for the isolation and care of tuberculous prisoners.

Of course, we can not expect from the most favorable prison conditions as good results as from the usual sanatoria, where patients have their freedom and a more generous dietary than will be supplied in prisons. Yet in view of the increased knowledge as to the physical conditions necessary for the prevention and care of tuberculosis, and in view of the fact that the prison patient can be absolutely controlled by his physicians, we may yet hope that before too long tuberculosis may be stricken from the list of diseases contracted in prison.

## THE CAUSE OF SCARLET FEVER.

From time to time announcements are made to the effect that the cause of scarlet fever has been discovered, but so far none of these assertions has received general acceptance. Even the assertion that scarlet fever is a streptococcus disease has not proved itself successful, in spite of the almost constant association of local and general streptococcus infections at least in severe cases of scarlet fever, principally because the streptococci isolated from cases of scarlet fever do not differ from the ordinary streptococci, and because of the further fact that while one attack of scarlet fever, be it ever so mild, confers a permanent immunity to subsequent attacks; this unfortunately does not hold true in regard to the various forms of streptococcus infection with which we are familiar.

It is significant, too, that while the recent studies of smallpox show that more or less extensive streptococcus infection occurs in practically every severe and fatal case of this disease, yet we do not think that any one would venture the assertion that smallpox is a streptococcus disease. In other words, there seems to be an analogous susceptibility to secondary streptococcus invasion in both scarlet fever and smallpox, a susceptibility that on account of the ubiquity of streptococci only too often is fraught with the greatest dangers to the patient. Concerning the assertions that certain bacilli and cocci are the cause of scarlet fever, we believe that the less said the better. Some of these assertions have been made the object of extensive exploitation in certain quarters that savor more of self-glorification than of true scientific spirit.

The description by Mallory of certain bodies in the skin of four cases of scarlet fever dying within forty-eight hours of the appearance of the eruption, bodies which he believes are protozoa, may be said to carry the investigation in the etiology of scarlatina into a new field. In another column of this number we give the principal points in Mallory's paper. It will be seen that the evidence of the nature of these bodies so far rests wholly on morphologic grounds. While it is true that it may be "difficult to explain these bodies as artefacts or as degenerations," yet it seems only fair to emphasize, first, that the protozoan, or speaking broadly, organismal nature of these bodies has not been proven definitely; and, second, that whatever their nature, their etiologic relation to scarlet fever is as yet equally lacking in definite proof, a fact that Mallory himself, though personally convinced of their protozoan nature, is far from asserting as established—a conservative attitude that must appeal to all who are familiar with the tremendous difficulties at present in the way of this form of investigation. The most that can be said now is that the finding of these bodies, which no doubt is largely owing to the great technical skill of their discoverer, and the interpretation as protozoa by an investigator of Mallory's healthy conservatism, give us reason to regard as not unreasonable the hope that eventually this may prove the first step in unveiling the hitherto so well-guarded cause of scarlet fever.

### TRADES UNIONISM AMONG HOSPITAL ATTENDANTS.

In a communication published elsewhere in this issue, a state of affairs is noticed that certainly deserves the attention of the profession, as it bears on a medical question, and a very important one—the care of the helpless insane. In the Cook County Asylum for the Insane, at Dunning, near Chicago, a labor union has been formed among the attendants and employes which is now demanding an increase of wages and a uniform scale. The former item is one for the taxpayers to consider. It seems to be a fact, however, that this institution has paid the highest wages with probably the worst service of any insane asylum in the State of Illinois, not to speak of other states where the wages are still lower.

A uniform scale, however, is a general leveling down and would make it impossible to obtain adequate service. Moreover, the mere organization of a union, taking out of the hands of the officials of the institution to a large extent the discipline and control of the employes, is a matter that should be protested against most emphatically by everyone who has the welfare of the helpless charges at heart. It is only at long and rare intervals that the institution has had a competent physician at its head. Some years ago an alienist of reputation held the place for a short time, but was finally ousted by the powers that were, but the good fight he made assisted in sending a number to the penitentiary for varying terms of public service. At the present time the institution has a man at its head who has reputation and experience, and it was hoped that he would have the free hand that is absolutely necessary to carry out the needed reforms. We do not think that the board of county commissioners is corrupt, as was the case in the former instance, but if it has not the backbone to resist the demands that are made on it by these outside organizations, it will be almost equally guilty, though unfortunately not equally punishable. The position of attendant in a hospital for the insane is not a hard one; the hours are long, but the work is interesting and the employment is considered very desirable by good attendants who have interest in their work. There is comparatively little risk, and much chance for personal improvement for individuals desiring it. In times past the positions at Dunning have been counted among the minor political plums and sought for accordingly. Therefore, the plea of hardships, etc., is a fictitious one, and should not be seriously regarded. Dr. Podstata shows that at the present time the pay is far above that of similar institutions. The question now is whether the insane of Cook County are to be under the control of the walking delegate or the skilled medical superintendent, who must have full control to regulate the 'discipline of the institution for the best interests of those under his charge.'

Not long ago a labor organization, whose oath and obligation required fealty to it above all other obligations, religious and political, attempted to dictate to the United States Government and made a weak-kneed official yield, but ran against a rock a little later. Still more recently the organization of the fire department of the City of Chicago had to be promptly sat on by the city authorities. A similar movement which has made greater progress and become more firmly established in this public institution deserves the same treatment. No man entering public service should owe allegiance to any outside authority or organization; a labor-union "pull" and a political "pull" should be alike excluded. We trust the profession will take this matter up; otherwise we may see the expected reforms in the Cook County institutions defeated and the establishments relegated back to their former unenviable notoriety.

### THE REPORT OF THE FRENCH YELLOW-FEVER COMMISSION.

In 1901 the French Government sent a commission to Rio Janeiro to investigate yellow fever. This commission was composed of MM. Marchant, Salimbeni and Simond, and it was placed under the scientific direction of the Pasteur Institute in Paris. The report[1] of this commission makes most interesting reading for American physicians, because it contains unequivocal confirmation of the epochal investigations of Reed, Carroll and Agramonte in regard to the mode of infection and the deductions therefrom as to prophylaxis—deductions of paramount importance, and the soundness of which have been demonstrated already in the most brilliant manner by the great work of Gorgas in the sanitary rejuvenation of Havana. The work of the French commission is noteworthy on account of the co-operation of over twenty men who nobly subjected themselves to the risks of the inoculations. Yellow fever is now a controllable disease, to a large extent robbed of its terrors and deprived of its former destructive effects on commerce.

Of the many details established by the French commission, special mention may be made of the following: The serum of yellow-fever patients is virulent up to the third day of the disease, but not later, and 0.1 c.c. (one-tenth) of virulent serum suffices to produce the disease when injected subcutaneously. The virus traverses the Chamberland filter-bougie F without dilution, but not the bougie B of the same system. This is in accord with the observation of Reed and his colleagues, who showed that the virus passes through Berkefeld filters. Hence the yellow-fever germ, whatever its nature, must be classed with the so-called invisible microorganisms. Heating the serum to 55 C. for five minutes renders it harmless, and the injection of heated serum produces a relative immunity which becomes complete on the additional injection of a small quantity of virulent serum. The serum of convalescents has distinct preventive and therapeutic properties. The French investigators confirm to the letter the assertions of Reed, Carroll and Agramonte that yellow fever is produced by the sting of *Stegomyia fasciata* infected by biting yellow-fever patients. During the first three days of the disease, the infected mosquito becomes dangerous at an interval of at least twelve days after sucking the virulent blood. As in Cuba so in the region of Rio Janeiro, no other mosquito but *Stegomyia fasciata* plays any part in the transmission of yellow fever, and as the disease under natural conditions does not appear to be transmissible in any other way, the prophylaxis of yellow fever rests wholly on measures that prevent *Stegomyia fasciata* from biting yellow-fever patients and healthy persons.

---

[1] Annales de l'Institute Pasteur, November, 1903.

It is important to note further that *Stegomyia fasciata* is commonly inhabited by various parasites—molds, yeasts and protozoa—none of which, however, appears to have anything to do with the transmission of yellow fever. The French investigators studied this phase of the problem thoroughly, and their results seem to support the criticisms of Carroll[2] that the alleged discovery by Parker, Beyer and Pothier of the protozoan cause of yellow fever lacks foundation.

### CREDIT DUE AMERICAN INVESTIGATORS.

Apropos to the above comments on the Report of the French Yellow-Fever Commission, we recall that a daily paper a few days ago commented in a somewhat disparaging manner on the fact that so far no American scientist or writer has been made the recipient of a Nobel prize. Thus it is stated that "it is strange that with all the facilities for original research this country now has they have not been utilized to better advantage." We believe that a knowledge of the work of Reed and his coworkers in yellow fever and of its far-reaching consequences is fully sufficient to convince any intelligent person of the injustice of this reflection on the achievements in recent years of scientific medicine in America. It is far from our intention to question the judgment and the fairness of the committee in charge of the distribution of the Nobel prizes—its members undoubtedly have difficulties of their own—but no one will dispute, for a moment, the title of the medical officers of the U. S. Army, led by the lamented Reed, to the fullest recognition and reward that it is within the power of human gratitude to give, for their work in solving the etiologic riddle of yellow fever. The untimely death of Walter Reed has placed him beyond the reach of personal reward at the hands of his fellowmen, but his achievements, though uncrowned by prizes and honors, always will remain one of the chief glories of American medicine.

### TAX ON AVOIRDUPOIS.

A Swedish municipality, it is said, has established a tax on its overweight citizens; all above normal weight must pay a graded tax according to their avoirdupois. Great weight will be a luxury in that community. It is said that the scheme is not for revenue, as might be supposed, but in the interest of good health and good morals and dietary reform. The reformers think that their people eat too much, and that both economy and health will be favored by the tax. Inasmuch as some poor people gain in weight not by drinking beer or by taking too much carbohydrates or otherwise, but suffer from an unfortunate peculiarity of metabolism, this tax seems a little unfair. Nevertheless, if those who suffer from adiposis dolorosa and similar diseases could be exempt from the tax, it might be a good thing. A little more exercise and work would not only bring down the extra avoirdupois, but would also add to the health of the individual.

### THE GOSPEL OF DIRT AGAIN.

The newspapers at the present time are discussing[1] the utterances of an aberrant eclectic whose new gospel of dirt was noticed in THE JOURNAL on a former occasion. He has apparently still further emphasized his former opinions, and states the unfortunate results of bathing, illustrating it by the case of a poor Eskimo who came to this country and took a bath, dying almost immediately of pneumonia. The gentleman evidently does not know that Eskimos do bathe, and that while their methods of cleansing themselves are not very attractive, they are eminently effective, and the fact is that the Eskimo is as proof against pneumonia due to bathing as any white man who indulges in it habitually. It should be said in this connection that this gospel of dirt is being credited as having been given out before the Chicago Medical Society, a body which would certainly have repudiated the man and his opinions alike. It was not the Chicago Medical Society, but an eclectic society.

### ILLEGAL ADVERTISEMENTS IN IOWA.

A Michigan law making revocable the license of any physician publishing illegitimate advertisements in the newspapers has been commented on already in THE JOURNAL. The law in Iowa would be still more effective if it were only enforced. In the *Iowa Medical Journal*, December 15, Dr. H. B. Young calls attention to Section 4954 of the Iowa statute, which reads: "Whoever prints or publishes, or causes to be printed or published, in any newspaper published or circulated in this state, any advertisement of medicine, drug, nostrum or apparatus for the cure of private or venereal disease, or shall circulate or distribute any newspaper containing such an advertisement or notice, shall be guilty of a misdemeanor, and shall be fined not more than $1,000 nor less than $50, or shall be imprisoned in the county jail not more than one year, or both." Under this statute Iowa ought to be free from objectionable advertisements of the character mentioned, but we fear that the law is very seldom enforced. It is unfortunate, moreover, that the statute does not cover other objectionable advertisements that are inserted in the newspapers that are just as evil in their origin and tendencies as those specified. It would probably not be difficult to have such added by amendment. Young suggests to the members of the medical profession that they do their part in aiding in the enforcement of the statute as it now exists. The editor of the *Iowa Medical Journal* says that the main thing necessary will be for the committee on public health and legislation in each county society to call the attention of the offending parties to this law, and to stimulate the county attorney, when necessary, to take action.

---

[2] THE JOURNAL, Nov. 28, 1903, p. 1341.

[1] In this connection see "Miscellany" in this issue, p. 47.

### TECHNIC IN TREATMENT OF ALCOHOLISM.

There has always been a difference of opinion as to the proper management of delirum tremens, and even in the text-books there is a variety of recommendations as to the immediate or the gradual withdrawal of alcohol. In a recent paper[1] Dr. J. F. Kelly, assistant physician at the Cleveland State Hospital, states that the results of his experience indicate that the shutting off of alcohol at once is a dangerous procedure and that alcoholic drinks must be gradually reduced. The question whether delirium tremens is due to abstinence from alcohol is answered, he says, in a spirit of inquiry rather than of assertion in the affirmative. We are well aware that popular notions attribute delirium tremens to the sudden abstinence from alcohol in a habitual drinker, but medical opinion has rather been to the contrary. It is the general experience of the profession that delirium tremens is the result of a continued excess or exacerbation of the drinking habit. Cases that have been seen of the actual delirium tremens following sudden cessation of alcohol must at least have been rare in medical experience, still extreme nervous disturbances and actual maniacal attacks have been reported as the result of the sudden cessation of alcohol, but exceptional rather than as a rule. Dr. Kelly states that he has frequently seen patients in whom delirium tremens developed from sudden withdrawal of the alcoholic drink, while with gradual cessation of the alcohol no such symptoms were observed. It is not improbable that alcohol, like other poisons to which the system becomes to a degree habituated, causes a condition from which more or less disorder results when the customary stimulus is withdrawn; but the danger of such an event would appear to be rather less than after the sudden withdrawal of morphin. The question is worthy of further investigation. We may have to give qualified statements as to the advisability of cutting off alcoholic drinks, at least in some cases, but ultimate withdrawal is, of course, necessary. With the judicious use of nerve stimulants complete withdrawal may be the best in skilled hands.

### THE ABANDONMENT OF THE WORLD'S CONGRESS OF MEDICINE.

We have received a copy of a pamphlet addressed to the medical profession of the United States and issued by the committee on organization of the World's Congress of Medicine which was to have been held in St. Louis in September, 1904, under the auspices of the Universal Exposition Company, in which is given a history of the creation of the committee, an account of the work done and the causes which led up to the resignation of the committee and the abandonment of the congress. The committee, consisting of Drs. W. E. Fischel, L. H. Laidley, F. J. Lutz, W. G. Moore and H. Tuholski, all of St. Louis, is deserving of the highest praise for the work it did, and commendation for resigning and giving up the congress when it found that it was to be subordinate to and dominated by the management of another congress, which had no direct interest in the success of the medical congress. The general plan of the proposed medical congress, as outlined by the committee, and on which an enormous amount of preliminary work had already been done, would have resulted in one essentially different from the international congresses as heretofore held. This is the principal reason why it is to be regretted that it could not be carried out. As we understand it, the main cause of the abandonment of the medical congress was that a Congress of Arts and Science had been arranged, which is to have departments covering practically all of medicine and surgery; consequently, a conflict might have been expected. Arrangements, however, were proposed by which the officers of the Congress of Arts and Science were to co-operate with those of the World's Congress of Medicine, the latter to be held a week later than the former; and all papers, etc., relating to medicine in the subdivisions of Department 15 and all of Department 18 of the Congress of Arts and Science were to be reserved for and transferred to the medical congress. It is a pity that this arrangement could not have been carried through. Meanwhile the national advisory council of the World's Congress of Medicine, a body created to aid the committee on organization and composed of representative medical men of the United States, at its last meeting passed a resolution in which it decided to co-operate in making the Congress of Arts and Science a success.

## Medical News.

### COLORADO.

**November Deaths.**—During November 719 deaths were reported, an annual death-rate of 15.15 per 1,000. Diphtheria caused 15 deaths; scarlet fever 6, and typhoid fever 44.

**Hospital Wing Soon Opened.**—The new wing of St. Luke's Hospital, Denver, and the Katherine Hallett Home for Nurses are almost completed, and will soon be ready for dedication.

**Diphtheria and Antitoxin.**—For the six years before the discovery of antitoxin the mortality percentage of diphtheria in Denver was 36.4. For the eight years following its discovery the mortality percentage was 9.97.

**Officers Elected.**—The newly elected officers of the Otero County Medical Society are: Dr. James F. Kearns, La Junta, president; Dr. Carl Myer, Rocky Ford, vice-president; Dr. E. Gard Edwards, La Junta, secretary, and Dr. Albert L. Stubbs, La Junta, treasurer.

**Morbidity.**—During November, 100 cases of diphtheria, 151 of scarlet fever, 60 of smallpox and 321 of typhoid fever were reported; an increase of 56 cases of scarlet fever and 21 cases of smallpox, and a decrease of 5 cases of diphtheria and 121 cases of typhoid fever as compared with the previous month.

### DELAWARE.

**Tuberculosis Hospital Open.**—The new tuberculosis hospital in connection with the Delaware State Hospital, Farnhurst, has been completed and is receiving patients.

**Personal.**—Dr. Peter A. M. Rovitti, Wilmington, has been reelected physician for the Italian Mutual Beneficial Society, and was also elected physician for the St. Anthony Mutual Beneficial Society, succeeding Dr. Henry W. Briggs.

---

[1] Cleveland Medical Journal, November.

**Work of the Laboratory.**—The director of the Pathological and Bacteriological Laboratory of the Delaware State Board of Health, Newark, reports that during July, August and September, 343 analyses and examinations were made.

**Smallpox.**—Two cases have occurred in the St. James Protectory at Reybold, both of which were, it is claimed, imported from Philadelphia. At Woodland 25 out of the population of 100 are said to be affected, and seven deaths have occurred.

## ILLINOIS.

**Wabash Hospital Open.**—The new hospital erected by the Wabash Railway at Decatur has been completed at a cost of $60,000. The hospital is fully equipped and has accommodation for 50 patients.

**Ordered to Refund.**—Dr. Henry C. Neff, an itinerant specialist of Chicago, who contracted to cure a case of catarrh at Kankakee for $56 or refund the money, failed to accomplish the cure, and judgment for the amount was rendered against him by default.

**Abjure Connection with Institution.**—Of the 30 physicians of Freeport, 27 join in a public disclaimer of their connection with the so-called "City Physicians' Laboratory," whose establishment has recently been heralded through the daily press. They furthermore deprecate the methods used as likely to mislead the public, and to attract unbecoming attention to the profession.

**Sanitary Investigation of Cities.**—The State Board of Health has just concluded a sanitary investigation of seventy-five cities of Illinois, the public water supply of which has been subjected to a careful chemical and bacteriologic analysis. In the greater number of cities the water has been pronounced good. In those in which there was evidence of contamination in the water supply, the board has consulted with the local authorities in the endeavor to discover the cause of the pollution and suggest a remedy. Sanitary officers of the board have been sent to the majority of cities for the purpose of investigating unsanitary conditions and to advise the local authorities as to the steps necessary to prevent an outbreak of disease.

### Chicago.

**Thousand for Hospital.**—By the will of the late B. Kuppenheimer $1,000 is devised to the Michael Reese Hospital.

**Children's Department Open.**—The Provident Hospital has opened a department for children, and has established a free clinic for children on Tuesdays and Fridays from 2 to 4 p. m.

**Decrease in Mortality.**—Contrary to the indications of the previous fortnight or so the week's death rate decreased from 15.20 per 1,000 in the week of December 19 to 14.21 in the Christmas week—a decrease of nearly 6.5 per cent. As compared with the corresponding week of last year, when the rate was 17.12 per 1,000, the decrease is almost 17 per cent. This result was wholly unlooked for in view of the character of the weather since Thanksgiving week, and it is still more remarkable when the pneumonia mortality is considered. The total 139 deaths from pneumonia are the highest for any December week on record. They form 27 per cent. of the total mortality from all causes, while the forty-nine deaths from consumption are less than one-tenth the total deaths of the week.

## IOWA.

**Elects Officers.**—The Jasper County Medical Society met at Colfax, December 16, and elected Dr. Louis S. C. Turner, Colfax, president; Dr. F. LeMoyne Smith, Monroe, vice-president, and Dr. Harry P. Engle, Newton, secretary and treasurer.

**Itinerant Sentenced.**—W. C. B. Bullard, an itinerant medicine man of Des Moines, was found guilty of obtaining money from patients under false pretences, and was sentenced to imprisonment for 18 months in the state penitentiary at Anamosa, and to pay all costs.

**Personal.**—Dr. Ferdinand J. Smith, Alton, is to teach pathology in Drake University Medical School, and sails for Germany January 4. He will remain abroad until September.——Dr. Edward S. Bowman, Davenport, has resigned as physician of Scott County.——Dr. James McCartney, Davenport, after living half a century in Davenport, has decided to move to Chicago.——Dr. Charles L. Barewald, Buffalo, has been elected county physician of Scott County.

**Demand Revision of Laws.**—At the recent quarterly meeting of the State Board of Health, a revision of the laws relating to the medical profession was recommended in the following three particulars:

The creation of a special bacteriologic department, which shall have an appropriation of at least $5,000 a year.

Power to act in all cases where it is believed there is danger in an epidemic or disease, even when there has been no outbreak.

Power to accept the certificates of physicians from other states that exact the same preliminary training and subsequent examination as Iowa.

## KENTUCKY.

**Hospital Dedicated.**—The dedicatory exercises of the Jewish Free Hospital, Louisville, were held, December 19, with impressive ceremony.

**Smallpox.**—Richmond and Madison Counties are said to be in the grip of an epidemic. At present there are 14 cases.——The school at Quick's Run has been closed on account of the disease.——Hart County reports an epidemic of a mild form of the disease.

**Personal.**—Dr. Joseph M. Mathews, Louisville, has been awarded $200 damages against the Louisville Railway Company for injuries received some time ago.——Dr. Thomas Morgan, Lexington, has been appointed to the chair of experimental zoology in Columbia University, New York.

**Elections.**—Fayette County Medical Society held its annual election in Lexington, December 15, with the following result: President, Dr. N. Lewis Bosworth; vice-president, Dr. Nathan R. Simmons; treasurer, Dr. James W. Wilson; secretary, Dr. Daniel J. Healy; censor, Dr. Porter Prather, and delegate, Dr. Thomas H. Kinnaird, all of Lexington.——Jefferson County Medical Society, at its regular meeting, December 15, elected the following officers: President, Dr. H. Horace Grant, Louisville; vice-president, Dr. Joseph Hopson, St. Matthews; secretary, Dr. Henry Enos Tuley, Louisville, and treasurer, Dr. Sidney J. Meyers, Louisville.

## MARYLAND.

**Medical Staff Appointed.**—The following have been elected to the executive committee of the medical staff of the Annapolis Emergency Hospital: Dr. George Wells, chairman; Dr. William S. Welch, secretary; Drs. J. J. Murphy and Charles B. Henkel.

**Where Rush Was Taught.**—The annual banquet of alumni of West Nottingham Academy, Cecil County, was held December 18. It was at this academy that Benjamin Rush received his academic training. It was established in 1741 by Samuel Patton, afterward president of Princeton College, and has had 162 years of continuous existence.

### Baltimore.

**Deaths of the Week.**—There were 199 deaths last week, an annual rate of 18.83 per 1,000. Among the chief causes were pneumonia, 29; heart disease, 21; consumption, 19; Bright's disease, 17; cancer and diphtheria each 6, and typhoid fever, 4.

**Pollution of Water Supply.**—There are about 500 cases of pollution on the watersheds of the city's water supply known to the water department. The city solicitor is waging strenuous war on these, especially about 100 due to dwellings. Suit has been instituted already in test cases.

**The Herter Lectures.**—Prof. Paul Ehrlich, director of the Institute for Experimental Therapeutics, established by the German government at Frankfort-on-the-Main, has been selected to deliver the first Herter lectures at the Johns Hopkins Medical School. These lectures are designed to promote a more intimate knowledge of the researches of foreign investigators in medical science. The lectures will be in German and will be given in April. The subject will probably be "Researches on Immunity."

**An Embryo University.**—An arrangement has been effected by which the Baltimore Medical College and the Baltimore Law School are affiliated. After the end of the present session the latter will occupy apartments in the building of the former. It is said that the two institutions contemplate consolidation under a university charter. The medical school was founded in 1880, and is operated in connection with the Maryland General Hospital and a dental school. The law school was founded in 1900. Both have good faculties and large classes.

**Sewerage Bill.**—The sewerage bill approved by the mayor and board of estimates provides for a $10,000,000 loan, to be ratified by the people. The sewer system is to be built by an unpaid commission (except the chairman, who receives $5,000 annually) to be appointed by the mayor, of three republicans and three democrats, with the mayor ex-officio a member. The appointments are to be confirmed by the second branch city council and meetings of the commission are to be public. The commission has power to condemn land, construct the system and require private corporations now using the streets to shift their conduits to make way for the sewers. The work is to be done by contract. House sewage is not to be discharged into the Chesapeake or its tributaries. Buildings are to be connected with the system at the expense of owners and under supervision of the commissioner of health. As soon as the system is ready to relieve 300 buildings, a system of annual sewerage rates is to be established by the mayor and city council.

## MASSACHUSETTS.

**Nurses' Home.**—Medfield Hospital is to have a new nurses' ward two and three stories high, 180 by 140 feet.

**Health Laws.**—The State Board of Health has issued a manual containing all the laws of Massachusetts in regard to health and the decisions made by the Supreme Court relative thereto.

**Diphtheria Epidemic Denied.**—Much has been made in the public press of the prevalence of diphtheria at Harvard. A prompt denial of any danger has been issued by the dean, who suggests the newspaper source of the scare.

**Suggested Appropriations.**—The Massachusetts state auditor suggests the following appropriations to the legislature for the coming year: State Board of Charity, $532,600; Board of Registration in Medicine, $6,850; Cattle Bureau of the Board of Agriculture, in order to avoid releasing tuberculous cows, $100,000, and School for Feeble Minded, $66,248.

**Money to Hospitals.**—The will of the late George W. Boyd leaves $12,500 to Maine General Hospital, Portland, Me.; $5,000 to the Memorial Hospital for Women and Children, Brooklyn, N. Y.; $5,000 to the Children's Hospital, Boston, $1,000 to the Cullis Consumptives Home, Boston, and a reversionary interest of $25,000 to the Massachusetts General Hospital.

**Athletes at Harvard.**—Dr. George L. Meylan, Columbia, in a paper read before the Boston Physical Education Society on "A Study of Harvard University Oarsmen from 1852 to 1892, Inclusive," finds no harm has resulted to the men from the violence of their training or exercise. They average 7½ years longer life than normal, are more apt to marry, and have larger families than the average Harvard men. Moreover, there are more than the average number of "prominent Americans" included in the 152 men thus studied.

## OHIO.

**Medical Corps Reorganized.**—The adjutant general has issued an order for the reorganization of the entire medical department of the militia to conform with the usages and regulations of the United States Army.

**Medical Library for Toledo.**—A medical library has been started in Toledo with cash subscriptions of $200, and a collection of about 2,000 volumes. Rooms have been rented in the residence of the late Dr. George A. Collamore, and Mrs. Collamore is expected to serve as librarian.

**Smallpox.**—The prevalence of the disease at Washingtonville is causing alarm, as there are now 10 cases, and as less than one-half of the school children have been vaccinated.——Gallia County reports several deaths. Two cottages at the Ohio Hospital for Epileptics have been quarantined.——In the west end of Washington County 18 cases have developed during the last few days.

**Under New Management.**—The *Cincinnati Lancet-Clinic*, which has been under the editorial management of Dr. J. C. Culbertson for the past thirty years, will, with the issue of Jan. 2, 1904, present many changes. Dr. Culbertson, while retaining his financial interest in the journal, will retire from active work. Dr. Mark A. Brown will be editor-in-chief and Dr. Frank B. Cross, business manager. Dr. Brown will have associated with him a large corps of associate editors in the various specialities, comprising some of the best-known physicians of Cincinnati. With so capable an editor-in-chief, and so distinguished a staff, the *Lancet-Clinic* should press forward to new scientific and journalistic success.

## PENNSYLVANIA.

**Tuberculosis Hospital.**—The Department of Charities of Pittsburg has asked for an appropriation of $50,000 to build a hospital for the tuberculous.

**Typhoid in Pittsburg.**—There is a large number of cases of typhoid fever in Pittsburg. For the period of the month ended December 14, 283 cases were reported. Ninety per cent. of the patients are said to be of those who drink water from the Allegheny River.

**New Hospitals.**—The Mount Pleasant Memorial Hospital, a four-story structure, with a capacity of 40 beds, has recently been opened.——The new hospital at Uniontown, erected at a cost of $100,000, has been formally opened. This institution will accommodate about 100 patients and has 14 private rooms.

**Not Violence, But Diphtheria.**—A 15-year-old girl, of Philadelphia, died, December 15, at the Pennsylvania Training School for Feeble-Minded Children. An accusation by the father that the child had been violently treated led to an inquest by the coroner of Delaware County. A death certificate of heart disease had been issued. The coroner's jury, however, rendered a verdict of death from diphtheria. The board of managers of the school will investigate the case.

### Philadelphia.

**Bequests.**—By the will of the late Salena Walker, the Jewish Hospital Association and the Jewish Maternity each received a a bequest of $8,000.

**Degrees Conferred.**—On December 10 the University of Pennsylvania conferred the degree of doctor of medicine on eleven students who had finished their course ahead of time.

**Phipps in Philadelphia.**—Henry Phipps, the philanthropist, visited Philadelphia, December 14, and, in company with the director, Dr. Lawrence F. Flick, inspected the temporary quarters of the Phipps Institute of Tuberculosis.

**New Laboratory Soon Ready.**—The new medical laboratory of the University of Pennsylvania, costing about $500,000, is expected to be ready for use next month. The building, begun about two years ago, has been delayed by several strikes of workmen.

**Deaths of the Week.**—The deaths in Philadelphia from all causes within the week numbered 579, an increase of 83 over the last week and an increase of 44 over the corresponding period of last year. The increase is believed to be largely due to the cold weather.

**Will Give Portrait.**—The former resident physicians of the Pennsylvania Hospital are having prepared an oil painting of the late Dr. Thomas G. Morton, which is soon to be hung in that institution. The committee in charge of the portrait consists of Drs. T. Hollingsworth Andrews, James C. Wilson and Frank Woodbury.

**Physician Loses Feet.**—Dr. George I. MacLeod of Ardmore, on December 16, in attempting to board a train for Philadelphia, slipped and fell beneath the moving train, and had both legs crushed. Amputation of both feet was necessitated. The patient is in good condition. Dr. McLeod is a member of the staff of the Bryn Mawr Hospital.

**Wyman Lectures.**—On the invitation of the H. A. Hare (Undergraduate) Medical Society, Surgeon-General Walter Wyman, of the U. S. P. H. and M.-H. Service, on December 16, addressed the students of the Jefferson Medical College on "Advantages Offered by the Public Health and Marine-Hospital Service of the United States to Recent Graduates in Medicine."

**More Medical Inspectors.**—Councils' subcommittee on finance has recommended an increased number of medical inspectors. According to the plan there are to be 50 salaried inspectors, assisted by 20 nurses, who are to do the work now done by 90 district physicians, medical inspectors and vaccine physicians. The new plan will simplify the work and will enable a daily inspection of schools to be carried out. The salaries of the inspectors are to be $1,200 a year, and that of the nurses $720 a year.

**Smallpox.**—For the week ended December 19 there were 90 new cases of smallpox and 22 deaths, the latter being more than for any like period within two years. Dr. Martin, director of the Department of Health and Charities, has sent the following letter to the physicians of the city, dated December 19:

> The conditions in Philadelphia are such as to threaten a grave epidemic of smallpox. Can you help in the preventive work by urging on your patients and all members of their households immediate vaccination of all unvaccinated persons, of all children over 12 who have been vaccinated successfully in infancy, of all adults who have not been vaccinated successfully within the last five years.

## GENERAL.

**Echinacea.**—According to L. E. Sayer, dean of the School of Pharmacy of the University of Kansas, writing in *The Journal of the Kansas Medical Society*, there is such a large and increasing demand for *Echinacea angustifolia* (the common "black Susan" or "niggerhead" of the western roadside and field corner) that there is danger of the supply for medicinal use being exhausted. The Bureau of Plant Industry of the

Department of Agriculture will take steps next season for the cultivation of the plant.

**American Congress on Tuberculosis.**—The Council of the Indiana State Medical Association, at its meeting in Indianapolis, December 17, adopted the following resolutions:

*Resolved*, That the Council of the Indiana State Medical Association, representing the medical profession of Indiana, believing that the so-called American Congress on Tuberculosis, organized by Clark Bell, Esq., of New York is not a body which is representative of the medical profession or of the best scientific thought of this country, deems it inadvisable and inexpedient for the Indiana State Medical Association to be represented in said Congress, and that we advise our President to notify Mr. Bell that he declines to appoint delegates to it.

*Resolved*, That the Secretary of the Council be instructed to furnish a copy of this resolution to the medical press, to Hon. John Hay, Secretary of State at Washington, who has been specially importuned to lend official aid and support to the movement.

**Physicians Wanted for Philippine Service.**—The United States Civil Service Commission announces that on Jan. 27-28, 1904, an examination will be held at 183 cities throughout the United States to secure physicians for the Philippine Service at salaries ranging from $1,200 to $1,800 per annum. At least one year's experience in hospital work or in the Philippine Islands as assistant surgeon in the United States Army, is prerequisite. The age limit is 20 to 40 years. This examination is open to all citizens of the United States who comply with the requirements. The Philippine Service is classified, and the law contemplates promotions on the basis of merit from the lowest to the highest positions. The climate is good and nearly all of the employes are in excellent health. For circulars, giving cost of living, duties, places of examination, etc., address the commission at Washington, D. C.

**St. Louis Exposition—The Congress of Arts and Science.**—A congress of scientific men to be called The Congress of Arts and Science is to be held in St. Louis, Sept. 19 to 25, 1904. This congress is supposed to cover all the sciences, classified into twenty-five departments, each department including several divisions. It was decided to invite a foreign representative of each subdivision to be present and take part. During the summer a committee was in Europe to personally extend the invitations. As a result we understand that about one hundred and twenty distinguished foreigners have accepted. Among these are M. Henri Becquerel, Paris (Physics of the Electron), J. H. van't Hoff, Berlin (Physical Chemistry), Albrecht Kossel, Heidelberg (Physiological Chemistry), Wilhelm Waldeyer, Berlin (Human Anatomy), Theodor W. Engelmann, Berlin (Physiology), Wilhelm Erb, Heidelberg (Neurology), Felix Marchand, Leipzig (Pathology), G. Clifford Allbutt, Cambridge (Internal Medicine), Professor Richelot, Paris (Gynecology), Sir Felix Semon, London (Otology and Laryngology), Sir Lauder Brunton, London (Therapeutics), Major F. W. Ross, Liverpool (Tropical Medicine) and Theodor Escherisch, Vienna (Pediatrics). Each of these, we understand, will be given an honorarium. As the program shows, Monday and Tuesday will be devoted to sessions of the larger divisions, and then the congress will break up into sections. These will be so arranged that, although some fifteen will be in session at once, or thirty in the morning and afternoon of each day, the sections of a department or of related departments will be arranged in series during the last four days in such manner that nearly everybody will be able to attend the sections up to the number of twelve in which any given individual might be supposed to be interested.

**Health Officers' School.**—A school for Indiana's health officers was held in Indianapolis, December 16-17, under the auspices of the State Board of Health. Under the Health Law of Indiana the State Board of Health is supreme and has power at any time to summon health officers in conference on hygiene and all subjects pertaining to the public health. The expenses of the officers are paid by their respective boards, but no per diem is allowed, as the officers are paid so much per capita per annum for each inhabitant of his jurisdiction. The school was called to order at 9 a. m. December 16 by Dr. W. N. Wishard, president of the State Board of Health. The first paper was given by County Health Officer A. S. Tilford on "The Importance and Usefulness of Vital Statistics." This valuable paper drew forth many questions and considerable discussion. There followed a lesson by Dr. J. N. Hurty, secretary of the board, entitled "Instructions for Collection of Vital Statistics; Instructions in Quarantine, and in the General Duties of Town Health Officers." A special "Book of Instructions to County, City and Town Health Officers" was recently issued by the State Board of Health, and this book was for the first time distributed among those present, about 200 in number. Health boards in Indiana have extraordinary powers, for the Supreme Court has decided that "boards of health are empowered to do whatever is reasonable for the preservation of the public health and the suppression of epidemics." All health officers are empowered and commanded on their own judgment to establish quarantine, employ physicians, purchase supplies, destroy infected articles, establish pesthouses, etc. The State Board of Health is empowered to take charge of any city, town, county or locality wherein the health laws are not being enforced. All of these facts in regard to the duties and powers of health officers, were carefully set forth and explained by the lecturer.

Two lessons in hygiene were given by Prof. Severance Burrage, professor of hygiene in Purdue University. His first subject was "School Sanitation and the Necessity of Medical Inspection of School Children," and his second, "The Town Milk and General Food Supply." Ex-Attorney-General William L. Taylor gave a lucid and comprehensive exposition of the present health and medical laws of Indiana, and made suggestions as to the legislation on those subjects that are still needed. Mr. Taylor was selected for this work because of his peculiar fitness, he having written the greater part of the health and medical laws of the state, while attorney-general, and having done good work in securing their passage. Surgeon-General Sternberg was one of the teachers, and his first lesson was given under the title of "Prevention of Infectious Diseases." In giving this lesson General Sternberg went carefully into the technical details, with which the health officer should be thoroughly acquainted. Dr. Frank Allport of Chicago gave a lesson entitled "Examination of School Children's Eyes and Ears." Dr. Allport dwelt fully on the importance of the subject and gave a clinic, examining the eyes of children before the assembled audience, to illustrate what a simple matter it was for teachers to be able to discover whether or not sight and hearing in their pupils were normal. Dr. Allport's address is spoken of as one of the most important given during the school, being exceedingly practical, and it certainly will bear fruit in Indiana, as the state board has already decided to order the examination of school children's eyes and ears by the teachers, and to use the methods advocated by Dr. Allport.

Dr. C. O. Probst, secretary of the Ohio State Board of Health, gave a lecture entitled, "The Combat Against Tuberculosis." This lesson was confined largely to telling in detail the part which health officers should take in the great work of the prophylaxis of tuberculosis. Prof. Stanley Coulter, professor of botany, Purdue University, gave a lesson entitled, "Influence of Plant Life on the Public Health." This was a very brilliant address by one of the foremost botanists of the United States. He made plain how the earth would speedily become uninhabitable if plant life was not present to unceasingly purify the atmosphere, to conserve humidity, furnish food, etc. Professor Coulter will prepare a pamphlet on this subject which will be circulated by the Indiana State Board of Health.

Surgeon-General Wyman, who had promised to be present, could not attend, being kept away by the pressing duties of his office. Probably the most notable lesson was given by Prof. F. G. Novy, M.D., of the University of Michigan. His title was "The Protozoal Diseases." It would seem impossible for any one except Professor Novy to give even an abstract of the matter which he presented to the school. The authorities of the Medical College of Indiana prevailed on Dr. Novy to remain over and address the students of their institution the next day.

To the evening session of the school, on December 16, the public was invited. The auditorium, seating 1,200, was full to the doors. The lectures of the evening were given by Dr. David W. Dennis, professor of biology in Earlham College, and by Surgeon-General Sternberg. Both lectures were illustrated with lantern. The first was entitled "The Germ Theory of Disease," and the second "Infection and Immunity."

The medical profession and other citizens of Indianapolis and of the state extended to General Sternberg, Dr. Novy, Dr. Allport and Dr. Probst a dinner on the evening of December 17, at which Governor Durbin acted as toastmaster and Mayor Holtzman extended welcome to the visitors.

## FOREIGN.

**The Deadly Celluloid Collar.**—The *Progrès Médical* of Paris states that a French practitioner, Dr. Runel, succumbed in twenty-four hours to the effects of burns received from the igniting of a celluloid collar while he was lighting a cigar.

**Medal for Ehrlich.**—Professor Ehrlich, the director of the Institute for Experimental Therapeutics at Frankfurt a. M., has been presented with the gold medal "for arts and sciences." A similar medal was bestowed on Virchow on his eightieth birthday.

**French Medicine at the St. Louis Exposition.**—Dr. Marcel Baudouin, editor of the *Gazette Méd. de Paris*, has been appointed chairman of the committee that will represent French medicine at the approaching exposition. He is making great efforts to have the profession in his country well represented, not only by surgical appliances, etc., but also by a large contingent of visiting French physicians.

**Russian Tuberculosis Congress.**—The national medical association of Russia appointed a permanent committee last year to study means of combating the spread of tuberculosis. The committee has now appealed for a general conference on the subject, and has been entrusted with the task of organizing an All-Russian Tuberculosis Congress to convene in connection with the next national medical congress.

**Substitution of Infants.**—A Polish noble family has recently been before the courts on account of the accused substitution by the wife of an infant heir. The matter was referred by the court to the expert testimony of two physicians and an artist, who were required to testify as to the inheritance by the infant of the physical characteristics of the mother to sustain her claims of maternity. The experts discovered likeness in the ears, root of the nose and color of the eyes, and noted a striking resemblance between the infant's chin and the chins of the countess' daughters, although differing from her own chin. On the ground of this testimony the mother's claim was allowed and the suit dismissed. The trio of Berlin experts included Dr. Strassmann and Vogel, the portrait painter.

**Celebration of Koch's Sixtieth Birthday.**—Robert Koch is not expected home from British South Africa until March, but his friends seized the occasion of his sixtieth birthday, December 11, to honor him. A portrait bust installed in the Institute for Infectious Diseases, will be unveiled on his return, and a museum has been organized there to represent the evolution of bacteriology. A *Festschrift* with contributions from his immediate pupils is now in press, and all the German medical journals devoted a special number to his honor. The *Deutsche medicinische Wochenschrift* states that the preparations for the celebration have been made without publicity as the sixtieth birthday of even such a man as Koch scarcely justifies a public celebration, but adds the mysterious hint that "it may be allowable later to speak of the primary inducement for this more extensive celebration of the birthday." This weekly has always been the medium through which Koch has published his communications, and it gives a list of 22 since his criticism of Naegeli's work in 1877.

### PARIS LETTER.

#### Protection of Children from Tuberculosis.

The establishment of sanatoria for consumptives in France has not taken place without some discussion as to whether it be the best means of stamping out tuberculosis. Professor Grancher considers that prevention is of more importance, and advocates using all methods which tend to protect children from this disease. He considers the English method far preferable, the latter consisting in ameliorating the hygienic conditions of workmen in furnishing more light and air, and better food. A society has been formed under his inspiration, which aims to protect children from tuberculosis. Children of the poor whose parents are affected with consumption will be sent into the country, after having been examined to see if there is any apparent trace of consumption. It is considered best not to send tuberculous children among families residing in the country who would not know how to protect themselves. The family of the child will be asked to contribute in some slight degree to the maintenance of the child. The sum given for this purpose may be only two or five francs per month, but it will prevent pauperizing the family. Children whose ages range from 5 to 13 will be chosen.

## Correspondence.

### Trades Unionism Among Asylum Employes.

Dunning, Ill., Dec. 23, 1903.

*To the Editor:*—I presume it is well known, from the notices that have appeared in the daily press of Chicago, that there is established at Dunning a union of attendants and nurses, organized on the same basis as regular labor organizations and affiliated with the Chicago Federation of Labor. It is also a well-known fact that the attendants and nurses, as well as other employes at Dunning, are under the protection of civil service, the protection being so strong as to absolutely prevent me from either hiring or discharging an employe.

The attendants have made a demand for a uniform scale of wages, much higher than the present one, and in spite of the fact that the average pay allowed to attendants and nurses at Dunning is now somewhat higher than the average in the state institutions in Illinois, and in fact higher than the average for the United States. I am not opposed to an increase in the wages, and quite agree with Mr. Sullivan, the attorney for the union, that for a better salary we would be able to secure a better grade of attendants. I do, however, very decidedly disagree with the demands of the union on the question of the uniformity of wages, and this is the question which I desire to place before the medical profession through the medium of The Journal. The points which I desire to establish and which in my opinion are absolutely essential for the maintenance of discipline in an institution of this kind, as well as for the obtaining of the highest possible efficiency from the attendants and nurses, are the following:

1. While I have absolutely no objection to an association of attendants and nurses and can easily see how such an association could be of immense service to its members as well as to the institution, particularly to the patients, I can not see the wisdom of having a regular labor union in a charitable institution. I maintain that if it is undesirable to have a union of firemen and policemen, it certainly is less desirable to have a union of attendants and nurses and there is much less just reason for its existence, especially when we consider that it exists in civil service protection.

2. I assert that the work is in no way uniform. The skillful nursing of the sick and the care of the demented, helpless and untidy patients surely deserves higher compensation than the watching of a few working patients out in the field, where about the only duty is to prevent the patients from escaping or overworking.

3. What is most important, the uniform scale of wages would undoubtedly decrease the efficiency of the great majority of attendants. Such is the opinion of over fifty superintendents of leading American institutions of a similar nature, and such has already been my experience. It is proper to consider an expectation of higher pay and higher position a natural stimulus for work. If the question of pay is absolutely settled and there is no chance for any better, and on the other hand no danger of any worse, why should anyone care to improve in his work and to receive any training? The only thing desired under such circumstances is work enough to prevent discharge. You will agree with me that under such circumstances the work in an institution of this kind certainly can not be elevated nor the care of patients be bettered.

4. The discipline of the place under such circumstances can be easily imagined. As it is, the civil service rules limit the power of the superintendent. If, aside from that, he has no right to make some distinction in salary for better services rendered, the superintendent will become a mere figurehead.

To illustrate the situation in state institutions of Illinois, I will cite the system existing at the Illinois Eastern Hospital for the Insane, which was put in operation by Dr. Dewey and which has been continued practically the same ever since. The male attendants are placed in eight different grades, from $25 up to $40 per month. The average pay for male attendants, including several who have received training equal to that of a trained nurse, is $28,87. At Dunning, where none of the older employes had any training whatever, the average is now $30.60 per month. The female attendants at Kankakee are placed in eleven different grades, starting at $17 per month up to $35 per month, and practically every position paid better than $22 per month is held by a nurse who has received training and diploma from a training school. That makes an average of $20.19 per month for each female attendant. The average at Dunning is $28.80 per month. My schedule, as presented in the estimate, provides for an average for attendants of both sexes amounting to about $32.

In closing I wish to add that the training school has already been organized at Dunning and a course of training started, and while the interest taken in the classes and the result of the quizzes is extremely poor, the training will surely be of considerable benefit to the institution as well as to each attendant who takes interest in it. It is my object to give a sufficiently thorough course of training in the second year to be able to train our own nurses for the positions of head nurses and all superior positions.

I am certain, however, that with uniform scale of wages no such results can be expected and the institution will drift along way behind the times, simply because of lack of efficiency in the force of attendants and nurses.

V. H. PODSTATA, M.D.,
*General Superintendent Cook County Institutions.*

### "Congresses on Tuberculosis."

NEW YORK CITY, Dec. 14, 1903.

*To the Editor:*— . . . The American Congress on Tuberculosis was founded by the Medicolegal Society in 1900, and has held its annual meetings and elected its officers each year since that time at the City of New York. This congress is not, nor was it ever, for a moment, considered as a strictly medical organization. It was composed of legal and medical men, scientists, and publicists, because the medical profession, as such, in this country failed to organize such a congress, although all the leading powers of christendom had moved and acted. Sweden, Italy, Germany, France and England had done so.

The Medicolegal Society, because of the inaction of the medical profession of America, considered that if consumption was a communicable disease, as their medical members believed and advised, that the highest questions in forensic medicine ever submitted to the two great professions of law and medicine were:

(1) "What legislation could be adopted by Congress or by the legislatures of the American states that could possibly arrest its ravages, prevent its spread, and reduce the mortality among our people that had reached such alarming and amazing proportions?" as the first question, and,

(2) "How could the masses of our people be educated up to be willing to vote for and aid in securing such legislation as a commencement; and to form and place on solid foundations a public opinion in America, among all classes of our people, that could be relied on to enforce such laws, after they were enacted?"

The Medicolegal Society then considered that, because of the exigencies of the questions, the supineness and inactivity of the medical profession in our country to grapple with the subject, it became an urgent, an immediate and the paramount duty of lawyers, jurists, medical men, scientists, legislators and the general public in such a struggle to inquire into all sides and phases of this question. . . .

If the medical profession had in 1900 organized a national movement or congress on tuberculosis, as that profession had done in almost all continental countries, it would have been a creditable work, and . . . it is only fair to say that the present congress would not have been organized.

If the medical professsion should to-day, through its great national organizations, decide to call and hold a medical congress on tuberculosis, either on broad or restricted lines of labor, as to the medical questions involved, or on larger and broader lines, it would be a creditable work, and every member of this organization would aid it in every way. . . .

As this Congress is not a medical congress, *per se*, and as men of all professions are on its list of officers and members, its faults ought not to, nor could they ever, be laid at the door of the medical profession.

(Signed) CLARK BELL,
*Chairman Committee on Organization,*
*International Congress on Tuberculosis.*

[Because of lack of space for them, we have omitted from Mr. Bell's very long letter a number of paragraphs, some of which are a repetition of a considerable part of the letter from the Government (which has already appeared in THE JOURNAL, December 12). We print the above portions, which are pertinent to the matter discussed. Mr. Bell discusses the Lewis-Brown Congress, which discussion we omit, as we do not wish to enter into the controversy between the two congresses. We note that Mr. Bell relieves the medical profession from responsibility of any sort for the congress, and it is well for physicians to know this fact.—ED.]

### The First Hip-Joint Amputation in America.

WINFIELD, ARK., Dec. 18, 1903.

*To the Editor:*—In THE JOURNAL, December 5, page 1379, in his address on "The Progress of American Medicine," etc., Dr. W. W. Grant of Denver, speaking of great surgical operations of the past, gives the late Dr. V. Matt the credit of the first "hip-joint amputation" in America, in 1824. This is not correct, as we find, on pages 4 and 5 of Dr. P. S. Townsend's preface to volume III of Velpeau's Operative Surgery, 1847, that he gives Dr. Walter Brasher of Bardstown, Ky., the credit of the first hip-joint amputation, which was performed in August, 1806. In 1891, this question was discussed by Dr. Will F. Arnold of the U. S. N. and myself, and our communications were published in the *Medical Record.* In one number of that journal I had a copy of Dr. Brasher's letter to Dr. Townsend published.

Dr. Wyeth of New York, in the third edition of his "Text-Book of Surgery," page 218, gives Dr. Brasher credit for the first operation of the kind in America, and cites Dr. Yandell of Kentucky as authority. Dr. Eve, in his "Surgical Cases," gives the proper author of the operation, as Townsend did.

I write this simply to place the credit on the right man, and on the right date. CHEVES BEVILL.

## Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### DIFFERENTIAL DIAGNOSIS OF TYPHOID FROM MEASLES AND RHEUMATISM.

RIDGELAND, WIS., Dec. 25, 1903.

*To the Editor:*—CASE 1.—A patient, 4½ years old, came down with a high fever and aches and pains all over her body. She had been exposed to measles. By the end of the first week her temperature was 104. At this time also there was pain in her abdomen and it was also tympanitic and covered with roseola. Her bowel movements were like pea soup and there was some blood. Spleen was enlarged. She gradually grew better until the end of the second week, when her temperature was 100. During the second week there was also bronchitis. Beginning with the third week there was a rise of temperature and the second day she broke out with measles. She then rapidly recovered. I diagnosed the case typhoid fever. Was I right or was it measles? She had two good sweats at the first.

CASE 2.—A woman, 38 years old, after three days of being unwell and having a very sore throat, came down with pain and swelling in her joints, mostly in wrists and elbows, ankles and knees; there was much vomiting and there was enlargement of spleen; temperature was from 100 to 101; there also was a marked roseola on abdomen. Tongue covered with white coating, breath bad. She was constipated, but there was no sweating. I diagnosed the case rheumatic fever. I opened the bowels with colchicin, and just at this time another physician was called, who pronounced it typhoid fever. Under typhoid treatment her temperature would run up to 101, while under rheumatism treatment her temperature would remain at 99.6. She finally recovered with stiffness in the joints. Who was right?

C. C.

ANSWER.—CASE 1.—There are two or three possibilities in this case. (A) The patient had typhoid which was followed by measles. The early fever, abdominal symptoms, roseolæ, stools, splenic tumor, hemorrhage from the bowels, etc., speak as strongly for typhoid as any symptoms could, in the absence of a Widal test. (B) In some cases, in young children at this age, the typhoid spots, usually small, few and confined to the trunk, may come out very diffusely, abundantly and with unusual distribution, as over the face, arms, hands, etc. These cases may resemble measles, and careful observers have recorded such cases, although relatively infrequent. We have seen typhoid in which the diagnosis of measles was made. The Widal test, finding the typhoid bacilli in the blood and urine, etc., removed all doubt of the diagnosis. Your case was, then, in all probability typhoid with, as an equal choice, measles as a sequel or an unusually abundant typhoid eruption.

(c) It is barely possible that the prodromal fever of two weeks was part of the measles incubation. This seems, however, by far the least probable explanation.

Case 2.—Your second case seems to have been rheumatic. There was an initial sore throat, then joint involvement, vomiting (unusual in typhoid), splenic tumor, which is not infrequent in acute rheumatism, a lower fever than usually occurs in typhoid, and, above all, the success of the almost specific antirheumatic treatment.

### PARATYPHOID SYMPTOMS AND PATHOLOGY.

Nashville, Tenn., Dec. 14, 1903.

*To the Editor:*—Please state in The Journal the postmortem findings of the disease produced by the paratyphoid bacillus, also the symptoms and in what respect they differ from typhoid.

W. L.

Answer.—The symptoms of paratyphoid fever are practically indistinguishable from those of typhoid. Usually the course is similar to that of a rather mild typhoid, and the mortality seems to be low. Bowel disturbance is usually less marked, but may be present, and hemorrhages occasionally occur. Rose spots, enlarged spleen and dicrotic pulse are present to about the same extent as in typhoid. The diagnosis is to be made by the failure of the Widal in dilutions above 1-20, which is suggestive, and the isolation of the paratyphoid bacillus from the blood, which is the only positive method. In the few recorded autopsies the disease differs from typhoid in absence of swelling of the Peyer's patches and lymphatic apparatus of the intestine, although in a few superficial intestinal ulcerations have been found. The anatomic picture is rather that of a non-specific septicemia.

### FIRST USE OF CLINICAL THERMOMETER.

Jet, Okla., Dec. 26, 1903.

*To the Editor:*—Will you please inform me through your columns when and by whom the thermometer was first used for the purpose *of determining the temperature of the body?* L. J. Moorman.

Answer.—The medical use of the thermometer apparently dates back almost to its invention. Park refers to Santoro or Sanctorius (1561-1635), professor at Padua, who taught how to study the temperature by means of a species of thermometer, probably of his own invention. As Galileo (1574-1642) is credited with the invention of the spirit thermometer, it will be seen that the medical idea of an instrument of precision for determining the temperature dates back fully to his time. Mercuric thermometers were not invented until a later date. The clinical thermometer as we now use it is, of course, a modern invention.

### PHARMACOLOGY TEXT-BOOKS.

Lamont, Fla., Dec. 21, 1903.

*To the Editor:*—Will you kindly inform me through The Journal which is the best book printed in either English, French or German on the subject of Pharmacology, and where I can obtain it?

A. E. Conter.

Answer.—There is no better English work than Sollmann's. Cushny's is also good. Order from W. T. Keener & Co., Chicago, or L. S. Mathews & Co., St. Louis, or have your nearest book dealer do so.

### THE SUBMERGED TONSIL.

Fort Yellowstone, Wyo., Dec. 14, 1903.

*To the Editor:*—Will you please inform me what is meant by the phrase "Submerged Tonsils"? One of my patients was under the care of an eminent nose and throat specialist, who said she had submerged tonsils.

J. V. White,
Contract Surgeon, U. S. A.

Answer.—The term "submerged tonsil" has been used by some laryngologists to describe the gland when it is small, flat and elongated and partially covered by the faucial pillars to which it is sometimes adherent. The adjective has not received recognition.

## Marriages.

L. Edwin Young, M.D., Massack, Ky., to Miss Mary Gholson, December 25.

John R. Wilson, M.D., to Miss May Scott, both of Prairie Creek, Ind., December 8.

Grant G. Brown, M.D., to Miss Lutie Bowen, both of Atchison, Kan., December 23.

Lorin F. Rich, M.D., Rexburg, Idaho, to Miss Ruth Blair of Salt Lake City, December 23.

J. E. Wilson, M.D., Terrell, Texas, to Miss Johnnie Mae Blain of Dallas, Texas, December 9.

Robert T. Legge, M.D., to Miss Irene Farjeon, both of St. Cloud, Cal., at San Francisco, November 26.

Herbert H. McCampbell, M.D., Knoxville, Tenn., to Miss Edna White of Springfield, Tenn., December 25.

Edward Livingston Trudeau, Jr., M.D., Saranac Lake, N. Y., to Miss Hazel Martyn of Chicago, December 28.

George A. Carr, M.D., Durham, N. C., to Miss Bettie May Hunt of Oxford, N. C., at Durham, December 14.

Edward J. Ruddock, M.D., Guerneville, Cal., to Miss Eva L. Stanford of Alameda, Cal., at Santa Rosa, Cal., December 16.

Emmett P. North, M.D., St. Louis, Mo., to Miss Maud Isbell, daughter of Dr. John Isbell of Washington, Mo., December 2.

James Robb Church, M.D., U. S. Army, Fort Trumbull, Conn., to Miss Beulah Maude Boss of New London, Conn., December 9.

Arthur Marston Stimson, M.D., assistant surgeon U. S. P. H. and M.-H. Service, to Miss Sarah A. Boyd of Tiverton, R. I., at New Orleans, December 9.

## Deaths.

**Harry C. Hume, M.D.** Kentucky School of Medicine, Louisville, 1892, of Paragould, Ark., a member of the American Medical Association, Arkansas Medical Society, and Greene County Medical Society, died at his old home, New Harmony, Ind., Dec. 17, after an illness of more than two years from consumption, aged 30.

**William Scarborough Braxton Henry, M.D.** Jefferson Medical College, Philadelphia, surgeon of the Fortieth Virginia Infantry, C. S. A., in the Civil War, some-time physician to the Omaha and Winnebago agencies in Nebraska, died in Falls Church, Va., December 12, from heart disease, after a brief illness, aged 76.

**Corydon Pirnie Cronk, M.D.** Columbian University, Washington, D. C., 1888, of Norfolk, Va., for ten years in charge of the Baltimore station of the U. S. Weather Bureau and for the last six years stationed at Cape Henry, Va., died at the City Hospital, Baltimore, December 13, from Addison's disease, aged about 45.

**Francis W. Higgins, M.D.** New York University, 1881, a member of the American Medical Association, vice-president of the New York State Medical Association, and president of the Third District branch of that organization, died suddenly in his office at Cortland, N. Y., from heart disease, December 18, aged 46.

**Francis A. Kitchen, M.D.** University of Pennsylvania, Philadelphia, 1856, formerly surgeon of volunteers in the Civil War; medical director of the Department of Ohio, G. A. R., and city physician of Toledo, died at his home in that city, December 18, from pneumonia, after an illness of four weeks, aged 83.

**Samuel B. Howell, M.D.,** of Philadelphia, some-time secretary of the Philadelphia College of Physicians, one of the founders of the Medico-Chirurgical College, and dean of the Auxiliary Department of Medicine of the University of Pennsylvania, died at Atlantic City, N. J., December 12.

**William H. A. Young, M.D.** Eclectic Medical College of the City of New York, 1872, was shot through the heart and killed by the accidental discharge of a rifle which he was placing in his carriage, at his home in Springfield, Mass., December 26.

**John W. Hamilton, M.D.** Bennett College of Eclectic Medicine and Surgery, Chicago, 1870, who had suffered for several months from insomnia, committed suicide by taking cyanid of potassium, at his rooms in San Francisco, December 14, aged 66.

**George E. Blackman, M.D.** State University of Iowa, College of Homeopathic Medicine, Iowa City, 1886, of Vernon, Texas, died recently from consumption, in the mountains of Colorado, where he had gone for his health.

**J. Reynolds Tillinghast, Jr., M.D.** College of Physicians and Surgeons, New York, 1895, of Saranac Lake, N. Y., died at Colorado Springs, Colo., December 13, from consumption, after a long illness.

**Charles L. Tindall, M.D.** Hahnemann Medical College, Philadelphia, 1888, died at his home in Philadelphia, December 15, from tuberculous laryngitis, after an illness of several months.

**Charles A. Moran, M.D.** Southern Medical College, Atlanta, Ga., 1885, of Atlanta, died at St. Joseph's Infirmary in that city, December 20, from anemia, after a long illness, aged 45.

**Charles H. Bushong, M.D.** College of Physicians and Surgeons, 1885, died December 20, from consumption, after an illness of two years, at his home in New York City, aged 47.

**William R. Harper, M.D.** American Medical College, St. Louis, 1889, died at his home in Mitchellville, Ill., December 7, from heart disease.

**Robert Garrett Dock, M.D.** Hahnemann Medical College, Philadelphia, 1894, died at his home in Germantown, Philadelphia, December 15.

**Brooks R. Hamilton, M.D.** College of Physicians and Surgeons, Keokuk, 1870, died at his home in Nauvoo, Ill., December 9, aged 66.

**Samuel Thomas, M.D.**, died at his home in Greenville, Ohio, December 17, from dysentery, after an illness of two weeks, aged 76.

**William M. Skeler, M.D.** University of Michigan, Ann Arbor, 1870, dropped dead at his home in Three Rivers, Mich., December 15.

**William S. Hopson, M.D.**, the oldest practitioner of Hopkinsville, Ky., died at his home in that place, December 18, aged 89.

**Jerome A. Anderson, M.D.** University of California, San Francisco, 1873, died at his home in San Francisco, December 26.

**Oscar F. Decker, M.D.** University of Buffalo, 1871, died at his home in Buffalo, N. Y., from apoplexy, December 11, aged 64.

**James R. D. Long, M.D.** University of Nashville, 1880, died suddenly at his home in Richardson, Texas, December 15.

**Samuel Sanford, M.D.**, 1849, died at his home in Lima, Ohio, December 17, after a long illness, aged 75.

**J. H. Pickett, M.D.**, died at his home in Ty Ty, Ga., December 15, from dropsy, after a long illness.

**Mathias Brand, Jr., M.D.** Chicago Medical College, 1886, died at his home in Chicago, November 21.

**J. L. Scott, M.D.**, died at his home in Denison, Texas, December 17, aged 84.

## Miscellany.

**Apropos of the Anti-Bath Doctor.**—The following ode, which appeared in the Chicago *Record-Herald* Dec. 22, 1903, was suggested by an eclectic physician's having preached against the custom of bathing.[1] Although this will not go down to future ages as an example of the finest poetry, it nevertheless contains enough point to be worthy of reproduction.

OWED TO DR. R——.

Who is the man who takes no bath?
Who claims to health it is the path?
Who in his system no germs hath?
A doctor!!!

Who says that soap destroys all fat?
Who's never in a "sitz bath" sat?
Who simply will not bathe—that's flat?
A doctor!!!

Who "sets aside claims excretory"?
Likewise all claims respiratory?
Who leaves it to perspiratory?
A doctor!!!

Who seems to emulate the tramp?
Who never gets his system damp?
Who if he bathes might have a cramp?
A doctor!!!

—M. G. SMITH.

## State Boards of Registration.

### COMING EXAMINATIONS.

Utah State Board of Medical Examiners, Salt Lake City, Jan. 4, 1904. Secretary, Dr. R. W. Fisher, Salt Lake City.

State Medical Examining Board of Washington, Tacoma, Jan. 5-6, 1904. Secretary, Dr. P. B. Swearingen, Tacoma.

Board of Medical Examiners of Arizona, Phoenix, Jan. 4-5, 1904. Secretary, Dr. Wm. Duffield, Phoenix.

State Medical Examining Board of North Dakota, Grand Forks, Jan. 5, 1904. Secretary, Dr. H. M. Wheeler, Grand Forks.

Board of Medical Examiners of the State of Oregon, Portland, Jan. 5, 1904. Secretary, Dr. Byron E. Miller, Portland.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Jan. 5 6, 1904. Secretary, Dr. S. D. Van Meter, Denver.

Minnesota State Board of Medical Examiners, State Capitol Bldg., St. Paul, Jan. 5-7, 1904. Secretary, Dr. C. J. Ringnell, Minneapolis.

State Board of Health of Rhode Island, State House, Providence, Jan. 7, 1904. Secretary, Dr. G. T. Swarts, Providence.

Indiana State Board of Medical Registration and Examination, Indianapolis, Jan. 13, 1904. Secretary, Dr. W. T. Gott, Crawfordsville.

Board of Medical Examiners of South Dakota, Cataract Hotel, Sioux Falls, Jan. 13-15, 1904. Secretary, Dr. H. E. McNutt, Aberdeen.

Wisconsin Board of Medical Examiners, Milwaukee, Jan. 12, 1904. Secretary, Dr. F. R. Forsbeck, Milwaukee.

State Medical Board of Arkansas, Little Rock, Jan. 12, 1904. Secretary, J. P. Runyan, Little Rock.

Vermont State Board of Medical Censors, Y. M. C. A. Bldg., Burlington, Jan. 13-14, 1904. Secretary, Dr. S. W. Hammond, Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, Jan. 14, 1904. Secretary, Dr. Wm. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, Jan. 14-16, 1904. Secretary, Dr. J. A. Egan, Springfield.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

New York State Board of Regents, at New York, Albany, Syracuse and Buffalo, Jan. 26-29. Secretary, James Russell Parsons, State Capitol, Albany.

**Oklahoma Report.**—Dr. E. E. Cowdrick, secretary of the Oklahoma Medical Examining Board, reports the written examination held at Enid, November 10, as follows: Subjects, 9; questions, 77; percentage, 66 2/3; applicants, 18; passed, 5; failed, 13.

| Colleges. | Year Grad. | Per Cent. |
|---|---|---|
| Amer. Med. Missionary Coll., Chicago | 1902 | 86.5 |
| Cleveland Hom. Med. College | 1901 | 83.0 |
| Missouri Medical College | 1884 | 81.3 |
| University of Missouri | 1899 | 80.5 |
| Hospital Coll. of Med., Louisville | 1903 | 81.6 |

FAILED.

Those who failed were graduates of: Toledo (Ohio) Medical College, 1886; Central Coll. of P. and S., Indianapolis, 1903; Rush Med. Coll., Chicago, 1878; Miami (Ohio) Med. College, 1902; Coll. of P. and S., Baltimore, 1876; Univ. of Kentucky, 1903; Kansas City Med. Coll., 1903; Univ. of Louisville, 1897; Memphis Hosp. Med. Coll., 1892; Hosp. Coll. of Med., Louisville, 1898; Coll. of P. and S., Keokuk, Iowa, 1876; Barnes Med. Coll., St. Louis, 1897.

## The Public Service.

### Army Changes.

Memorandum of changes of stations and duties of medical officers for the two weeks ending Dec. 26, 1903:

Webb, W. D., Turnbull, Wilfrid, and Porter, Ralph S., asst.-surgeons, ordered to proceed to Washington, D. C., and report to the president of the examination board for examination to determine their fitness for advancement.

Peed, George P., and Thomason, H. D., asst.-surgeons, ordered to proceed to San Francisco and report to the president of the examining board for examination to determine their fitness for advancement.

Hartnett, E. H., asst.-surgeon, granted fourteen days' leave of absence to take effect Jan. 1, 1904, par. 8 S. O., 296, Dept. of the East.

Johnson, R. W., surgeon, ordered to proceed to St. Louis, for duty pertaining to the exhibit of the Medical Department of the Army at the Louisiana Purchase Exposition.

Carroll, James, asst.-surgeon, detailed to represent the Medical Department of the Army at the meeting of the Society of American Bacteriologists, to be held in Philadelphia, Dec. 29-30, 1903.

Usher, F. C. M., asst.-surgeon, granted leave of absence for one month.

Allen, J. H., asst.-surgeon, relieved from further duty in the Division of the Philippines and ordered to U. S. General Hospital, Presidio of San Francisco, for duty.

Chidester, W. C., asst.-surgeon, relieved from duty at U. S. General Hospital, Presidio of San Francisco, and ordered to Fort Lawton, Wash., for duty.

Mathews, Geo. W., asst.-surgeon, granted ten days' leave of absence from Dec. 24, 1903.

Williams, A. W., asst.-surgeon, granted leave of absence for seven days from Dec. 24, 1903, with permission to apply for extension of twenty-three days.

Jean, Geo. W., asst.-surgeon, to proceed to Fort Greble, R. I., for temporary duty during absence on leave of Lieutenant Williams.

Ford, J. H., asst.-surgeon, relieved from duty at U. S. General Hospital, Washington Barracks, D. C., and ordered to Fort Reno, O. T.

Farr, C. W., asst.-surgeon, relieved from duty at Fort Reno, O. T., and ordered to proceed to Fort Mason, Cal., for duty.

Ekwurzel, G. M., asst.-surgeon, relieved from temporary duty at New Haven, Conn., and ordered to Fort Trumbull, Conn., for duty.

Church, J. R., asst.-surgeon, relieved from duty at Fort Trumbull, Conn., and ordered to Fort Brown, Texas, for duty.

Hartsock, F. M., asst.-surgeon, granted ten days' leave of absence.

Patterson, Edwin W., contract surgeon, has been relieved from further duty in the Division of the Philippines, and at the expiration of his three months' leave of absence will report for duty at Fort Washington, Md.

Baily, Howard H., contract surgeon, has been granted a month's leave from the Division of the Philippines, with permission to visit the United States and apply for an extension of two months.

---

[1] See editorial in this issue.

Ekwurzel, Geo. M., asst.-surgeon, ordered to New Haven, Conn., for special duty during the absence of Asst.-surgeon DeWitt.

Hartsock, F. M., asst.-surgeon, arrived in New York City from Peking, China, via Siberia and England.

Ford, Joseph H., Dean, Elmer A., Steer, Samuel L., Truby, Willard F., and Williamson, L. P., asst.-surgeons, promoted captain and asst.-surgeons, U. S. Army, from date.

Crabtree, Geo. H., asst.-surgeon, granted fifteen days' leave of absence.

Van Dusen, Jas. W., asst.-surgeon, leave of absence on account of sickness extended one month.

Shockley, M. A. W., asst.-surgeon, leave of absence extended one month.

Hartsock, F. M., asst.-surgeon, ordered to report to president of examining board at Army Medical Museum Building, Washington, D. C., for examination for promotion.

Kendall, Wm. P., surgeon, ordered to proceed ( in returning to his station) to New York City to consult with the medical supply officer in that city in regard to purchase of instruments and equipment for the new operating room at the U. S. General Hospital, Presidio of San Francisco.

Sabin, Wallace E., contract surgeon, relieved from duty at Fort Lawton, Wash., and ordered to duty in the Philippinne Islands.

Snyder, Calvin D., Baltimore; Cowper, Harold W., Buffalo, N. Y.; Williams, Adrian D., Brooklyn, and Pasco, James B., San Francisco, contract surgeons, ordered to duty in the Philippine Islands.

Chambers, William H., contract dental surgeon, granted twelve days' leave of absence about December 22.

## Navy Changes.

Changes in the Medical Corps U. S. Navy for the week ending Dec. 19, 1903, no orders; for the week ending Dec. 26, 1903, as follows:

McClurg, W. A., medical inspector, ordered to the Bureau of Medicine and Surgery, Navy Department.

Johnson, M. K., surgeon, detached from the Naval Hospital, New York, and ordered to the *Tacoma*.

Schwerin, L. H., A. A. surgeon, detached from the *Southery* and ordered to the *Abarenda*.

Spratling, L. W., surgeon, detached from the *Hancock* and ordered to the navy yard, New York, for special temporary duty at the naval laboratory.

Carpenter, D. N., surgeon, detached from the Naval Hospital, Washington, D. C., and ordered to the *Dixie* for duty with the Panama Marine Brigade.

Spratling, L. W., surgeon, detached from the naval laboratory, Brooklyn, N. Y., and ordered to the *Dixie* for duty with the Panama Marine Brigade.

Angeny, G. L., P. A. surgeon, detached from the Naval Hospital, Philadelphia, Pa., and ordered to the *Dixie* for duty with the Panama Marine Brigade.

## Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ended Dec. 17, 1903.

Bailhache, Preston H., surgeon, detailed to represent the service at the Convention to Consider the Questions Involved in Mosquito Extermination, to be held in New York, December 16.

Irwin, Fairfax, surgeon, granted leave of absence for two days from December 24.

Brooks, S. D., surgeon, to rejoin station at Savannah, Ga.

White, J. H., surgeon, granted leave of absence for five days from December 17.

Carrington, P. M., surgeon, three days' leave of absence from Dec. 15, 1903, under paragraph 189 of the Regulations.

Guiteras, G. M., surgeon, granted leave of absence for three months from December 19.

Perry, J. C., P. A. surgeon, detailed to represent the service at the Convention to Consider the Questions Involved in Mosquito Extermination, to be held in New York Dec. 16.

Greene, J. B., P. A. surgeon, on being relieved at Cleveland by P. A. surgeon H. S. Mathewson, to proceed to Havana, Cuba, for duty in office of U. S. Consul-General, relieving Asst. Surgeon F. E. Trotter.

Mathewson, H. S., P. A. surgeon, relieved from duty at Detroit, Mich., and directed to proceed to Cleveland, Ohio, and assume command of the service at that port, relieving Surgeon J. B. Greene.

Von Ezdorf, R. H., P. A. surgeon, relieved from duty at Laredo, Texas, and directed to proceed to Washington, D. C., and report at Bureau.

Billings, W. C., asst.-surgeon, granted leave of absence for fourteen days from December 13.

Kerr, J. W., asst.-surgeon, to proceed to Ellis Island, New York, and report to Surgeon G. W. Stoner for duty.

Goldberger, Joseph, asst.-surgeon, to report to director of Hygienic Laboratory for duty.

Trotter, F. E., asst.-surgeon, on being relieved from duty at Havana, Cuba, by P. A. Surgeon J. B. Greene, to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters.

Lloyd, B. J., asst.-surgeon, to proceed to Concord Cal., for special temporary duty.

Stimson, A. M., asst-surgeon, granted leave of absence for seven days from Dec. 8, 1903, under paragraph 191 of the Regulations.

Foster, A. D., asst.-surgeon, to proceed to Ellis Island, New York, and report to Surgeon G. W. Stoner for temporary duty.

Ballard, J. C., A. A. surgeon, granted leave of absence for five days from December 24.

Safford, M. V., A. A. surgeon, granted leave of absence for four days from Dec. 14, 1903, under paragraph 210 of the Regulations.

Stearns, H. H., A. A. surgeon, granted leave of absence for fourteen days from December 18.

Maguire, E. S., pharmacist, department letter of November 21, granting leave of absence for thirty days from Nov. 1, 1903, amended so as to read thirty days from December 1.

Gibson, R. H., pharmacist, granted leave of absence for eight days from December 24.

Ryder, L. W., pharmacist, department letter of December 9, granting leave of absence for fifteen days from Dec. 10, 1903, amended to read fifteen days from December 7.

### BOARD CONVENED.

Board convened to meet at Philadelphia, Pa., Dec. 17, 1903, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon Fairfax Irwin, chairman; Asst.-Surgeon W. A. Korn, recorder.

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the two weeks ended Dec. 26, 1903:

### SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 29-Dec. 6, 1 case.

Illinois: Belleville, Dec. 5-12, 1 case; Chicago, Dec. 4-11, 1 case.

Louisiana: Baton Rouge, Nov. 28-Dec. 5, 1 case; New Orleans, Dec. 5-12, 2 cases, imported.

Massachusetts: Boston, Nov. 28-Dec. 5, 1 case; North Adams, Dec. 5-12, 1 case.

Michigan: Port Huron, Dec. 5-12, 1 case.

New Hampshire: Manchester, Dec. 5-12, 2 cases.

New Jersey: Camden, Dec. 5-12, 1 case.

New York: New York, Dec. 5-12, 2 cases.

Ohio: Cincinnati, Dec. 4-11, 4 cases; Dec. 5-12, Dayton, 1 case; Youngstown, 12 cases.

Pennsylvania: Nov. 30-Dec. 12, Altoona, 3 cases; Carbondale, 2 cases; Dec. 5-12, Erie, 3 cases; Johnstown, 3 cases, 2 deaths; McKeesport, 2 cases; Norristown, 1 case; Philadelphia, 67 cases, 16 deaths; Pittsburg, 25 cases, 8 deaths; Reading, Dec. 7-14, 1 case.

Tennessee: Memphis, Dec. 5-12, 20 cases.

Utah: Ogden, Nov. 1-30, 1 case.

Wisconsin: Milwaukee, Nov. 28-Dec. 12, 11 cases.

### SMALLPOX—FOREIGN.

Colombia: Barranquilla, Nov. 22-29, 2 deaths.

Brazil: Rio de Janeiro, Nov. 8-15, 36 cases, 35 deaths.

Ecuador: Guayaquil, Nov. 14-21, 1 death.

France: Lyon, Nov. 14-21, 1 death; Paris, Nov. 21-28, 7 deaths; Rouen, Nov. 1-30, 3 deaths.

Great Britain: Glasgow, Nov. 27-Dec. 5, 20 cases, 3 deaths; London, Nov. 14-28, 10 cases; Nov. 21-28, Manchester, 4 cases; Newcastle-on-Tyne, 1 case, 1 death; Nottingham, 2 cases.

Italy: Catania, Nov. 19-26, 4 deaths.

Mexico: Monclova, Dec. 10, 1 case.

Russia: Nov. 14-21, Moscow, 3 cases, 1 death; St, Petersburg, 59 cases; Warsaw, Oct. 31-Nov. 7, 1 death.

Turkey: Constantinople, Nov. 15-22, 6 deaths.

### YELLOW FEVER—UNITED STATES.

Texas: Laredo, Dec. 8-15, 7 cases, 2 deaths.

### YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Nov. 8-15, 3 cases, 1 death.

Ecuador: Guayaquil, Nov. 21-28, 1 death.

Mexico: Coatzacoalcos, Nov. 28-Dec. 5, 1 case.

### CHOLERA—FOREIGN.

India: Calcutta, Nov. 1-14, 50 deaths.

Japan: Nagasaki, Nov. 10-20, 33 cases, 18 deaths.

Straits Settlements: Singapore, Oct. 24-31, 35 deaths

### PLAGUE—FOREIGN.

Africa: Cape Colony, Oct. 17-24, 2 cases.

Brazil: Rio de Janeiro, Oct. 8-15, 40 cases, 17 deaths.

Egypt: Nov. 7-13, Alexandria, 1 death; Samallut, 1 case, 1 death.

India: Bombay, Nov. 3-17, 103 deaths; Calcutta, Nov. 1-14, 35 deaths; Karachi, Nov. 1-8, 7 cases, 7 deaths.

Japan: Yokohama, Oct. 31-Nov. 7, 1 case, 1 death.

### SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 6-13, 2 cases.

Illinois: Dec. 12-19, Belleville, 2 cases; Danville, 1 case.

Indiana: Evansville, Dec. 12-19, 3 cases.

Louisiana: New Orleans, Dec. 12-19, 3 cases, imported.

Maine: Biddeford, Dec. 12-19, 1 case.

Massachusetts: Haverhill, Dec. 12-19, 1 case.

Michigan: Dec. 12-19, Detroit, 2 cases; Port Huron, 2 cases; Flint, Dec. 6-19, 2 cases.

Mississippi: Natchez, Dec. 6-13, 26 cases.

New Hampshire: Manchester, Dec. 12-19, 1 case.

New Jersey: Camden, Dec. 12-19, 2 cases.

Ohio: Cincinnati, Dec. 11-18, 5 cases, 1 death.

Pennsylvania: Dec. 12-19, Erie, 5 cases, 1 death; McKeesport, 1 case; Philadelphia, 90 cases, 22 deaths; Pittsburg, 27 cases, 8 deaths, 2 imported; Johnstown, Dec. 14-21, 1 case, 1 death.

Tennessee: Memphis, Dec. 12-19, 17 cases.

Wisconsin: Milwaukee, Dec. 12-19, 2 cases.

### SMALLPOX—FOREIGN.

Austria-Hungary: Nov. 21-28, Prague, 7 cases; Trieste, 2 cases.

Belgium: Antwerp, Nov. 21-28, 2 cases, 2 deaths.

Brazil: Rio de Janeiro, Nov. 15-29, 99 cases, 59 deaths.

France: Paris, Nov. 28-Dec. 5, 12 cases.

Great Britain: Birmingham, Nov. 21-Dec. 5, 9 cases; Glasgow, Dec. 4-11, 26 cases, 2 deaths; Nov. 28-Dec. 5, London, 3 cases; Manchester, 1 death; Nottingham, 3 cases; Southampton, 1 case.

India: Bombay, Nov. 17-24, 1 death.

Italy: Catania, Nov. 26-Dec. 10, 6 deaths; Palermo, Noov. 14-21, 1 case.

Java: Batavia, Oct. 21-Nov. 7, 16 cases, 5 deaths.

Mexico: City of Mexico, Nov. 22-29, 1 case, 1 death.

Russia: Warsaw, Nov. 14-21, 6 deaths.

Spain: Corunna, Nov. 21-28, 1 death.

Turkey: Constantinople, Nov. 22-29, 7 deaths; Smyrna, Nov. 15-22, 14 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Cannel, Dec. 13, 1 case; Laredo, Dec. 15-18, 6 cases.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Nov. 22-29, 1 case, 1 death.
Mexico: Vera Cruz, Nov. 28-Dec. 19, 22 cases, 7 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Oct. 31-Nov. 21, 49 deaths.
Straits Settlements: Singapore, Oct. 31-Nov. 7, 24 deaths.
Turkey in Asia: Nov. 16, 116 cases, 114 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Nov. 15-29, 85 cases, 43 deaths.
India: Bombay, Nov. 17-24, 55 deaths; Karachi, Nov. 8-22, 15 cases, 14 deaths.

# Medical Organization.

## Indiana.

Fulton County Medical Society.—At its first annual meeting held in Rochester, December 22, this society completed its organization and elected the following officers: Dr. John M. Ward, Kewanna, president; Dr. Aaron Johnston, Akron, vice-president; Dr. George E. Hoffman, Rochester, secretary; Dr. Charles J. Loring, Rochester, delegate, and Drs. Alphonso Armstrong, Kewanna, and Angus Brown and Milo O. King, Rochester, censors.

Meeting of the Council.—A meeting of the council of the Indiana State Medical Association was held at Indianapolis, December 17. Dr. Albert E. Bulson, Jr., secretary, writes us that the meeting was very successful. It was presided over by Dr. William N. Wishard, Indianapolis, president of the council. Eleven of the thirteen districts were represented, all except two of the councilors being present. In addition to the members of the council there were present Dr. Jonas Stewart, Anderson, and Dr. Frederick C. Heath, of Indianapolis, president and secretary respectively of the state association, and Dr. J. N. McCormack, Bowling Green, Ky., representing the American Medical Association. The reports of the councilors showed that in every district in Indiana, the work of reorganization is progressing rapidly, and that in ten of the districts complete reorganization has been effected. There is no county society in the state that has not shown some gain in membership since the adoption of the reorganization plan. In many counties the gain has been very marked. In several counties in which there has never been a medical organization there is now an active medical society. Taking everything into consideration the reports from the various councilors were very encouraging. Dr. Stewart asked the advice of the council relative to the appointment of delegates to the American Congress on Tuberculosis, which has been advertised to meet in St. Louis early in 1904. After some discussion the council passed a resolution[1] refusing to endorse the said congress. It was the unanimous opinion of the councilors that the Indiana medical profession should not only decline to take any part in this congress, but that it should in no uncertain tone, express its disapproval of the scheme.

## Iowa.

Marion County Medical Society.—This society was reorganized, December 12, with the following officers: President, Dr. Clarence P. Cook, Otley; vice-president, Dr. Gaylord Worstill, Knoxville; secretary, Dr. Corwin W. Cornell, Knoxville; treasurer, Dr. John V. Brann, Knoxville, and delegate, Dr. Benjamin F. Keables, Pella.

Winnebago County Medical Society.—At a business session of this society held at Lake Mills, December 9, the standard constitution and by-laws was adopted, and the reorganization perfected, the following officers being re-elected: Dr. Harry R. Irish, Forest City, president; Dr. Ferdinand A. Ch[illegible]sen, Lake Mills, vice-president; Dr. Luther Wall, Thom[illegible], secretary, and Dr. Gissle M. Lee, Thompson, treasurer.

Adams County Medical Society.—Physicians of the county met at Corning, December 15, and organized a society on the standard plan with the following officers: Dr. W. J. Wallahan, Nodaway, president; Dr. Homer L. Sweet, Mount Etna, vice-president; Dr. Charles H. Bryant, Corning, secretary and treasurer; Dr. Frances E. Potter, Corning, delegate, and Drs. James R. Thompson, Corning, W. F. Stotler, Corning, and William F. Amdor, Carbon, censors.

## Kentucky.

Dr. Arthur T. McCormack, Bowling Green, councilor for the Third District, reports the organization of the following county societies in the mountain section of his district. The organization of these counties gives an active organization in every county in the district except Edmonson, and the only two physicians in that county are members of the Warren County Medical Society. This organization trip covered a distance of about 275 miles, all off the railroad, and through part of the territory the only roads were along creek beds, requiring a week to make the trip.

Monroe County Medical Society.—On November 19 the banner [illegible] p was held in Tompkinsville, and resulted [illegible] of this society. The officers elected were [illegible] ncan, Tompkinsville, president; Dr. J. A. Flippin, Tompkinsville, vice-president, and Dr. Eugene E. Palmore, Strode, secretary-treasurer.

Cumberland County Medical Society.—On November 13 this society was organized in Burksville. The new constitution and by-laws were adopted, and a very strong organization was perfected. The following officers were elected: Dr. Henderson L. Cartwright, president; Dr. Archibald A. Streng, Burksville, vice-president, and Dr. W. Fayette Owsley, secretary-treasurer, all of Burksville.

Metcalfe County Medical Society.—The physicians of Metcalfe County met in Edmonton, November 17, and unanimously adopted the model constitution and by-laws. The society will meet on the third Saturday of each month in the summer and twice during the winter. The officers elected were Dr. John A. Yates, Edmonton, president; Dr. J. H. Owen, Randolph, vice-president; Dr. H. R. Van Zant, Edmonton, secretary-treasurer, and Dr. Zachariah G. Taylor, Knob Lick, delegate.

Allen County Medical Society.—On November 20 the physicians of Allen county met, and after a full discussion reorganized this society. The following officers will attest the health of the new society and promise to help give it a long and active life: Dr. Marcellus W. Whitney, Gainesville, president; Dr. William E. Meredith, Scottsville, vice-president; Dr. Andrew L. Wagoner, Scottsville, secretary-treasurer; Dr. William E. Meredith, Scottsville, delegate to state association, and Drs. John B. House, Scottsville, Hubert M. Meredith, Petroleum, and John E. Pace, Gainesville, censors.

The next aim in this district will be to secure on each county roster the name of every eligible physician within its boundaries. This has already been almost accomplished in several counties. The officers of the county societies authorize the councilor to challenge any other district in the United States to beat them to this goal.

## Maryland.

Cecil County Medical Society.—This society has decided to reorganize on the standard plan at its April meeting.

Anne Arundel County Medical Society.—At a meeting held in Annapolis, December 8, Dr. John Ruhrah, Baltimore, representing the Medical and Chirurgical Faculty of Maryland, delivered an address on "Medical Reorganization."

Kent County Medical Society.—A medical society has been organized in Kent County (Eastern Shore) with Dr. Thomas B. Wilson, Edesville, president; Dr. W. Frank Hines, Chestertown, vice-president, and Dr. H. G. Simpson, secretary-treasurer.

Talbot County Medical Society.—This society was organized at Easton (Eastern Shore), December 17, with the following officers: President, Dr. Julius A. Johnson, Easton; vice-president, Dr. James A. Stevens, Oxford; secretary and treasurer, Dr. Philip Lee, Travers, Easton, and censors, Drs. Samuel C. Trippe, Royal Oak, Charles H. Rose, Cordova, and Joseph S. Garrison, Easton. Dr. Thomas S. Cullen, Baltimore, representing the Medical and Chirurgical Faculty of Maryland, called the meeting to order, outlined the standard plan of organization and recited the essential advantages to be derived therefrom.

# Society Proceedings.

## AMERICAN ROENTGEN RAY SOCIETY.

*Fourth Annual Meeting, held in the University of Pennsylvania, Philadelphia, Dec. 9-10, 1903.*

The President, Prof. A. W. Goodspeed, in the Chair.

### New Officers.

The following were elected to officiate during the ensuing year: President, James B. Bullitt, Louisville, Ky.; vice-presidents, John B. Murphy, Chicago; G. R. Barnes, Buffalo, and Charles L. Leonard, Philadelphia; executive committee, W. W. Johnson, Rochester, N. Y.; Preston H. Hichey, Detroit, and

---

[1] See page 43 of this issue.

Kennon Dunham, Cincinnati. The next place of meeting is to be decided on by the executive committee.

### Pathologic Changes in Tissue Under the Influence of the X-Ray.

Dr. W. S. Newcomet, Philadelphia, said that the changes consists of: 1, degeneration with vascularization of the epithelial pearls; 2, leucocytic infiltration of varying degree, which completes the destruction.

DISCUSSION.

Dr. W. A. Price, Cleveland, Ohio, suggested that possibly *x*-ray tubes possess a variety of powers of penetration, from high to low, and that these rays are active all the time, thus accounting for the various ways in which tissues are affected when subjected to the same technic.

Dr. Henry Hulst, Grand Rapids, Mich., believes that the reaction from the high or low tube is the same, and that the first effect of the *x*-ray is a stimulating one, followed by depression and finally dissolution. *X*-ray activity is dependent on the amount of rays absorbed by the tissue.

Dr. Gordon G. Burdick, Chicago, reduces all his tubes below the line where any rays are given off. He controls the degree of penetration of the ray by the speed with which he drives the cathode stream; this, in turn, is controlled by the electromotive force of the apparatus.

### The Results of the Roentgen Method in the Diagnosis of Renal Calculi.

Dr. Charles L. Leonard, Philadelphia, said the *x*-ray is valuable in differentiating disease of the kidney, especially calculus, as it is accurate, and renders exploratory operation unnecessary. There is less than three per cent. of error. The *x*-ray is a valuable means of diagnosis in cases of appendicitis or oöphoritis.

DISCUSSION.

Dr. James B. Bullitt, Louisville, Ky., cited a case in which the *x*-ray revealed a renal calculus which had been overlooked at the time of operation.

Dr. Henry Hulst, Grand Rapids, Mich., advised compression of the body so as to cut out the secondary rays by lessening the distance between the anode and the plate. Another method that is especially useful in large subjects is inflation of the colon with air.

### Two Cases of Severe X-Ray Necrosis, Presenting Some Unusual Features.

Dr. Clarence E. Skinner, New Haven, Conn., in a paper by this title, drew the following conclusions: 1. Patients who tan well are not immune to burns. 2. The physiologic action of the *x*-light is not confined to the stimulant or destructive influence on the tissues that already exists; it is capable of modifying more or less permanently the developmental functions that control cell growth. 3. The cessation of the pain when the necrotic tissue was shed, proves that this acts as an irritant by developing toxins that act on the peripheral nerve endings. 4. The direct electrical current promulgated healing, therefore galvanism may replace skin grafting. 5. The late appearance of new areas of necrosis may signify that the *x*-ray has a cumulative action. 6. No two cases of *x*-ray burn will react uniformly to the same palliative agent. 7. Patients should not be exposed to the *x*-ray with even a moderate degree of frequency through long periods of time, no matter how well they seem to bear them at first.

Dr. Skinner also reported a case of cervical adenitis treated with the *x*-ray in which there followed a marked growth of hair over those parts of the face and neck that had been exposed to the ray. Similar instances were reported by Drs. Allen, Pancoast, Girdwood, Bullitt and others.

### Skiagraphy of the Chest.

Dr. Henry Hulst, Grand Rapids, Mich., considers this a valuable aid in diagnosis, especially for pathologic detail. The subject must be at rest, and the exposure must be rapid, one second or less sufficing. To secure contrast, the plate may be sandwiched between calcium tungstate screens. The induction coil is preferable to the static machine. The tube must be able to keep its vacuum. The lowest tube that will do the work is the best for this rapid work.

### How to Obtain an Instantaneous Skiagraph of the Thorax.

Dr. Mihran A. Kassabian, Philadelphia, said that the coil is the most important part of the *x*-ray equipment. It should be of twenty inches spark-producing capacity. Next in importance is the interrupter. The electrolytic is the best. A rapid make and break, from 8,000 to 16,000 vibrations per minute, is best. Quick exposures require a rapidly vibrating interrupter. A high vacuum tube having high penetration is necessary. Intensifying screens should be used only when the condition of the patient demands the shortest possible exposure. The plate must be a highly sensitized one.

DISCUSSION.

Dr. G. G. Burdick, Chicago, is in favor of a longer exposure, 15 to 30 seconds. Successful instantaneous skiagraphy is largely dependent on a good plate developer. He prefers amidol, rodinol and metol to hydrochinon.

Dr. P. M. Hickey, Detroit, cautioned against mistaking the shadows of the blood vessels and bronchi for areas of consolidation.

### Localization of Foreign Bodies by the Roentgen Rays.

Dr. W. E. Sweet, Philadelphia, in a paper on this subject, demonstrated his method and exhibited two localizing apparatuses which he uses.

### Care of the Static Machine.

Dr. Henry E. Waite, New York City, said that vapor in the machine is its arch enemy and is best removed with calcium chlorid, after first condensing with ice and salt. Whenever the atmosphere is cold and dry, open the machine widely and allow the plates to revolve slowly for half an hour. The plates are cleaned with kerosene oil, followed by vaselin. The brushes are boiled thoroughly in caustic potash, then rinsed in hot water and dried. All the buttons and sectors are cleaned with the kerosene oil. Do not overlook the glass legs of the platform.

DISCUSSION.

Dr. W. W. Johnson, Rochester, N. Y., prefers the use of well-baked calcium chlorid to remove the moisture, without first condensing the vapor.

Dr. J. C. Pitkin, Buffalo, places common quicklime in the bottom of his machine in a chamber specially built for this purpose so that the machine will not be injured by the lime.

Dr. Wetherill, Philadelphia, in order to determine the presence of moisture, places in his machine a strip of paper moistened with chlorid of cobalt solution.

Dr. G. G. Burdick uses for the same purpose an ordinary ginger cooky, which is a splendid hygrometer. He also exhausts the air from his apparatus, passing it through calcium chlorid before returning it to the machine, thus freeing it from vapor.

Dr. G. P. Girdwood and Dr. W. W. Johnson mentioned instances where, by mistake, carbid of calcium was put into the machine with disastrous results.

### The Trend of Modern Thought on the Subatomic Structure of Matter.

President A. W. Goodspeed, in his annual address, discussed all the theories proposed by various physicists in the field indicated by the title.

### The Development of the Skeleton, Radiographically Considered.

Preston M. Hickey, Detroit, drew the following conclusions: 1. This work is valuable not only from an embryologic and anatomic standpoint, but also from the clinical. 2. The radiograph offers a means for studying the formation of the bones, joints and epiphyses. 3. The statements in the text-books on anatomy regarding bone development are wrong, and should be revised according to the knowledge gained by the radiograph. 4. Reproduction of fetuses at different ages should be inserted in text-books on anatomy. 5. For diagnostic purposes radiographs of an injured joint should always be compared with the normal joint.

DISCUSSION.

Dr. G. P. Girdwood, Montreal, Canada, called attention to the fact that these radiograph studies of the fetus are also of medicolegal importance in determining the age of the fetus.

**Dr. James B. Bullitt** of Louisville suggested that a complete radiographic atlas of growing bones and joints would be of great value to the surgeon as well as to the anatomist.

### Technic for Making Good Dental Skiagraphs.

**Dr. Weston A. Price**, Cleveland, Ohio, prefers for this purpose a large coil, a Wehnelt interrupter and a tube that will show the bones of the hand white and transparent. He uses a special film of very flexible celluloid which is covered with a waterproof and lightproof material (unvulcanized black dental rubber, calendered thin). This film can not be either bent, broken or scratched.

### Developers.

**Dr. Gordon G. Burdick**, Chicago, recommended the following developers: *Solution A.:* Metol and ortol 15 grams each; potassium metabisulphate, 8 grams; potassium bromid, 1 gram; distilled water, 1,000 grams. *Solution B.:* Sodium sulphite, dry 40 per cent., and sodium carbonate, dry 60 per cent. in water, 1,000 grams. Use 30 c.c. of each solution and dilute with water according to the effect desired. The less water the more contrast; the more water, the softer the negative.

DISCUSSION.

**Dr. Kassabian** said that the trouble lay in the fact that operators fail to become thoroughly familiar with some one developer. They are all good, but must be used properly to produce good results.

**Dr. Dieffenbach**, New York City, prefers edinol, a salt of metol.

**Dr. Russell H. Boggs**, Pittsburg, in a paper on "Accuracy in X-Ray Diagnosis," favored a developer of: Edinol, 1 dram; sodium sulphate, 10 drams; sodium carbonate, 2 drams; water, 10 ounces.

The subject of "Collapsing Tubes" was considered by **Dr. H. K. Pancoast** and others. The belief was expressed that such an occurrence is due to the fact that some tubes are not annealed before being offered for sale.

### Dangers to the X-Ray Operator.

**Dr. John C. Pitkin**, Buffalo, described very vividly the *x*-ray burn and its attendant symptoms. He advised the wearing of protecting gloves, glasses and office coat; and that the operator remain out of the field of the *x*-radiation as much as possible while the tube is excited.

DISCUSSION.

**Dr. W. A. Price** exhibited a flexible rubber cloth that is a suitable protection against the *x*-ray. He suggested the possibility of a cumulative action of the *x*-ray which might evidence itself later in life. He also showed a non-conducting protective tube holder.

**Dr. James A. Marsh**, and others, called attention to the fact that the room and its contents become charged with secondary rays which may cause a burn on any part of the body which is not exposed to the direct ray.

In discussing the treatment of *x*-ray burn, it was shown that there is one remedial agent that is effective in all cases. In some instances, boric acid, lanolin and resorcin were effective; in others the exclusion of light, and in still others remedies such as are used in the treatment of the ordinary skin lesions, to which, however, the *x*-ray burn does not bear the slightest resemblance either etiologically or pathologically. It is as varied in its manifestations as is eczema.

Other papers were read by Dr. Kennon Dunham, Cincinnati, on "The Effect of Rays on Lower Animal Life"; by Dr. Henry K. Pancoast, Philadelphia, on "The Therapeutic Effect of the X-Rays," and by Mr. Martin Wilbert, on "A Comparative Study of Fractures of the Extremities."

---

## INTERNATIONAL SANITARY CONFERENCE.

*Held at Paris, Oct. 10 to Dec 3, 1903.*

The International Sanitary Conference of Paris, 1903, was called by the government of the French Republic, at the instance of the government of Italy, for the twofold purpose of (1) consolidating into one text the decisions of the conventions of Paris, 1893, and Venice, 1897, and (2) of revising existing sanitary conventions in accordance with the advances of modern scientific research.

### Delegates.

The following powers were represented by delegates: Germany, Argentine, Austria-Hungary, Belgium, Brazil, Denmark, Spain, United States, France, Great Britain, Greece, Italy, Luxemburg, Montenegro, Holland, Persia, Portugal, Roumania, Russia, Sweden and Norway, Servia, Switzerland and Turkey. Two powers, Mexico and Japan, were not represented.

In general, the delegation from each country consisted of diplomats and technical delegates. The diplomatic representatives were of course well known to each other and in their respective circles, and many of them had been in attendance on the Venice Conference of 1897. Among the technical delegates were to be noted Gaffky of Giessen and Nocht of Hamburg; Daimer and Kobler of Austria-Hungary; Beco and Voituron of Belgium; Cortezo y Prieto of Spain; Brouardel, Proust and Roux of France; Theodore Thomson, Clemow and Richardson of Great Britain, the last representing British India; Santoliquido of Italy; Ruijsch, Stekoulis and Plate of Holland; Panayote Bey of Persia; Silva Amado of Portugal; Cantacuzene and Talashesco of Roumania; d'Anrep, Karacanovsky and Samaskine of Russia; Wawrinsky of Sweden and Norway; Schmid of Switzerland; Duca Pacha of Turkey; and Ruffer of Egypt. The delegates of the United States were all technical and were Col. William C. Gorgas, assistant surgeon-general, U. S. A.; Assistant Surgeon-General H. D. Geddings, U. S. Public Health and Marine-Hospital Service; and Medical Inspector Frank Anderson, U. S. Navy.

The conference was called to order by M. Delcassé, minister of foreign affairs of France, who welcomed the delegates on behalf of the republic and the president. M. Camille Barrère, ambassador of France at Rome, was elected president of the conference, and M. Rocco Santoliquido, director-general of the public health of Italy, was chosen vice-president. The president made an eloquent and instructive address, and announced the corps of secretaries, and his address was responded to by the vice-president on behalf of the conference.

The conference at this meeting resolved itself into three great commissions, a technical under the chairmanship of Santoliquido; ways and means under the chairmanship of Barrère, and codification with Beco as chairman. On behalf of the United States Geddings acted on the technical, Gorgas on the ways and means, and Anderson on the codification, though every member of the conference had the privilege of attending the meetings of each commission.

In addition, the technical commission chose from among its numbers a subcommission of fifteen technicians, to whom were referred all questions of a purely scientific and technical nature. The sessions of this subcommission and of the technical commission were animated, lively, and at times almost stormy.

At the conclusion of the transactions of the technical subcommission Roux presented a report which was a masterpiece, and on behalf of the commission Proust presented an admirable report.

After the third plenary session there was a lengthy recess, as about this time the king and queen of Italy arrived in Paris as the guests of the French Republic. At the conclusion of this event, the meeting place of the conference was transferred to magnificent apartments at the ministry of foreign affairs, and meetings of the various commissions were held from day to day, with frequent recesses for private consultation and to give opportunity to delegates to communicate with their respective governments for instructions on points of practice and questions of policy as they arose. In the meantime many social attentions were conferred on the delegates.

At last the reports of the various commissions were completed, presented to plenary meetings of the conference and a tentative convention was prepared, which, after a recess of ten days, received signature on December 3.

During the conference occurred the sudden death of Prof. Adrian Proust, inspector-general of the sanitary service of

France, a distinguished sanitarian and one of the most conspicuous figures in the conference and its transactions. He was stricken with apoplexy while in the discharge of his duties at the Faculté de Médecine, and died November 26. The loss to the conference, to sanitary science and to France was a severe one, and the grief of the conference and the respect of its members for the deceased were manifested by the attendance of the conference as a body at the funeral ceremonies.

### Accomplishments of the Conference.

1. A clearer view of plague and cholera was reached.
2. The convention report as signed represents the latest advances in the scientific investigation of plague; the period of incubation of the disease has been accepted as the period of observation, thus reducing to a minimum the hardships to be imposed on passengers.
3. An emphatic declaration has been made that merchandise is dangerous from the point of view of conveying plague, only when contaminated with pest products or harboring plague-stricken rats.
4. The rôle of the rat in the dissemination of plague has been very fully canvassed and the danger from the rodents fully recognized. Special attention has been paid to methods for their destruction in both empty and laden vessels.
5. Previous convention reports have been edited and codified, and inconsistencies and contradictions removed.
6. A much more calm and dispassionate feeling now exists as to the danger from plague. The disease is not lightly regarded, but has been robbed of much of its traditional terror.
7. While a proposition for the establishment of an international sanitary bureau does not form an integral part of the report, the formation of such a bureau will be urged on the signatory power through regular diplomatic channels.
8. The methods of disinfection of ships and merchandise as recommended in the reports and prescribed in the convention are modern, reasonable and effective.

A most gratifying feature of the conference is that the sanitary system of the United States is now more thoroughly understood and better appreciated abroad than ever before. The essentially American work of the sanitation of Havana and other Cuban cities, the abolition of yellow fever from the island, and the demonstration of the rôle of the mosquito in the transmission of the disease were subjects for unstinted praise, and the example of the United States was recommended to other countries for their guidance and emulation.

But the picture thus drawn has a reverse side. It was found impossible to obtain the signature of the Turkish delegates to the convention. No measure was proposed to which they did not make numerous reservations, and on the date of the signature, in addition to their reservations, they filed a general protest in the whole matter of the regulation of pilgrimages and the betterment of the sanitary situation under the control of the Ottoman government on the Red Sea and Persian Gulf. So long as the Ottoman government maintains this attitude it will be difficult to obtain the full benefit of the convention, and it remains to see what diplomatic representation will do.

## BOSTON SOCIETY OF MEDICAL SCIENCES.

*Meeting held Dec. 15, 1903.*

### The Etiology of Scarlet Fever.

Dr. F. B. Mallory of Harvard Medical School and of the pathologic department of the Boston City Hospital, read a paper on this subject, stating the results of his research in a series of cases and his discovery of certain protozoa in the skin of the patients. Bodies made up of a granular substance, with a firm reticulum, and in some cases one or more vacuoles, and in size 2 to 7 microns in diameter, were made out. There was a second group of radiate bodies, 4 to 6 microns in diameter, having a central body and 10 to 18 segments arranged about it. These definite rosettes with numerous segments "are closely analogous to the series seen in the asexual development (schizogony) of the malarial parasites, but in addition there are certain coarsely reticulated forms which may represent stages in sporogomy or be due to *degeneration of the other forms.*" Later these segments separate from each other, but still maintain a relation to the central body.

Both groups stain well with methylen blue. Both are found in the epithelial cells of the epidermis, between these cells, in the superficial lymph spaces and in the spaces of the corium, but nowhere else.

Dr. Mallory pointed out the marked resemblance to the malarial parasites, illustrating by microscope and lantern slides. He has found the organisms in only four cases. Skin from early cases failed to show the parasite.

"In conclusion," said Dr. Mallory, "I wish to say that while I personally believe that these bodies are protozoa and have an etiologic relation to scarlet fever, I am far from claiming that such a relation has been proved."

### Shape of Blood Corpuscles.

Dr. Frederick I. Lewis, a worker in the histologic laboratory of Harvard, stated his belief that the theory of a globular or bell-shaped red blood corpuscle, instead of the universally accepted biconcave disc as the normal shape of that corpuscle, has been found by certain experiments made by him in his work there.

The meeting concluded with an exposition of "Radium," illustrated by specimens, by Dr. Francis H. Williams.

## SOUTHERN MEDICAL COLLEGE ASSOCIATION.

*Annual Meeting, held at Atlanta, Ga., Dec. 14, 1903.*

This meeting was a very satisfactory one, and the consensus of opinion was that ultimately there will be nothing in the way of amalgamating the Southern Medical College Association with the Association of American Medical Colleges. The following colleges were represented: Medical College of Virginia, Dr. C. Tompkins; Medical Department of University of Nashville, J. D. Jacobs; Medical Department of Vanderbilt University, G. C. Savage; Medical Department of University of the South, J. S. Cain; Birmingham Medical College, J. C. LeGrande; Medical Department of Fort Worth University, Bacon Saunders; Medical Department of University of Tennessee, Dr. R. O. Tucker; Medical Department of Baylor University, J. M. Rosser; Tennessee Medical College. Knoxville, Charles P. McNabb; Medical Department of University of Mississippi, J. B. Bullitt.

The president, in his address, recommended that still further advancement be made in the way of preliminary requirements. and there was an amendment to the constitution offered with that in view, this amendment requiring two years in the high school. An amendment to the constitution was adopted requiring that forty-one months shall intervene between matriculation for the first course and the date of graduation, and requiring that eleven months shall intervene between the matriculation for any one course, and the matriculation for the next succeeding course.

The Memphis Hospital Medical College applied for readmission into the association, and the application was laid over for one year, according to the constitution.

### New Officers.

The officers for the ensuing year are: Dr. C. Tompkins, president; Dr. Bacon Saunders, vice-president; Dr. G. C. Savage, secretary-treasurer; Drs. J. S. Cain, L. C. LeGrande and James M. Rosser, executive committee.

## SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Sixteenth Annual Session, held in Atlanta, Ga., Dec. 15-17, 1903.*

Under the presidency of Dr. J. Wesley Bovée, Washington, D. C.

An address of welcome was delivered by Mayor Evan P. Howell, which was responded to by Dr. George Ben Johnston. After a brief report by the chairman of the local committee of arrangements, Dr. Willis F. Westmoreland, the reading of papers was begun.

### A Study of the Prostate and Treatment of Prostatic Hypertrophy.

Dr. G. Wiley Broome, St. Louis, concluded that: 1. The normal position of the urethra is in the floor of the bladder; in urinary obstruction it is always elevated from one to two inches above the floor. 2. Normally, there is no third lobe; but segmentation takes place behind the prostatic fissure in consequence of a hyperplastic process, this process occurring in the direction of least resistance—into the cavity of the bladder. 3. In only a small percentage of cases is a hypertrophied prostate responsible for urinary obstruction. 4. No matter how large the prostate becomes, it will retain its functionating capacity. It is not the organ which causes suffering. 5. By prostatectomy this functionating organ is mutilated or destroyed, and the bladder, which really causes the patient trouble, is left *in situ* without any operation on it. 6. In only a small percentage of cases can the prostate be enucleated. 7. Routine prostatectomy for urinary obstruction is wrong. 8. The commissure and capsule are obliterated in the fibromyomatous variety of prostate. In the adenomatous variety, if complete and permanent drainage is established, the prostate will shrink.

DISCUSSION.

DR. C. H. MAYO, Rochester, Minn., said he had operated by the median perineal method in over thirty cases by the Goodfellow technic, and had been much pleased with the method and results.

DR. W. P. CARR, Washington, D. C., had seen only one case in which there was any difficulty in peeling the prostate out of its capsule. Prostatectomy in healthy men has a very small mortality; but when an infected bladder, Bright's disease or atheromatous arteries exist, it is a serious operation.

### Edematous Encephalitis.

DR. W. P. CARR, Washington, D. C., called attention to a brain condition frequently encountered when operating for cerebral epilepsy and for suspected cerebral abscess following postgrippal mastoid disease. Drainage gave much benefit. He reported four cases. It is impossible to say, in most cases, whether the edematous encephalitis is caused by injury or by the influenza poison, or whether it is a lesion of epilepsy. He had found no cases in the literature in which edema was noted as a marked feature. In cases of severe cerebral symptoms following influenza or blows on the head, if the symptoms persisted or became worse after weeks of medical treatment, he thought exploration justifiable.

After making an osteoplastic flap, if there is an edematous appearance, a grooved director should be introduced into the brain substance carefully in several places, and the serum drained off until the brain assumed a normal appearance. A small soft drainage tube should be inserted into the arachnoid space and left while a copious discharge of serum continued.

DISCUSSION.

DR. C. H. MAYO said that he and his brother had operated on many cases of epilepsy and traumatic insanity, and he could corroborate what the essayist had said regarding edematous encephalitis. Drainage is the best treatment.

### A New Device and Method for Intestinal Anastomosis.

DR. W. P. CARR also presented a method of intestinal union by small silver clamps; he thought it easier, quicker and more free from objectional features than the Murphy button. The inverted edges of the gut are clamped from the inside. He had used the clamps on one man who recovered.

DISCUSSION.

DR. I. S. STONE, Washington, D. C., discussed cases of retention of the Murphy button, and announced his intention to try Dr. Carr's device.

DR. GUY L. HUNNER, Baltimore, and DR. J. GARLAND SHERRILL, Louisville, Ky., advocated suturing in preference to all mechanical devices.

### The Surgical Physiology of the Lymphatic System.

DR. C. H. MAYO, Rochester, Minn., said that a study of the lymphatic system readily explained many normal physiologic as well as pathologic processes. The subject is deservedly receiving more attention from surgeons. The system is constantly engaged in maintaining nutrition as well as defense against pathologic processes. He described the struggle in glands between infection and leucocytes. The interior of the brain is deficient in lymphatics, the arachnoid serving this purpose on the surface. Hemorrhages into its structure become cysts from lack of absorption, and infections cause little temperature or general disturbance except from pressure. The liver and kidney show the same condition in a less marked degree. The lungs, rich in lymphatics, give constant temperature from infectious diseases. Chills usually signified the direct delivery of accumulations of infection into a vein. There is, therefore, a real principle involved in drainage, whether it be internal or external. He classified drainage thus: 1. Rest by splints, pressure, dressing or bed, to quiet the circulation. 2. Elevation to reduce arterial supply and favor venous and lymphatic return. 3. Massage to break up coagulated exudates and enable the lymph vessels to remove the exuded material. 4. Moist dressings favor the escape of exudate from open wounds and also favor the lymphatic circulation in closed injuries. 5. Adjuncts to drainage in the use of solutions having affinity for moisture acting by osmosis, as glycerin or alcohol. 6. Wound drainage by the open method with or without secondary suture. 7. Incision. 8. Wicks, gauze, etc., as mechanical aids.

### Early Diagnosis of Cancer of the Uterus.

DR. F. F. SIMPSON, Pittsburg, Pa., said that to the average practitioner cancer is rare compared with other afflictions, but as a cause of death its frequency is appalling. Statistics show that 1 out of every 14 people who reach the age of 30 dies of cancer. Out of every 28 women who pass the age of 30 cancer kills 1. The paper was largely statistical, and the author closed by predicting that well-informed women of the cancer age would seek protection by regular quarterly examinations. Early diagnosis would then be the rule in cancer of the uterus, as it is now in appendicitis.

### Fracture-Dislocation of the Spine.

DR. J. SHELTON HORSLEY, Richmond, Va., reviewed the authorities and called attention to the fact that without an operation or a postmortem it was impossible to tell by symptoms alone whether the cord was completely destroyed. He advocated the plan of McCosh, to operate in all cases of complete paralysis below the injury unless there was improvement within twenty-four hours. The danger of delay lies in degenerative changes in the spinal cord which set in soon after the injury. Early operation might arrest this degeneration. He reported six cases.

(*To be continued.*)

---

## Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Bronchorrhea.

In bronchorrhea the following combinations are recommended by Danforth in *Amer. Text-Book of Applied Ther.*:

℞. Copaibæ ........................gtt. xx 1|30
Pulv. opii ........................gr. ii |12
Pulv. acaciæ q. s.
M. Ft. capsulæ No. x. Sig.: One every three hours; or:
℞. Copaibæ ........................gr. xx 1|30
Acidi gallici ........................gr. xxx 2|
Pulv. acaciæ q. s.
M. Ft. cap. No. x. Sig.: One every three hours.

### Amebic Dysentery.

Amebic dysentery can be cured, according to S. G. Gant, in *Amer. Med.*, by medication through the bowel alone. During the first week the bowel is irrigated daily through a long colon tube with a solution containing grains thirty (2.00) of silver nitrate to the pint of water. During the second week grains twenty (1.30), the third week grains ten (.65) are used and continued for the next two weeks, alternating with the following emulsion given per rectum:

| | | | | |
|---|---|---|---|---|
| ℞. | Iodoformi | ʒii | 8 | |
| | Bismuthi subnitratis | ʒiv | 15 | |
| | Olei olivæ | Oi | 500 | |

M. Sig.: To be used as an injection by the bowel once daily.

The silver solution is then stopped and the emulsion alternated with the following combination:

| | | | | |
|---|---|---|---|---|
| ℞. | Sodii biboratis | ʒii | 8 | |
| | Ext. krameriæ flu. | ℥iv | 120 | |

M. Sig.: Two tablespoonfuls to be added to a pint of water and injected by the bowel once daily. For a week the diet should consist of large quantities of unsalted butter and baked potatoes. The patient may at the end of this period be given a chop, unsalted butter, baked potatoes, eggs and milk.

### Pruritus Vulvae.

The following combinations are recommended by Beall, in *Merck's Archives*, in the treatment of pruritus of the vulva:

| | | | | |
|---|---|---|---|---|
| ℞. | Menthol | gr. iv | | 25 |
| | Quininæ sulph. | gr. x | | 65 |
| | Acidi carbol. | gr. xii | | 75 |
| | Ung. hydrarg. nitratis | ʒss | 2 | |
| | Ichthyol | ʒi | 4 | |
| | Liq. petrolati | ʒiii | 12 | |
| | Ol. ricini | ʒv | 20 | |

M. Sig.: Apply freely after washing the parts with hot water; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Cocainæ hydrochlor. | gr. v | | 30 |
| | Tinct. eucalypti | gtt. xlv | 3 | |
| | Chloralis hydratis | gr. xxxv | 2 | 30 |
| | Aquæ destil. q. s. ad | ℥iv | 120 | |

M. Sig.: Apply as necessary to stop the itching.

### Acute Bronchial Catarrh.

There is no remedy, according to Yeo, in his *Clin. Ther.*, which so readily relieves the distressing dryness of the mucous membrane in the early stages of acute bronchitis as does tartarized antimony. He recommends it combined with small doses of morphin, codein or opium as follows:

| | | | | |
|---|---|---|---|---|
| ℞. | Vini antimonialis | ʒiss | 6 | |
| | Liquoris morph. acetatis | ʒss | 2 | |
| | Liq. ammonii acetatis | ℥iss | 45 | |
| | Aq. laurocerosi | ʒii | 8 | |
| | Syrupi simp. | ʒiii | 12 | |
| | Aquæ q. s. ad | ℥vi | 180 | |

M. Ft. mistura. Sig.: Two tablespoonfuls every three or four hours.

The following combination is sometimes used by the author as a substitute for the foregoing prescription:

| | | | | |
|---|---|---|---|---|
| ℞. | Pulv. opii et ipecacúanhæ | gr. v-x | | 30-.65 |
| | Spts. etheris nitrosi | ʒi | .4 | |
| | Liq. ammon. acetatis | ʒiii | 12 | |
| | Aq. camphoræ | ℥iss | 45 | |

M. Sig.: At one dose, to be taken at bedtime, followed the next morning by a saline purgative.

When fever is present the following is of great value:

| | | | | |
|---|---|---|---|---|
| ℞. | Tinct. aconiti | m. xxiv | 1 | 65 |
| | Vini antimonialis | ʒii | 8 | |
| | Liq. morph. acetatis | m. xl | 2 | 65 |
| | Liq. ammon. acetatis | ℥iss | 45 | |
| | Aq. camphoræ q. s. ad | ℥viii | 240 | |

M. Ft. mistura. Sig.: Two tablespoonfuls every two or three hours.

It should be kept in mind, however, when opium, antimony and aconite, or similar preparations are given, that they should be discontinued when the definite symptoms for which they are given have disappeared.

As a stimulating expectorant the following combination is recommended:

| | | | | |
|---|---|---|---|---|
| ℞. | Infusi senegæ | ℥iii | 90 | |
| | Sodii bicarb. | ʒi | 4 | |
| | Sodii chloridi | | | |
| | Ammon. carb., āā | gr. xxiv | 2 | 65 |
| | Syr. tolutani | ʒiii | 12 | |
| | Aquæ q. s. ad | ℥vi | 180 | |

M. Ft. mistura. Sig.: Two tablespoonfuls every six hours.

Dr. N. S. Davis recommends the following mixture in acute bronchitis:

| | | | | |
|---|---|---|---|---|
| ℞. | Tinct. veratri viridis | ʒiss | 6 | |
| | Vini antimonii | ʒiv | 24 | |
| | Tinct. opii camph. | ℥iiss | 75 | |
| | Liq. ammon. acetatis | ℥ii | 60 | |

M. Ft. mistura. Sig.: One teaspoonful in a tablespoonful of water every two, three or four hours.

| | | | | |
|---|---|---|---|---|
| ℞. | Ammon. carb. | gr. xxx | 2 | |
| | Tinct. hyoscyami | ʒiv | 15 | |
| | Codeinæ | gr. ii | 12 | |
| | Syr. pruni virg. | ʒiv | 15 | |
| | Aquæ camphoræ q. s. ad | ℥ii | 60 | |

M. Sig.: One teaspoonful every three hours.

E. Fletcher Ingals recommends the following combination to relieve the cough:

| | | | | |
|---|---|---|---|---|
| ℞. | Ext. cannabis indicæ | gr. ⅛ | | 008 |
| | Ext. hyoscyami | gr. ss-i | | 03-.06 |
| | Ext. nucis vom. | gr. ¼-ss | | 015-.03 |
| | Quininæ hydrobrom. | gr. i-ii | | 06-.12 |
| | Camphoræ monobrom. | gr. ii-iii | | 12-.20 |

M. Ft. capsulæ No. i. Sig.: One such capsule every four to six hours; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Morphinæ sulph. | gr. i | | 06 |
| | Ammon. carb. | gr. xxx-ʒi | 2-4 | |
| | Syr. pruni virg. | | | |
| | Mist. glycyrrhizæ co., āā | ʒiv | 15 | |

M. Sig.: One teaspoonful in water and repeat as necessary.

He condemns the use of morphin in the capillary form of bronchitis except in very small doses. Ammonium chlorid or ammonium carbonate are useful preparations in this form of bronchitis; or a combination of the carbonate and iodid is of value:

| | | | | |
|---|---|---|---|---|
| ℞. | Ammon. carb. | ʒii | 8 | |
| | Ammon. iodid. | ʒiii | 12 | |
| | Syr. glycyrrhizæ | | | |
| | Syr. tolutani, āā | ℥ii | 60 | |

M. Ft. mistura. Sig.: One teaspoonful every two or three hours in water.

Stevens, in *Med. Rev. of Reviews*, recommends the following treatment of acute bronchitis:

| | | | | |
|---|---|---|---|---|
| ℞. | Terebeni | | | |
| | Ol. eucalypti, āā | ʒss | 2 | |
| | Strych. sulph. | gr. 1/3 | | 02 |
| | Codeinæ sulph. | gr. iii | | 20 |

M. Ft. capsulæ No. xii. Sig.: One capsule every four hours.

The following is recommended by De Brun in the treatment of chronic bronchitis:

| | | | | |
|---|---|---|---|---|
| ℞. | Ichthyol | gr. xxx | 2 | |
| | Glycerini | | | |
| | Syr. aurantii, āā | ʒiv | 15 | |
| | Aquæ | ℥iii | 90 | |

M. Sig.: One half to one teaspoonful several times daily.

### Acute Peritonsillitis.

Shurley, in his "Dis. of Throat and Nose," recommends, in the treatment of acute peritonsillitis, that the patient be given a brisk cathartic, either mercurial or saline in conjunction with hot bathing. Ice should be applied externally and the patient should be instructed to hold bits of ice in the mouth. Local applications by means of spray or pigment of turpentine or carbolic acid and glycerin or insufflations of iodoform are recommended. He advises, however, hot applications locally after the disease has become well established, in order to favor suppuration. Applications of steam to the throat or hot gargles of slippery elm tea will promote suppuration; the pain is so severe as a rule, however, that the attempt at gargling will produce harm rather than good. Throughout the course of the disease a spray of a 2 to 4 per cent. solution of cocain will be of great value in relieving the intense suffering of the patient. When suppuration has taken place opening the abscess is in order, first locating, if possible, the seat of the pus by introducing the finger into the pharynx.

E. F. Ingals states that the disease may be aborted in about one case in four by applying to the inflamed gland once or twice a day a solution of silver nitrate, gr. 60 (4.00) to the ounce (30.00), two or three applications usually being sufficient. The value of local applications of guaiacol should be emphasized in the treatment of this painful condition, applied at any stage of the disease, with the assurance that excellent results will be obtained, as in almost every case the swelling becomes reduced and the patient will be enabled, after one or two applications, to open the mouth wider and with less pain, and he will also be able to take nourishment, which may not have been done previously on account of the extreme pain. Guaiacol should be applied by the physician himself, taking care not to let any of the solution drop into the pharynx or larynx. The following strength solution should be applied at first, and the strength gradually reduced as the patient improves:

| | | | | |
|---|---|---|---|---|
| ℞. | Guaiacol | | | |
| | Olei olivæ, āā | ʒii | 8 | |

M. Sig.: Apply locally, by means of a cotton swab, twice daily.

Internally the tincture of aconite or tincture of opium may be given in small and oft-repeated doses and less frequently as the subjective symptoms subside. Codein in doses of gr. 1/3 (.02) to 1/2 (.03) is of service, repeated every three hours in order to relieve the pain and allow the patient to sleep.

### Nutritive Enema.

The following formula is recommended by *Rev. francaise de Méd. et de Chir.* as a suitable combination for nutrient enemas:

| | | | | |
|---|---|---|---|---|
| ℞. | Liq. peptones | ℥ii | 60 | |
| | Eggs, 1 to 3. | | | |
| | Sol. glucose (20 per cent.) | ℥iii | 90 | |
| | Sodii chloridi | gr. xxiiss | 1 | 50 |
| | Pulv. pepsini | gr. viiss | | 50 |
| | Tinct. opii | gtt. iii | | 20 |
| | Bouillon | ℥vi | 180 | |

M. Sig.: For one enema.

### Chronic Orchitis and Traumatic Inflammations.

The following has been recommended in the treatment of such cases of orchitis as have become chronic, also of inflammatory conditions arising from traumatism:

| | | | |
|---|---|---|---|
| ℞. | Ichthyol | ʒii | 8 |
| | Plumbi iodidi | gr. xv | 1 |
| | Ammon. chloridi | gr. xxx | 2 |
| | Liq. petrolati | ℥ii | 60 |

M. Sig.: Apply locally on lint.

### Treatment of Puerperal Infection.

The treatment of puerperal infection does not differ essentially from the treatment of sepsis from a surgical operation, according to J. H. Burtenshaw, in *Internat. Med. Magazine.* The treatment, according to this author, should consist in: 1, removing the source of infection; 2, neutralizing the effects of the septic germs or their toxins; supporting the patient's vitality. He condemns the use of the sharp curette in relieving the uterus of its contents, preferring the finger or a dull wire curette in order not to abrade the endometrium. Lacerations of the vaginal walls and cervix should be cauterized with pure carbolic acid and the cavity of the uterus and the vagina should be irrigated with two gallons or more of normal saline solution or a 1 per cent. solution of lysol, after which these cavities should be packed with iodoform gauze and replaced by a similar packing after twenty-four hours. After removing the second packing the uterus should be left alone. He prefers the iodoform to alcohol or formalin tampons. A suppository containing fifteen (1.00) grains of iodoform may be introduced into the uterus, followed by a packing of plain sterilized gauze, and repeat once the following day. In his opinion the value of continuous irrigation in these cases is overestimated because of the fact that the pathogenic organisms are situated too deeply in the tissues.

To neutralize the effects produced by the germs or their toxins, elimination must be promoted by careful attention to the bowels and kidneys. The saline solution is of value in aiding elimination. In puerperal sepsis, especially, does the protoplasm of the leucocytes show marked affinity for iodin, consequently the author recommends Pryor's method of opening the posterior cul-de-sac and packing the pelvic cavity with a 10 per cent. iodoform gauze. The value of unguentum Credé, in the author's experience, is very limited in the treatment of puerperal sepsis.

To support the patient the diet must necessarily be nourishing, and at the same time concentrated, consisting of peptonized milk, malted milk, egg albumin, calvesfoot jelly, meat extracts, and later, when the temperature has fallen, the patient should be given alcohol as a food. In the way of medicines he recommends ergot, strychnia nitrate from the commencement of the attack. The temperature should be controlled with tepid or cold sponging followed by an alcohol rub and repeated as necessary.

## Medicolegal.

**No Damages Recoverable for Bodily Disfigurement.**—The Branch Appellate Court of the First District of Illinois holds, in Lake Street Elevated Railroad Company vs. Gormley, that the marring of personal appearance and humiliation from contemplation of bodily disfigurement are not elements entering into the computation of pecuniary damages for personal injuries sustained by reason of alleged negligence.

**Eleven Thousand Dollars Damages Allowed for Rupture.**—The Appellate Court of Illinois for the First District holds, in City of Chicago vs. Gillett, that a judgment for $11,000 damages should not be disturbed because of its amount where a man 44 years of age who had been earning $70 to $75 a month sustained a severe rupture from falling through a defective sidewalk, the evidence showing that the rupture was in the neighborhood of 22 inches around, had caused suffering day and night during the two years and a half up to the time of the trial, that it had to be supported by a leathern bag or pouch, incapacitated him for manual labor of any consequence, was entirely irreducible, and was likely to grow worse.

**Casualty Company Not Liable—Death from Eating Unsound Oysters.**—The Supreme Court of Texas, in the case of the Maryland Casualty Company vs. Hudgins, takes a different view from that of the Court of Civil Appeals, reported on page 1395 of THE JOURNAL, May 16, 1903, of the construction to be placed on a policy of accident insurance which provided that it did not cover "injuries, fatal or otherwise, resulting from poison, or anything accidentally or otherwise taken, administered, absorbed, or inhaled," the insured having died from eating unsound oysters. It holds that the plain meaning of the language used was that the company accepted from its liability all injuries which might arise from whatever thing of any kind or character, poisonous or not, the insured might voluntarily and consciously take into his stomach—that is, to swallow as food or drink; that the death of the insured was caused by means within the exception from liability contained in the contract of insurance, and that no cause of action was or could be shown against the company on that contract. As to the claim that, while the eating of the oysters was not accidental, the eating of spoiled oysters was accidental because the insured did not intend to eat unsound oysters—the accident consisting in the state of the thing swallowed, the Supreme Court pronounces that a shadowy distinction. But, admitting it to be sound, it says that it did not take the case out of the exception; for the spoiled oysters was a thing, it was "taken," from which the injury resulted, which brought the case under the exception, and took it out of the obligation of the contract.

**Qualification Presumed—Right to Sue for Services.**—The Appellate Court of Illinois for the Second District says, on the appeal of the County of Jo Daviess vs. Staples and others, an action brought by the latter to recover for the performance of a surgical operation on a resident of East Dubuque, Ill., taken therefor to a hospital in Dubuque, Iowa, that it was averred that the parties suing were "legally qualified to practice medicine and surgery at the time when and place where said services were rendered." As just stated, the services were rendered in Iowa. There was no proof whether the statutes of Iowa required any license to entitle a person to practice medicine and surgery in that state, or prescribed any prior test of any kind, nor that the parties suing had taken out any such license or complied with any such requirement. On the part of the county it was insisted that for failure to prove that allegation the verdict rendered for the parties suing could not stand. But the Appellate Court holds otherwise. It says that this question was not raised in any manner in the court below. A plea of tender which was made was an admission of the parties' right to sue for the sum tendered. While it was held in City of Chicago vs. Honey, 10 Ill. App. 535, that in this state an unlicensed physician can not recover fees for his professional services, yet the current of judicial decision in this state appears to be that in a suit for such services a license or due qualification under the law will be presumed. But the laws of Iowa were not proved, and in the absence of proof it is presumed that the common law prevails in a sister state. At common law a surgeon could recover for his services. In Chitty on Contracts, 11th Am. Ed. 836, it is said: "Where there is no restraint imposed by statute, physicians and surgeons in the American states have the same right as others to the benefit of that great principle of the common law that when services are performed on request, and no special agreement is made in reference to them, the law raises an implied promise to pay so much as the person performing them deserves to have, and an action lies on such promise."

# Current Medical Literature.

## AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

### American Medicine, Philadelphia.

*December 19.*

1 *The Finsen Light and Roentgen Rays in the Treatment of Diseases of the Skin. Jay F. Schamberg.
2 *The Diagnosis of Trichiniasis. William F. Cheney.
3 Perforated Gastric and Duodenal Ulcers; with a Report of Four Cases Operated On. John H. Gibbon.
4 *The Influence of the Municipal Milk Supply on the Deaths of Young Children. George W. Goler.
5 *Indications for Operations on the Gall Bladder and Bile Ducts. Randolph Winslow.
6 *The Recent Epidemic of Smallpox in California. Daniel Crosby.

1. **Finsen and X-Ray Therapy.**—Schamberg finishes his paper with the following conclusions:

1. The Finsen light is generally recognized as constituting the best known treatment for lupus vulgaris. It is necessary to employ the large lamp used by Finsen. The smaller modified lamps may suffice for recent and superficial cases, but do not produce sufficient penetration of light to cure long-standing and deep-seated lesions.

2. In lupus erythematosus the Finsen light, in our hands, has effected some improvement but no cures. Cases exhibiting telangiectases and but little thickening of the skin, showed the most improvement.

3. In certain cases of lupus vulgaris the Röntgen rays give most gratifying results. This method of treatment is to be given preference over the Finsen light when the lupus nodules are ulcerated, when the mucous membrane of the nose, lips, or mouth is affected, and probably also in hypertrophic and vegetative forms of the disease.

4. The Röntgen rays have certain distinct limitations in the treatment of cancer of the skin. The rays will cure practically all patients having superficial cancer, and some with carcinoma of the integument. But the majority of deep-seated cutaneous and subcutaneous growths do not do well. They may improve for a while and deceive both the patient and the physician, but relapse, and subsequent spreading is common. Buccal epithelioma and deep-seated epitheliomas involving the lip, had better be treated surgically and subsequently subjected to radiotherapy. The Röntgen rays find a splendid field of usefulness in superficial epithelioma about the eyelids and the nasal alæ, and in rodent ulcers that are surgically inaccessible. Superficial epitheliomas may be cured by many methods, but none gives such beautiful cosmetic results as the Röntgen rays.

5. The Röntgen rays are extremely valuable in acne, in which disease the most brilliant results are obtained, even in long-standing cases.

6. The Röntgen rays are of value in many cases of eczema, both in relieving the itching and in effecting a disappearance of the eruption. The rays have proved of great benefit in recurrent vesicular eczemas of the hands and feet.

7. In psoriasis, the effect of the Röntgen rays is but temporary, and relapses are not less common than under other methods of treatment.

8. The Röntgen rays find a large field of usefulness in dermatologic practice. In addition to the dermatoses mentioned, the rays have been found to be beneficial in sycosis, lichen planus, hypertrichosis, ringworm and favus of hairy regions, tuberculosis of the skin, mycosis fungoides, blastomycetic dermatitis, localized pruritus, etc.

9. In the treatment of diseases of the skin the liability to the production of a burn, with ordinary precautionary measures, is extremely slight.

2. **Trichiniasis.**—Cheney reports a case in which the diagnosis was obscure, most of the findings being negative. There was a general myositis with continued fever, moderate leucocytosis and diazo reaction in the urine. He reviews the prominent features of the case. There was no history of acute onset such as one would expect. A differential count of white corpuscles was made, showing 70 per cent. of polymorphonuclears; 8 per cent. of large lymphocytes; 12 per cent. of small lymphocytes and eosinophiles 10 per cent. There was thus a decided increase in the eosinophiles above normal, though the percentage was not so high as in some of the cases reported by previous observers. The addition of eosinophilia to the previous findings seemed to make the diagnosis positive. Further investigation of the muscle tissues showed trichinæ very clearly present, a fact which can never mean anything else but trichiniasis. Eosinophilia occurs in other conditions, though all these vary so widely from the clinical picture of trichiniasis that practically no difficulty is offered in differential diagnosis. The condition thus becomes one of the most easily diagnosed diseases, provided its peculiar features are borne in mind. The patient did not think she had eaten any pork, and the history was decidedly negative.

4.—See abstract in The Journal, xli, p. 1107.

5. **Biliary Surgery.**—The object of Winslow's paper is stated to be to call attention to the frequency of lesions of the bile passages and the serious effects resulting from their neglect. He would not resort to laparotomy at the onset of every attack of pain in the gall-bladder region, but the existence of repeated paroxysms, persistent or recurring jaundice and a condition of tenderness or distress are serious signs and should not be allowed to continue indefinitely. The difficulty and danger of operation increase in proportion to the length of time, and when a fair trial of internal treatment fails, operative measures should be resorted to without delay.

6. **Smallpox in California.**—Crosby describes the peculiarities of the recent epidemic of smallpox, its mildness, rapidity of evolution and the fact that quite a large proportion of cases responded to successful vaccination after convalescence. Typical pustules and secondary fever were absent, as also pitting and the usual sequelæ. The diagnosis of smallpox, however, is based on the occurrence of some exceptionally severe cases at all points where the epidemic existed, with some fatalities.

### Boston Medical and Surgical Journal.

*December 17.*

7 *Malaria and Mosquitoes of Worcester. A Year's Observations on the Habits of Culex and Anopheles. (To be continued.) William W. McKibben.
8 *Some Cases of Facial Erysipelas from Erosions of the Nasal Septum. John W. Farlow.
9 A Case of Gumma of the Fallopian Tube. George S. Whiteside.
10 *The Indol of the Feces as a Measure of Putrefactive Processes in the Intestines. A. E. Austin.
11 *Was He Insane? A Study in Mental Diagnosis. (Concluded.) C. A. Drew.

7. **Malaria.**—McKibben gives the history of the introduction of malaria into Worcester by Italian laborers and returned soldiers, and of the epidemic that occurred there.

8. **Erysipelas.**—Farlow calls attention to a probably overlooked cause of so-called idiopathic empyema, namely, erosion of the nasal septum, and reports cases where this probably existed. The treatment of the nose seemed to be an important factor in the suppression of the attacks.

10. **Intestinal Putrefaction.**—Austin has investigated the indol contents of feces as an index of intestinal putrefaction. He remarks that the amount of indol found is vastly greater than that found by Baumstark, who regarded 17 mgms. as the

average normal quantity, and the largest amount he discovered in pathologic conditions was 114 mgms. The analysis of Austin, however, ranged from 22 to 260 mgms. He thinks it is possible that the larger amount was due to the fact that skatol was reckoned with it. As to the purity there can be no question, both from the methods by which they were obtained, excluding all other products, their well-defined crystalline form and the response of indol to Legal's reaction.

11. **Querulant Insanity (?).**—Drew finishes an interesting account of a case of moral depravity and suspected moral insanity which, he concludes, was not properly insanity. The condition, he thinks, hardly comes within the legal conception of insanity.

### Medical Record, New York.

*December 19.*

12 *Leprosy in Hawaii. James T. Wayson.
13 *The Diagnosis and Treatment of Intussusception, with a Report of Four Cases. Henry Roth.
14 *An Unappreciated Source of Typhoid Infection. P. B. Barringer.
15 *Points to Be Observed by the Family of a Tuberculous Patient. C. P. Ambler.

12. **Leprosy in Hawaii.**—According to Wayson leprosy was not introduced into Hawaii by Chinese, but probably came from the South Sea Islands some time before. He thinks that a markedly syphilized race is especially likely to lepra infection, probably carried by spores not yet found. He describes the Molokai asylum, and suggests the probability of its having to be made a national asylum, and refutes the objections made to this course.

13. **Intussusception.**—Beside reporting cases, Roth discusses the literature at considerable length. He believes that intussusception in children may and should be diagnosed early. The characteristic symptoms are marked, and if the disease is borne in mind it is almost impossible to fail to recognize it. He believes in operation as the only practical treatment. Injection and inflation are unscientific and dangerous. If the case is seen early enough and reduction by mechanical means attempted, all preparations should be made for an aseptic and rapid laparotomy. Attempt at reduction by pulling on the bowel is very dangerous; it is best done by pressing on the apex of the intussusception through the ensheathing gut. In early cases reduction will readily be accomplished. In desperate or gangrenous cases resection may be required, with entero-anastomosis or an artificial anus, leaving the intussusception unrelieved to take care of itself. Entero-anastomosis has not the advantages of complete or partial resection.

14. **Typhoid Infection.**—The danger to the traveling public from the common arrangements on the cars, where infected feces are dropped along the railroad tracks to be scattered in the form of dust, is especially noted by Barringer. He found that in railroad hospitals a great majority of the typhoid cases are track men, who are not exposed to the dangers of water-borne infection. The people who work along the track are not the only ones liable to danger. Those traveling on the train, especially on the rear cars, also suffer serious risks of infection. The remedy, he thinks, lies in retention closets which can be cleaned at the end of the trips.

15. **Tuberculosis.**—Ambler enumerates the precautions which the tuberculous patient should observe to avoid danger to others, namely, proper deposit of expectoration, thorough cleansing by boiling in water all the eating and drinking utensils used by him, the avoidance of kissing and coughing as far as possible. Tuberculous patients should not be employed in markets where foodstuffs are sold, and should not handle or prepare food for the family. The room occupied by them should be so arranged that the dust floating in the air can be kept at a minimum, without carpets or rugs, and well ventilated. Wounds and abrasions should be looked after, and small children crawling on the carpets should be especially cared for. The patient should avoid public halls and meeting places.

### New York Medical Journal.

*December 19.*

16 *On the Etiology of Pulmonary Tuberculosis in Its Relation to Diseases of the Nose and Throat. W. Freudenthal.
17 *Remarks on Mechanotherapy, Massage, Bone Setting and Osteopathy. John Madison Taylor.
18 *On the Natural Habitat of the Tubercle Bacillus. J. W. Kime.
19 *A Method of Rapid Extirpation of Nasopharyngeal Fibromata, with Report of Cases. Gordon King.
20 *Things Every Tuberculous Patient Should Know. Martin L. Stevens.
21 *The Genesis and Nature of Medicinal Dioxides. Friederich Elias.

16. **Tuberculosis.**—The importance of the conditions of the nasal passages in the etiology of tuberculosis is pointed out by Freudenthal, who refers to a former article. He especially considers that atrophic rhinitis through the too free passage of air through the nasal channels causes a lodgment of the tubercle bacilli in the back of the pharynx, where they have an excellent chance to develop and introduce themselves into the system. A rhinitis sicca, or even more atrophic rhinitis, unfits the nose entirely for respiration. Adenoids also favor the lodging of bacilli in the pharynx and their passage thence into the lymph current. He thinks that glandular swellings of the neck have become less frequent since adenoids have been so freely removed. If the path of the tubercle bacillus downward is closed up by adenoids, it may make its way to the cranial cavity and produce tuberculous meningitis. He tabulates a number of cases of consumption with particular attention not only to the condition of the nose, but also of the teeth, with special reference to the dry and atrophic conditions produced by our methods of heating in this climate. If we want to treat the consumptive rationally, he concludes, we must begin at the upper air tract.

17. **Mechanotherapy.**—Taylor points out the importance of massage, mechanotherapy, bone setting, etc., and the practice of osteopathy. He thinks the profession has become too critical in regard to drugs, and the public has followed its example, and takes up the more readily with charlatans, who claim to cure without them. Moreover, there are comparatively few of the medical profession who have familiarized themselves with massage and mechanotherapy generally. Our schools of massage are entirely superficial in their training. The European masseur finds our physicians unable to appreciate his skill, hence his attempt to get into independent practice, and the prejudice and rivalry aroused against him. Taylor claims that the field of mechanotherapy is boundless, and it is the duty of the educated physician to learn more of it. He thinks if the medical profession would read half a score of small books thoroughly (after revising their knowledge of the nervous mechanisms) and make practical use of the light thus gained, they would feel little hesitation in going forward to acquire skill in so practical and valuable a branch of therapeutics. The physician can not devote the time required by some of the more laborious and continuous, or routine procedures, but he should supervise the scientific part. He could and should make use of the more delicate manipulations, which are of the greatest value. To illustrate the teachings of the osteopathic schools, he mentions two graduates of Scandinavian massage institutions who came to this country and hearing of osteopathy took a course at Kirksville. Both assured the author that they learned no facts of importance not already known to them. The sphere of manual therapy lies in the ability of medical practitioners to influence centers of organic activity by mechanical stimulation through the vasomotor nerves. They should not abandon well-tried and proven remedies, but in manual therapy, when applied by the physician, there is a prompt and exact method far in advance of all others in the treatment of a wide variety of derangements, not only of the coarser mechanisms, but also of the vital organs.

18. **The Tubercle Bacillus.**—Kime reviews the habitat of various pathogenic parasites, and claims that the natural habitat of the tubercle bacillus is in the cow. He says the conclusion forces itself on us, even from Koch's own experiments, that the cow furnishes the type of soil and tissue best adapted to the production of virulent tubercle bacilli, and the more immediate the transference of tuberculosis from cow to man, the more deadly it becomes, and the more readily it may be transferred back, while cultures many generations removed

from the cow lose much of their virulence, and are comparatively mild in their effects.

19. Nasopharyngeal Fibromata.—The method of treatment of these growths is discussed in general, and King describes a method which he thinks is more quick and effective than others. He makes a high tracheotomy under chloroform anesthesia and inserts a tube. Then with the patient in the Rose position, the head supported by an assistant, and the mouth gag in place, the index and little [middle?] finger of the left hand are introduced into the nasopharynx to ascertain carefully the outlines of the tumor and the position and extent of its implantation. This is of great importance, for as soon as the size and point of origin of the pedicle are made out, the fingers serve as a guide for the insertion of a pair of scissors into the nose on the side most accessible to the pedicle. Scissors are a strong pair, with long handles and short blunt blades, slightly curved on the flat. The long handles offer a strong leverage, so that the toughest tissue can be cut through. The closed blades are introduced carefully along the septum until the point can be felt in the nasopharynx. The instrument is guided by the fingers to the pedicle. With the convexity of the blade uppermost the pedicle is vigorously attacked and divided. As soon as it is felt detached, it can be drawn out by the fingers through the mouth and immediate attention given to checking the flow of blood which gushes copiously from the moment the first cut is made. The use of a gauze pack aided by the natural tendency to spontaneous arrest will check the bleeding in a very short time. The head can then be brought to a level with the table, and if it is made certain that none of the body of the growth remains behind, the tracheal tube can be removed and the wound closed. In this manner the bulk of the growth at least can be removed. If hemorrhage has been excessive the patient should be allowed a few days to recuperate before being subjected to further operation for the complete removal of what may remain behind. Not much time, however, should be lost in attacking the root of the tumor. It should be examined closely by anterior and posterior rhinoscopy. Remaining fragments can be removed under light with snare, cutting forceps or scissors, or destroyed by the use of cautery without further danger of serious hemorrhage. In view of the tendency to recurrence great care should be taken to extirpate as completely as possible and the patient kept under observation for several weeks for new developments. He reports three cases, with details, in which this operation was performed.

20. What the Tuberculous Patient Should Know.—Stevens insists on the tuberculous patient coughing into a handkerchief, not coughing at all in the dining-room, never swallowing the expectoration, using an antiseptic mouth wash before each meal, and the careful cleansing of the hands, avoiding talking if it increases the cough, avoiding spitting into anything excepting a proper sputum receptacle, the thorough disinfection of whatever is soiled by the sputum, abstinence from kissing, taking exercise only under direction and none of a sporting character, taking none if the temperature is abnormal, if there is blood in the sputum or if losing in weight. Always stop before becoming tired, never run or get out of breath and never lift or strain, avoid breathing exercises except those as specifically directed. If the temperature reaches 100 lie down, and if it reaches 101 undress and go to bed in earnest. Spend ten hours in bed each night, and retire early enough to finish your sleep before sunrise. Spend all the time possible in the open air. Keep the windows of the sleeping room open. Protect the head from the direct rays of the sun when taking outdoor rest cure, avoid dust, draughts, crowded and poorly ventilated rooms, and if you catch cold report at once to the physician. If the digestion is good, use a generous mixed diet, taking no food between meals. Forced feeding, if necessary, must be under the direction of a physician. It is not the quantity eaten, but the quantity digested or assimilated that benefits. If not on a full diet, a light luncheon of milk and crackers, malted milk or raw egg should be taken regularly two or three hours after each meal, taking no food within less than two hours of a regular meal. Do not drink milk hastily. Sip it, eating something at the same time. Regularity of meals is essential. Take only such medicines as are prescribed and stop any that disturb the stomach; beware of sleep producers. Throw away any medicines that have been ordered discontinued. The clothing should be adapted to the individual; avoid chilling and overheating; wear nothing that interferes with respiration. Use sensible footwear, and no chest protectors. Unless there is special reason for not doing it, a cold sponge bath or shower bath should be taken each morning, and a full warm bath only once a week, rubbing the skin well with a course towel after the shower or sponge bath. Omit the cold baths during a pleurisy, or after a night sweat, or if the morning temperature is below 97 F., using a dry rub instead. Alcohol, if prescribed in exceptional cases, should be used the same as medicine and with the same care as to dose and time as with other medicines. Smoking should not be indulged in, and chewing should be condemned for sanitary reasons, because it increases the tendency to expectoration. Co-operate with the medical advisor, make a business of getting well. Do not take too many suggestions from outsiders. The less one knows of a subject the more ready he is to advise. Avoid self-experimentation. Do not discuss your symptoms with other patients. If you do not trust your physician, change him.

21. Magnesium Dioxid.—This substance, which is also known as biogen, and zinc oxid, known as dermogen, seems to have a special power of giving out oxygen, and Elias discusses their action. He thinks the pronounced benefit resulting from magnesium dioxid is entirely due to its oxygen quality, and not to its residual magnesium hydroxid. The increased heart action, the rapid elimination of waste products, accelerated tissue oxidation and destruction of pathogenic micro-organisms, all point to the conclusion that it is the oxygen to which these results must be attributed, and not to the magnesium. The latter is an indifferent substance, almost entirely recoverable in the excreta. The utility of magnesium dioxid when introduced into the system, he says, is evidenced by the marked improvement and rapid subjective symptoms induced. This is explained by the fact that an oxygen carrier such as magnesium dioxid breaks down when administered internally and liberates a more active and less irritating gas than oxygen which may be generated by other means.

29 Cases Simulating Appendicitis. H. A. Brennecke.
30 Pulmonary Tuberculosis and Its Home Treatment. James L. Lowrie.
31 A Report of Three Medicolegal Cases Involving the Diagnosis of Paranoia. Sanger Brown.

26. Chorea.—Mettler concludes that chorea is not a disease, but only one of a group of symptoms which may be due to various etiologic and pathologic conditions. It is traceable to some irritative factor in all its varied manifestations. The difference between the various choreas depends not so much on the choreic movements as on the associated symptoms of the trouble or disease in which the choreiform phenomena form one symptom. He thinks this is logically proven and demonstrable when one observes carefully the etiology, symptoms, prognosis and treatment of every case. He adds that this is the only way to look on chorea in order

to comprehend it thoroughly, to be able to make a correct diagnosis and apply the best line of treatment.

27. **Ovarian Dysmenorrhea.**—The new operation here described by Kerr consists, after the usual preliminaries of laparotomy, in holding the uterus and ovary forward on the side operated on, and then slitting the peritoneum covering the ovarian vessels, viz., the infundibulo-pelvic ligament parallel to the vessels. The areolar tissue is then stripped from the under surface of the peritoneum so as to include, if possible, any nerve fibers that may be present in this space between the two layers of the fold of the peritoneum above mentioned. After this a ligature is applied at the brim of the pelvis to the ovarian vessels. It also includes the loose tissues which have been stripped from the extraperitoneal surface of the peritoneum. After ligation is completed at this point, the same process is repeated an inch or more further down on the vessel and areolar tissue quite near the outer end of the ovary, after which the part between the ligatures is excised. It is necessary, of course, to repeat the same process on the other side of the pelvis because in these cases the neurotic element is very pronounced and the pain is usually referred to both ovarian regions. He reports cases and gives credit for the suggestion of the operation to Dr. M. L. Harris.

37 The Prevention of Perineal Lacerations. Edward N. Ewer.
38 Infectious Pulmonary Edema. Preliminary Report. W. Ophuls.

32. **Kidney Decapsulation.**—In Goodfellow's opinion decapsulation of the kidney for chronic Bright's disease is a perfectly justifiable operation, particularly with patients *in extremis*, and is a safe procedure. Spinal anesthesia is of great value in these cases where general anesthesia can not be given. He reports a case and reviews the experience of others on the subject.

35. **Tuberculosis in Fowls.**—This disease exists rather extensively in large chicken farms, but has not been specially noted on account of the fact that the proprietors count on a certain amount of loss, and have not given their attention particularly to this form of disease. Ward gives the results of his findings, with illustrations. The symptoms are only noticeable in advanced cases; the bird becomes anemic and weakened, the lesions are most frequently shown in the liver and spleen, only rarely in the lungs. Out of thirty postmortems, in only one instance were the lungs involved, and the skin in another. He does not think that it is dangerous as regards infection by ingestion, as the thorough cooking to which poultry is subjected renders the possibility rather remote. It would be of interest to find out whether the eggs are affected; as a rule, tuberculous hens do not lay eggs. The tuberculin test seems to be unavailing in these birds. He believes that the weeding out of tuberculous hens would in a few years eradicate the disease, their short life being favorable for this. It is possible that the weeding out of all chickens that have pale combs and are poor, keeping them separate from the others, would be of great value in this connection.

45 The Development of the Islands of Langerhans in the Human Embryo. Richard M. Pearce.

39. **Facial Palsy.**—Frazier first reports a case in which after gunshot wound there was complete facial palsy irreparable except by operation. An anastomosis was made of the peripheral end of the facial nerve with the central portion of the hypoglossal. He discusses the different possibilities of anastomosis with the spinal accessory, hypoglossal and glossopharyngeal, the latter being not especially suitable. He remarks that the operation is not exceedingly difficult, but the nerve should be manipulated with extreme delicacy and there should be a minimal number of sutures, all in perfect apposition and aseptic. He recognizes three stages of improvement: 1, The restoration of normal muscle tone which would warrant the operation; 2, the voluntary control over individual muscles, and, 3, complete and perfect recovery, that is, the return of expressional movements, etc. The first can be ordinarily expected, the second is liable to follow. The latter would be more likely the younger the patient.

Spiller discusses the subject from the neurologist's point of view, and thinks that operation affords a bright prospect for the relief of the deformity and facial paralysis, though experience is needed before we can justly estimate its advantages.

41. **Morphin.**—The conclusions of this experimental research by Reichert are that morphin coincidently possesses thermodepressor and thermoaugmentor actions, the former being by far the more important; and that the thermodepressor effects may be preceded or interrupted by thermoaugmentor effects. That the thermodepressor action is exerted, practically solely on the caudate thermoaugmentor center. That the thermoaugmentor action is exerted chiefly on the pontobulbar thermoaugmentor center, and to a very limited extent on the skeletal muscles. That morphin and cocain are direct antagonists in their actions on the caudate center.

46 *The Present Status of Phototherapy. Frank Hugh Montgomery.
47 A Case of Undetermined Infection of the Skin: Possibly Glanders. J. A. Fordyce and A. D. Mewborn.

46. **Phototherapy.**—Montgomery's article is a very complete statement of the present status of light treatment, and he describes the apparatus and technic, reviewing the results. The idea that the light treatment can be utilized for deep-seated affections receives but little support from his study of the subject, but for superficial disease it is unquestionably of great value. Of all known methods, he says, of treating lupus vulgaris and other forms of cutaneous tuberculosis, phototherapy is the most certain in its action and gives the best cosmetic results. Where the skin is badly pigmented or there are mechanical obstacles such as peculiar or irregular scars, densely infiltrated or hypertrophied areas, or where the disease is so situated, as is usually the case, on a mucous membrane as to be inaccessiblle to pressure and direct radiation, the *x*-rays are the most effective.

48 *A Few Remarks Concerning the Surgery of the Biliary Passages. Maurice H. Richardson.
49 *Suggestions on the Nature and Treatment of Delirium Tremens. James F. Kelly.
50 Avoidable Causes of Mortality in Tuberculosis in the Southwest. Guy H. Fitzgerald.

48. **Surgery of the Biliary Passages.**—Richardson notices a number of interesting points in regard to gallstone surgery, especially the hardened, almost cartilaginous, condition of the pancreas sometimes observed, the frequent association of abdominal pain with old and extensive adhesions, and the obscure symptoms caused by lesions of the other viscera in the right upper quadrant of the abdomen, such as those following pyloric disease, etc. Sometimes where gallstones are indicated other and quite different conditions are found. He mentions, for instance, a case of pyelonephritis which had never been suspected, another of intermittent hydronephritis, others of kinks and flexures of the pylorus and duodenum. He believes that surgery of the gall bladder will be immensely advanced in the near future, though there are yet many

questions still in suspense, such as when to extirpate the bladder and when not and when to drain the discharge. He has made systematic observations in the course of abdominal operations wherever conditions permitted. He has frequently found gallstones where there were no symptoms. In some cases the gall bladder has been packed with stones. He can also recall cases where failure to examine the right upper quadrant of the abdomen has resulted in operations lower down in overlooking highly important matters. He thinks where the appendix is removed through an one-inch incision it is poor surgery to enlarge the cut, as a rule, for so uncertain an addition to our knowledge of the case. He holds that gallstones are never dissolved or removed by any course of medication, but may remain latent only to be aroused under very unfavorable conditions. He also holds that cholelithiasis is permanently cured by drainage of the gall bladder. Gallstones almost always originate in the gall bladder, though they may be found in the hepatic duct, and sometimes up in the great fissure of the liver. The liability to overlook them by even the most experienced is very great. The most interesting subject connected with the biliary tract is that of the pancreas. He formerly was inclined to look with disfavor on any case of supposed gallstone associated with enlargement of the head of this organ, but has seen instances where his unfavorable prognosis was belied by his experience. Biliary drainage of the gall bladder for pancreatic congestion seems to be beneficial. Clinical observation shows its value, and the cases are multiplying. He thinks it is not too much to hope that through early recognition of impending disaster acute infection of the pancreas with hemorrhage and fat necrosis can be anticipated and avoided by so simple a procedure as temporary drainage of the biliary tract. Looking back on the results at the Massachusetts General Hospital for the last fifteen years, he is impressed with the evils of so-called conservatism in this line of surgery.

49. **Delirium Tremens.**—Kelly's article is noticed editorially.

56 Presentation of a Patient, the Subject of Calculous Formations in the Kidney, Ureter and Bladder. Bransford Lewis.

51. **Fat and Nervous Disease.**—Loveland makes the points that the depositing of fat in the body is under the functional control of the nervous system, and that a careful study of the patient with regard to the question of fat may be of value both in the diagnosis and prognosis. The physician may soon so learn his patient that he can prescribe a diet and tell with reasonable certainty whether he will lose, keep the same, or gain flesh. Lastly, that an increase in flesh may be taken as an index of improvement in acute mania, melancholia and in thin neurasthenics, as well as in tuberculous patients where it has long been recognized as such.

58 *Studies on the Cerebral Cortex in the Normal Human Brain and in Dementia Paralytica. G. Alfred Lawrence.

58. **Dementia Paralytica.**—Lawrence concludes his article in this issue, reviewing the technic and discussing the results. He finds that the thickness of the various cortical layers is not constant in the same gyrus or even in the different portions of a single section, to say nothing of different cortical regions. From his study of the literature, as well as his own investigations, he is inclined to accept the view of the three-layered type of cell arrangement, excepting, of course, variations in special parts, such as the cornu ammonis for example. The first or superficial layer contains few nerve cells, many neuroglia cells and many, chiefly tangential, fibers. The second, or pyramidal cell layer, includes small, large and giant cells, and the third, or spindle cell layer, includes both the spindle cells and the less numerous irregular polygonal cells. Below these three layers is the subcortical white medullary substance. He finds four principal types of nerve cells: 1. The small rounded nerve cells with few dendritic processes, with rounded nucleus almost filling the body and well-marked nucleolus, so-called karyochrome nerve cells of Nissl's classification. 2. The pyramidal cells of the second layer, of which there are four varieties: small, large, medium and the typical giant pyramidal cells. These can best be designated as stichochrome nerve cells of the somatochrome class in Nissl's classification. 3. The spindle cells found in the third layer contain a very large nucleus with well-marked nucleolus. These are the gryochrome nerve cells of the somatochrome class. 4. The irregular or polygonal nerve cells found in the second and third layers, irregular in shape, with three or more dendritic processes, a large nucleus and well-marked nucleolus. The pathologic changes in dementia paralytica noted by previous observers were all observed by the author excepting vacuolization of the cell protoplasm and pigmentary deposits outside the nerve cell bodies. No vacuolization of the nucleus or extrusion of the same was found and no crystalline or calcareous deposits were made out in any of the cells; no septa were observed penetrating from the thickened pia into the cortex. Multiplication of white corpuscles was not observed, and proliferation of neuroglia cells seems to have existed but to a slight extent in small localized places. He does not mean to say that it may not occur in some cases and be more general. No proliferation of the interstitial network was noted. The pathologic processes were more severe in the central and frontal regions, but extended to a less extent, though still marked, into the temporal and parietal region, the occipital region almost entirely escaping in the case observed. The disease seemed to be a chronic affection of the nerve cells with pigmentary degeneration, necrosis of the cell body, partial or complete, with accompanying involvement of the blood vessels. The relation of the vascular and cell changes to one another and their relation in time is a subject that he thinks requires much more extended investigation before it can be satisfactorily settled.

64 Poisoning Due to the Chemical Decomposition of Bromoform. A. L. Oberdorfer.

59. **Summer Diarrhea of Children.**—The discussion here published was opened by Flexner, who gave the facts in regard to the identification of the bacillus found in summer diarrhea of children with the Shiga bacillus, and pointed out in what cases they were likely to be found. He mentioned also that there were two well-defined groups of organisms of the dysentery bacillus, one producing a change in the litmus and one not. One was found that agreed with the ordinary Shiga bacillus, but he thinks more care must be taken in the study of the subject. The future must determine what position the organism occupies with reference to the etiology of summer diarrhea.

Park gave his experience with a dysentery epidemic near New York City in which this Shiga bacillus was found. He thinks it does not occur in the larger proportion of cases of summer diarrhea, and he would expect mucus and blood in most instances where it is found.

Koplik pointed out the complexity of the question. He is inclined to think the Shiga group is a limited class. The larger number of cases are due to other germs such as the butyric acid bacillus and the *Bacillus lactis aerogenes*. Still others are due to the anatomic and physiologic insufficiencies of the intestine to tolerate the irritation from cow's milk, a food not exactly adapted to it. Holt stated that a search for the Shiga bacillus in the Babies' Hospital revealed it in 37 cases out of 112 examined, all of these with symptoms of colitis, mostly acute, with mucus and often bloody stools. The Flexner anti-dysentery serum was used in 8 cases. Two were moribund; in 3 no effect was seen, but in 3 others very striking improvement was apparent.

Knox gave the results of observations at the Wilson Sanitarium in Baltimore and remarked that there was nothing in the character of the stools or pathologic condition at autopsy to differentiate the cases with the Shiga bacillus from the ordinary typical summer diarrhea. He thinks it is quite possible that a large group of both acute and chronic cases will be found due to this organism.

Dr. Booker of Baltimore examined only one case last summer for the Shiga bacillus. It belonged more to the cholera infantum type than to dysentery. Two injections of Flexner's serum did not check the disease, though a slight improvement was noticed after the first. He thinks if we get results from the serum treatment it will be when used in the early stage of the disease before serious anatomic changes have occurred. It has been suggested that the rôle of the Shiga bacillus is to render the intestine more suitable for the activity of other bacteria. If this prove true, the greater the advisability of the early use of the serum.

In closing the discussion Flexner remarked that he agreed with the gentlemen who had spoken of the complexity of the problem, and emphasized that he had not committed himself to any view of the causes of summer diarrheas excepting that this organism occurred in some of them. He is convinced that whatever the Shiga bacillus does it does early, and we have to deal with mixed infections. How much of this complex mixture is a condition of an early infection is an important question. The serum is, of course, experimental. As tested on animals it is very effective and is at least, he thinks, worthy of a trial.

60. **Pneumothorax in Children.**—Five cases of this rare condition are reported by Bovaird. In 2 it was produced by rupture of areas of bronchopneumonic consolidation occurring as complications of measles; in 2 by rupture of a small abscess of the lung, the clinical history of which is not known, and a fifth case which was probably due to a rupture of an emphysematous vesicle. As the latter case was only partial and the patient recovered, the etiology could not be exactly determined. He reviews the literature and remarks that as only 4 recovered out of the 18 cases collected, pneumothorax in children must be considered a very grave complication. With our limited experience we can not lay down a treatment, but the extensive displacement and consequent interference with the function of the heart suggest the advisability of withdrawing air from the pleura, or in the event of failure in this, to make a free incision.

61. **Chorea.**—Aldrich reviews the different forms of chorea, limiting the term properly to the Sydenham type. He describes its course, symptoms, diagnosis, etc. Owing to the absence of characteristic lesions the belief is growing, he says, that the disease is due to irritation of the motor mechanism in the cells of the cerebral cortex by some infectious irritant. Individual predisposition plays a part, and it must be regarded as a disease of neurotic stock, unable to meet the strains of early school life, to withstand the changes of adolescence as well as early pregnancy, in fact, unable to meet anything that lowers the normal physiologic resistance. The cases attributed to fright almost always show on analysis that this is only a climax in the course of a disease already established. Peripheral and reflex irritation, as from worms, eyestrain and adherent prepuce, play no part in the etiology of true chorea any more than poor hearing or ingrowing toe nails.

73 A Case of Acute Otitis Media and Sinus Thrombosis; Mastoidectomy; Excision of Internal Jugular Vein; Serous Meningitis; Exploratory Craniotomy; Death; Autopsy. Edward B. Dench.

65. **Suppurations of Accessory Cavities.**—In the beginning of his article Luc declares his agreement with Lermoyez in his statement that surgical treatment ought to be limited to chronic forms of the disease. In these chronic forms we should distinguish between the properly called suppurative sinusitis, due to primitive infection, and the maxillary empyema in which the pus does not originate in the cavity but simply accumulates in it. In the latter, a simple washing of the cavity may sufficiently relieve the conditions. Luc does not consider it advisable to adopt the radical operation in chronic abscess of the antrum without previously having attempted to cure it by washings if a puncture has been made in the inferior meatus. As regards the Luc-Caldwell operation he admits Caldwell's priority, while claiming independence in the origin of the method. He mentions the Ogston-Luc method for frontal abscess pointing out certain defects in unfavorable cases due to the excessive size of the sinus as compared with the outlet provided, and mentions with approval the Killian operation for these cases. He has no personal experience with an isolated ethmoidal suppuration, and consequently has treated it usually in connection with frontal and maxillary disorders. The ethmoidal labyrinth is attacked by him by a new method, which dispenses with the socalled nasal curette and substitutes a special forceps. He describes the methods of using it, first attacking the middle turbinate to make way for the opening of the ethmoidal cells. The choice of the route to the sphenoidal cavity is according to the spaciousness or narrowness of the nasal fossæ and the coincidence or non-coincidence of an empyema in the maxillary antrum, the latter being the safest and easiest way to the sinus. When there is nothing more than the middle turbinate and the posterior ethmoidal cells in the way the method used in intranasal curetting of the ethmoidal cells can be employed with advantage. Only when there is an abnormal resistance of the anterior wall of the cavity is it advisable to have recourse to a perforator and enlarge the opening thus made by a cutting forceps. The coincidence of an antral empyema with the sphenoidal suppuration settles the question as to the mode of reaching the sphenoidal cavity. The antral route is the best in such cases.

66. **Nasal Sinusitis.**—Freeman insists on the use of all methods of examination and notes the embarrassment frequently caused by failure of the transillumination tests. The presence of polypi and edema of the mucosa in the neighborhood of the sinus ostium should call our attention to the nasal sinus. No sign has been as useful to him as the discovery of pus flowing over the upper surface of the posterior end of the inferior turbinate. He has frequently been able to make a diagnosis by odors, such as those of sour pus and of sulphuretted hydrogen. The continued presence of foul odor of the antrum secretion almost unerringly points to the teeth as the cause of inflammation and the presence of discolored molars or bicuspids should be viewed with suspicion, and the tests of heat and cold and transillumination be applied. In washing the antrum through the normal opening he has found it of use to explore first with a delicate cotton-wound probe, and after the opening has been detected and the correct curve attained, to fashion the curve of the canula after it. He has devised a special irrigation canula which by heating can be fashioned to any curve and will often bend and conform to the irregularities. He has found it more convenient than the metal tube, and very serviceable in every way. As regards ethmoidal disease

from grippe he has never seen any case of this origin which did not recover in a few weeks. He does not believe that chronic suppurations of the ethmoidal cells exist to the extent that certain statistics would indicate. He warns against turbinectomy, and thinks that before thorough investigation, before sacrificing the middle turbinate it is due to the patient to suspect the antrum and try irrigation. Ethmoidal suppuration is frequently diagnosed and antrum disease overlooked. Lichtwitz' statistics are quoted in this connection. He thinks attention is being directed too much to the ethmoids and the antrum too much disregarded. The assertion of Schaffer and others that the formation of crusts in the pharyngeal vault suggests sphenoidal disease is, he thinks, misleading. Vertigo and pain at the occiput, deep in the eyes and in the ears, may be caused by disease of any one of the sinuses and pain across the bridge of the nose, considered so characteristic of ethmoid disease, he has repeatedly caused by manipulations in the sphenoid cavity. The close proximity of the fifth nerve makes reflex pain at any part of the head possible. He has had cases where the frontal or the antrum were positively the only cavities involved, in which there was intense earache sometimes of the corresponding side and sometimes of both. Any great reliance on the symptom of pain, therefore, is liable to be misleading. As regards ocular manifestations, he quotes Posey, who says that general symptoms of asthenopia, not relieved by glasses, should direct attention to the nasal sinuses. When drainage is abundant and the turbinate swollen, positive diagnosis of the special cavity is impossible, but by contraction by cocain and repeated cleansing by anterior and posterior syringing one can usually arrive at a fairly accurate diagnosis by watching the pus appear at its special locations. The washing should be done so that the water is caught in a black basin. The use of suprarenal extract is not advisable in sinus suppurations as the blanching of the surface prevents the recognition of small amounts of secretion. A point he has found of value in carrying out the Fränkel and other position tests is to have the patient close the opposite nostril and sniff and blow alternately. This draws the pus from the sinus. Where there is difficulty in detecting the cavity the patients should be examined early in the morning before the sinus has emptied, and late in the evening when the sinus has had a chance to refill. The morning is favorable for detecting pus from the frontal and ethmoids, the evening for secretion from the antrum and sphenoid.

67. **Sphenoidal Cell Disease.**—Myles holds that the sphenoidal cells are more often diseased than we have believed. When muco-pus is seen in the superior meatus or between the middle turbinate and the septum, the probe and cleansing swab should be used until the secretion is traced to its origin. Sometimes the posterior half of the middle turbinate will have to be removed to investigate the region, and he thinks we are often too conservative in not removing the body early and more frequently. When a diagnosis has been made and the character of the case approximately determined, we should endeavor to make an opening 10 to 15 mm. in diameter in the anterior superior wall, commencing the section at the lower border of the natural opening and extending downward in a vertical line, rather close to the septum. He illustrates the instruments for this purpose, all made with guards, and reports cases.

74. **A New Advancement Operation.**—Savage's claim for his operation is that it is done without cutting the tendon. He also describes a special method of taking scleral stitches. He makes: 1, a cut through the conjunctiva parallel with the plane of the equator, a short distance behind the tendon insertion, not including the capsule of Tenon. 2. An opening through the Tenon capsule just below the border of the tendon, through which he passes a large strabismus hook, beneath the tendon. When the point of the hook reaches the structures above the tendon a snip should be made in the capsule so as to allow it to emerge. 3. The tendon is lifted by the hook so as to make the taking of the stitch through the muscle and capsule easy, without dipping the needle into scleral structure. The stitch is done as in plain sewing and the puncture and counter-puncture should be one-eighth to three-sixteenths of an inch apart, the conjunctiva being held back with forceps by an assistant. The loop, consisting of the middle of the suture which is armed with two needles, is beneath the central part of the muscle at just that distance behind the tendonous insertion indicated by the operator's judgment. 4. The forceps and hook having been removed, the operator taking the fixation forceps in his own hand, seizes the tendon at its insertion so as to hold the eye steady while passing two needles into the scleral tissue, the anterior conjunctival flap being held forward by an assistant. Either needle may be passed first. The points of passage are chosen with the view of not changing the plane of action of the muscle if there is no cyclophoria, or of changing it if there is. In the former case one needle is passed just as far below the plane of the horizontal meridian as the other is to be passed above this plane. The lower needle should be held parallel with the plane of the equator and well behind the canal of Schlemm. The puncture made below and the counter-puncture made above should include only a narrow band of scleral fibers and the dip of the needle into the sclera should not be too deep. A similar vertical stitch above the horizontal plane should be taken with the other needle. The space between the two vertical stitches should be as broad as the stitch previously taken in the muscle, and the one scleral stitch should be as far below the horizontal plane as the other is above. After the scleral stitches the two needles should be passed through the anterior conjunctival flap. Lastly, he ties the suture over the silver suture plate devised by Dr. G. H. Price of Nashville. The two needles having been passed through the two holes in the suture plate are now removed and the surgeon's knot is tied, but not until that part of the muscle through which the loop was passed has been drawn as far forward as necessary, usually up to the scleral stitches. He says since this part of the muscle can not be drawn a greater distance in advance of the tendon insertion than the distance between the loop of the suture and the tendon inserton, it becomes evident that the muscle stitch should be the same distance behind the insertion of the tendon as the scleral stitches are in front of it. The folded muscle and tendon lie flat and the posterior conjunctival flap is drawn forward nicely. He has not seen this operation described elsewhere.

87 *Peritoneal Adhesions in the Pelvis. Henry C. Keenan.

84. **Uterine Carcinoma.**—Hopkins pleads for the treatment of uterine carcinoma by the combined use of the Finsen light and the Röntgen ray; one hour exposure of the former and five or eight minutes of the latter is a good proportion. This has given him excellent results without causing any injury. He

describes his technic, using the ordinary bi-valve speculum if the vagina is not involved, protecting the lateral walls with tinfoil. While most of his cases have been pretty far advanced the results have been such as to encourage him with this treatment.

87. Peritoneal Adhesions.—In pelvic peritoneal adhesions Keenan would advise laparotomy in pus cases, but in cases of post-operative adhesions a thorough course of medical treatment, including massage, should be given before asking the patient to submit to the uncertain results of a second operation. He thinks we need more detailed information as to the remote results in these cases so as to form a better idea of the course of treatment.

1. **The Prolongation of Life.**—The advice of Weber for the prolongation of life is summed up in moderation in eating, drinking and physical indulgence, securing of pure air out of doors and in, keeping of every organ of the body as near as possible in constant working order, daily regular exercise in all weathers, supplemented in many cases by breathing exercises, climbing and walking tours, early going to bed and rising and restricting of sleep to six or seven hours, daily baths according to individual conditions, cold or warm, or warm followed by cold, regular work and mental occupation, cheerfulness, employment of the great power of the mind in controlling passions and nervous fears and strengthening the will in carrying out whatever is useful and checking the craving for stimulants, alcoholics and other injurious agencies.

2. **Pneumonia.**—Lees' third lecture describes the physical examination and treatment. As soon as the condition is recognized he would put hot water bottles to the feet, ice bags over the suspected part of the lungs, use cleansing of the mouth and fauces and spraying the throat every three hours for the first two days. Infection often starts from the mouth. The diet should be milk, or milk and barley water, given every two hours, and water as desired. The patient should be seen a second time the same day and any increase of dullness be treated by local application of ice. This may arrest the disease. The temperature will then be lower the second day and the air will enter the suspected area more freely. The pulse rate will be less frequent, but care should still be exercised to find any additional focus and meet it. If the attempt is unsuccessful the area of dullness will be larger, and inspiratory crepitation will be heard. It is desirable to give two or three grains of calomel followed by a Seidlitz powder. If sufficient evacuation is obtained the purgative should not be repeated. The third morning the physical signs must be carefully determined and local applications carefully arranged to meet the conditions. On the third evening, unless there has been a marked improvement it may be advisable to apply a leech an hour before sleep, thus relieving the right heart, and then give a considerable quantity of water to satisfy the thirst and help elimination. If the patient does not come under treatment until the fourth day after the attack he will probably be in considerable distress, dyspnea, cyanosis, headache and dulness in the right auricle may be from 2 to 2½ finger breadths in the fourth space. This should be ascertained at once before an attempt is made to discover the amount of disease in the lungs. A larger number of leeches should be used than would have sufficed before. Venesection is often preferable, four ounces for a young adult, eight ounces for a strong man. Both lungs should then be carefully examined and ice bags applied and oxygen administered. On the fifth day if the treatment has been vigorous, leeches and ice give often a practical improvement, but severe cases can not be yet controlled. It may be advisable to limit the fluid given to avoid strain on the right heart and to give only malted milk powder dissolved in milk. It is desirable to again examine the right heart on the evening of the third day and if the condition of the heart is dubious, let the decision be for leeches again. If the patient has slept well and the right auricle does not measure more than two finger breadths, the leeches may be discontinued. If the patient has reached the fifth or sixth day of his illness, and neither bleeding nor ice bags have been employed, the symptoms are often very severe, the distress great and the outlook gloomy. The prognosis depends on the age, previous condition of health, the intensity of the infection and the action of the medical attendant. The first necessity is venesection and hypodermic injections of strychnin in three minim doses every four hours. This will doubtless cause improvement unless the case is a bad one, and he advises early consultation. In the case of an infant or an adult older than thirty years the danger to life is great and judicious treatment required from the very first. Pneumonia in adults usually ends with a rapid fall of temperature and a slowing of the pulse. In a child the subsidence is apt to be more gradual. It is necessary to watch for the quick diminution of temperature, especially in children. Ice bags should be gradually removed and the last taken off when the thermometer marks 100 F. There is a tendency to collapse in crisis, which must be kept in mind, and ice bags might be injurious. The crisis is often preceded by a remission of temperature that lasts only a few hours, hence it is well to watch the temperature. If it rises to 101 a single icebag should be used, and if to 103, two of them, the nurse carefully observing the case. If the temperature shows a persistent tendency to keep above the normal after the crisis, empyema should be suspected. The danger of overlooking such a condition is great and should always be kept in mind, and an exploring needle used if there is any room for doubt. Pleurisy may be treated with ice bags to the chest. The lecture also discusses the subject of appendicitis, and acute nephritis, giving illustrative cases.

3. **Dysentery.**—Todd, in this preliminary communication, describes the discovery of a dysentery antitoxin produced by growing the dysentery bacillus in a somewhat mildly alkaline broth. Certain animals, notably horses and rabbits, are highly susceptible to this toxin, which is fairly stable, though destroyed by an exposure to a temperature of 80 C. for an hour, but not at 70 or a lesser temperature. When injected into suitable animals, such as the horse, it gives rise to a powerful antitoxin. The combination of toxin and antitoxin *in vitro* does not take place immediately, but requires a certain time, and the rate of combination varies with the temperature.

4. **Gastrectomy.**—Moynihan reviews the records of this operation, which was first performed in America, and reports an unsuccessful case. He thinks that complete extirpation of the stomach is not merely brilliant surgical gymnastics, but has its proper place in surgery.

8. **Cancer and Its Embryonic Origin.**—Morris discusses the various theories of cancer and criticises and rejects the parasitic theory. The one he favors is that of Cohnheim, as modified by Durante, Nicoladoni, Ribbert and Senn, namely, the existence of congenital matrices of embryonic cells as well as postnatal formations, the maintenance of these foci and their arousal into activity from various causes. He goes at length into arguments in favor of this tumor-germ theory which escapes the objection raised against the local and constitutional theories and accounts for various phenomena, such as the transformation of benign into malignant tumors, better than the parasitic. It convinces us, he says, of the local origin of cancer and the curability of it if taken early.

9. **The Parasitic Theory of Cancer.**—Plimmer takes the opposite view, reviews the literature, his own researches and those of others and maintains that the parasitic theory can not be put out of consideration, for it offers the best explanation. He asserts that the clinical course of the disease, its beginning in one spot, its extension, to different parts by lymphatic or blood routes, the cachexia out of all proportion to the extent of the disease, the spread by contagion, occurrence in certain parts of the body and its return after years

of quiescence drive us to the parasitic theory. He also thinks that it offers the only hopeful outlook. The arguments that he brings up for it are the localization of cancer in certain moist and wooded districts, and in certain dwellings, the objective signs, the bodies found by himself, Gaylord and others and the inoculation experiments from man to animals and animals to animals, etc.

10. **Cancer and the Nervous System.**—Cheatle holds that he has proved a direct relation between cancer and the nervous system; that its spread and limitation to the skin and muscles bears a practical relationship to the presence of nerves and that the absence of nerves where normally they previously existed bears a marked relation to the limits of cancer. His article is very fully illustrated, especially as regards the nerve distribution of the areas occupied by rodent ulcer.

11. **Radium.**—Turner describes the properties of radium showing that it gives out a radio-active emanation and three kinds of rays: that it keeps itself at a higher temperature than its surroundings and emits heat at an estimated rate of about 100 calories per gram per hour. It is in its behavior antagonistic to some of the fundamental physical laws. The emanation is of the nature of a luminous gas, which can be condensed by intense cold and which imparts radio-activity to objects in its path; more than two-thirds of the heating effect of radium is due to this emanation, and 1 c.cm. would probably instantly melt down the glass tube which contained it. The *a*-rays consist of a stream of positively charged particles of mass about twice that of the hydrogen atom and projected with a velocity of about 20,000 miles a second. They have little penetrative power. The *b*-rays appear to resemble the cathode rays of a Crooke's tube, negatively charged, more penetrating than the *a*-rays and consist of particles of about 1/1,000 of the mass of a hydrogen atom and are powerfully actinic. The *g*-rays, or the gamma rays, are the most penetrating of all, and evidently resemble the Röntgen rays from a hard tube. Together with these qualities radium seems to manufacture the gas helium. With these physical qualities he then notices the therapeutic possibilities such as the suggestion of Mr. Soddy, that a consumptive patient should inhale the emanation so as to bring the remarkable agent in contact with the diseased lung. A few milligrams of radium bromid may be placed in water in a suitable inhaler and the emanation drawn into the lungs, but he gives warning against using such a remedy without previous medical sanction. Owing to the property the emanation has of imparting radio-activity, the effect of the inhalation would probably continue for a considerable time, for the air-passages will become radio-active. The radium rays have been found to be bactericidal with long exposure. The micro-organisms do not appear to be very susceptible, but it is dangerous to human tissue; one can not carry radium in one's pocket without bad effects. The effects of the rays on mice have been found to be fatal on the fourth or fifth day, the skin and brain being the most affected. The partially blind seem to be able to perceive by radium. The chief physiologic effects are summed up in the effects on the skin producing inflammations and ulcers, effects on the nervous system producing paralysis and death and the luminous effects produced in the partially blind. He thinks if it were possible to obtain radium in large quantities it would do away with the bulky *x*-ray apparatus, and if we could isolate it so that its effects would only be directed in useful ways we could light and heat our houses and run our ships with moderate quantities of the element.

12. **The Therapeutic Properties of Radium.**—Macintyre finds that the therapeutic action of radium has been mostly shown in lupus and rodent ulcer, but is useful in the same class of cases as is treated by the *x*-rays, Finsen light and high frequency currents. Experiments so far do not justify a comparison between the salts of radium and other agents. There is need of further investigation into its physiologic and other properties.

13. **The Treatment of Cancer.**—Cinnamic acid has been employed by Drage in the treatment of cancer by injection. Four cases are reported. The idea was to produce a leucocytosis and a secondary fibrosis of the tissues. These can usually be produced in pulmonary tuberculosis, but are more difficult in cancer. He claims the treatment is based on sound principles and that it has a future. He also uses another material, which he does not name, but promises to do so. It would seem that while the main growth was prevented from invading the adjacent tissue it was not completely checked.

14. **Paraffin Cancer.**—Kirk has noticed the frequent occurrence of epithelioma in workers in mineral oil. He thinks it is accounted for by the irritation produced. Such growths are less frequent than formerly on account of the use of different processes of purifying the shale from which the oil is produced. This is now done by superheated steam.

15. **Alcohol and Cancer.**—Newsholme analyzes the statistics of the United Kingdom Temperance and General Provident Institution which has its special departments for abstainers and non-abstainers. He finds that the latter furnished a far greater proportion of deaths from all causes, also from malignant diseases. The death rate from all causes of the three years 1891, 1896 and 1901 was 17.13 among abstainers and 23.52 per 1,000 lives among non-abstainers, while the death rate from malignant diseases was .95 among the former and 1.32 per 1,000 among the latter. In other words, if the death rate among non-abstainers in each instance be stated as 100 that of abstainers from all causes is 72.8 and from cancer 72. The various aspects and conditions which might modify the figures are discussed and the general results appear unchanged.

16. **Continuous Local Infection.**—Godlee notices certain conditions of chronic infection due to a suppurating appendix, and more especially those from pyorrhea alveolaris and reports a case illustrating what the latter lesion may produce and what it may simulate. Other causes of systemic infection are tuberculous disorders, such as absorption from tuberculous glands, systemic poisoning from leucorrhea, etc.

22. **Albuminuria and Diabetes.**—Pavy's article is continued from a former number, and the case reports are continued, illustrating the effect of the excessive use of alcohol in connection with diabetes. He says a moderate use of it may be beneficial, but an excess aggravates the diabetes and invites damage in which the kidney participates. The albuminuria which occurs in connection with the diabetes he points out may exist for a long time without leading to any symptomatic indication of its presence. Its presence, therefore, is not to be looked on as affording ground for apprehension in the same manner as when occurring under other circumstances.

24. **Antituberculous Serum and Vaccine.**—This article has been noticed editorially in THE JOURNAL, xli, p. 1479.

25. **Plague Inoculation.**—Forsyth gives the result of the use of Haffkine's plague prophylactic in over 30,000 cases showing the advantages of this measure. Both classes, the inoculated and uninoculated, lived under the same conditions. The death rate per cent. was only .22 among the inoculated but was 2.6 against the uninoculated. That it was not more effective he thinks is due probably to the inefficiency of the methods of vaccination, the subjects desiring to get along with as little trouble as possible. He criticises the inefficiency and half-hearted

measures that have been undertaken in India and believes with a proper appreciation of inoculation and common-sense methods of disinfection and segregation the disease may be stayed.

36. **Acute Insufficiency of the Suprarenals.**—Sergent published a description of this syndrome in 1899. He now reports 2 more cases with necropsy which corroborate the existence of a pseudo-meningitis originating in suprarenal insufficiency. There had evidently been a chronic affection of the suprarenals in each case, clinically latent, until fanned into a flame which proved rapidly fatal. One patient was a young woman, the other a man of 32. The symptoms suggested intoxication from the sudden suppression of the suprarenal functions. The syndrome may simulate also acute dyspepsia, poisoning, peritonitis, or cholera. The combination of pains in the epigastrium, anorexia, vomiting, extreme prostration and progressive emaciation, arterial hypotension and tachycardia indicated the suprarenal origin, but other symptoms such as the trigger attitude, the instability of the pupils, photophobia and pain on pressure of the eyeballs, cutaneous hyperesthesia, a plaintive cry and tardy headache, indicated meningitis, notwithstanding the absence of contractures, of Kernig's sign, and of the meningitis stripe, with the retention of consciousness. The necropsy disclosed that there was no meningitis, but merely a pseudo-meningeal reaction, a suprarenal encephalopathy. He calls attention to the differentiating value of the reflex capillary spasm, as he calls the white line that follows the attempt to elicit the meningitic stripe. He thinks that the arterial hypotension with peripheral capillary dilatation induces the exact reverse of what is observed in true meningitis. The mechanical excitation induces contraction of the capillaries. This sign is important for the differentiation of the suprarenal syndrome. In both the cases described the suprarenals had been entirely destroyed by tuberculous processes, secondary in one case and probably primary in the other. The meninges were intact in each case.

43. **Percussion in Diagnosis of Gastric Affections.**—This communication from von Ketly's clinic at Budapest states that percussion-auscultation has abundantly established its usefulness in more than 100 cases examined. The results were so incredible in 2 instances that they were regarded as failures of this method of functional diagnosis, but the operation disclosed that the remarkable abnormal condition indicated actually did exist. By this method the stomach outlines are traced in their natural position, size and form; it is simple and practicable, and is so perfectly harmless that it can be used where all other methods of functional diagnosis are contra-indicated. In combination with artificial insufflation of the stomach, percussion-auscultation imparts the most valuable information in regard to the muscular tone of the organ, distinguishing accurately between atony and hypertrophy. When the position of the greater curvature is determined by percussion-auscultation both before and during artificial distension of the organ, there is a difference of about 2 cm. in the normal stomach outlines in these conditions. If the difference exceeds 2 cm. the muscular tonicity is diminished. A difference less than 2 cm. indicates hypertrophy of the stomach musculature. We are able by this means to determine even slight degrees of atony which escape detection by the test meals or can be only uncertainly diagnosed by their aid. The information to be derived by means of percussion-auscultation in case of abdominal tumors is also extremely valuable. When the tumor is circumscribed its outlines can be accurately determined and its source of origin defined. A still further advantage of the percussion-auscultation method is that it enables manipulations to be dispensed with when necessary. Pesthy groups the various cases in his experience diagnosed by this method alone or in combination with others, giving the particulars of the findings in gastroptosis, dilatation, contracted stomach, etc. [Ivanoff has recently expatiated on the advantages of palpatory percussion, that is, learning to appreciate the percussion findings as experienced by the percussing muscles. He thinks that this refinement of percussion will be found very valuable in certain cases. His communication on the subject was mentioned in these columns recently, xli, page 1446, with special reference to his suggestion of the use of the tuning-fork for percussion-auscultation and palpatory percussion.—Ed.]

45. **Determination of Stomach Capacity by Means of the Manometer.**—Spanje describes a manometer which he has devised for the purpose of determining the capacity of the stomach in patients accustomed to the use of the stomach tube. The apparatus looks rather complicated in the cut, he remarks, but in reality it is extremely simple, inexpensive and easily constructed. After aspirating until the organ is empty, air is allowed to enter until the patient begins to experience a sensation of distension, the maximal manometer pressure being 6 to 8 mm. of mercury. Spanje reports the particulars in a number of cases thus examined. In one there had been evidences of stomach trouble for sixteen years, and every two or three days the patient, a man of 44, vomited undigested food, with lactic acid and free HCl. The manometer indicated a stomach capacity of 2,700 c.c. at a pressure of 6 to 8 mm. mercury. On the diagnosis of stenosis pylori and ectasia ventriculi a gastro-enterostomy and entero-anastomosis were done. A small, hard, movable tumor was found at the pylorus. The stomach capacity had declined to 1,200 c.c. when the patient was dismissed cured. In another case the patient complained of violent pain at a manometer pressure of less than 1 mm. mercury—the symptoms indicating stenosis pylori. Perigastritis was assumed in consequence of the pain and the small capacity of the stomach, and this assumption was confirmed by the operation in this and a number of other cases. In health the fasting stomach is entirely empty and contains no air—the walls evidently being in contact. Percussion of the empty stomach is therefore of little use.

[**The Borderland Centralblatt.**—The full title of this comparatively new journal is the "Centralblatt for the Borderland between Medicine and Surgery." It is issued irregularly as material accumulates. About 23 numbers have been issued in 1903, forming a volume of about 900 pages. It makes a specialty of comprehensive summaries of the international literature on the various subjects presented, with a running commentary by the reviewer. Each issue contains a number of abstracts from the borderland literature. It is in one sense a companion to the large Borderland Archives, better known as the *Mitteilungen a. d. Grenzgebieten*. Frequent reference is made to the work of the Americans in the articles in these publications.]

46. **Renal Abscess and Perinephritis.**—Herszky reviews 307 articles published on this subject of late years. The consensus of opinion is in favor of operating as soon as there is a well-founded suspicion of an abscess. The abscess formation is rapidly progressive and early intervention is required especially on this account. If the smallest abscess focus is left the incision has not accomplished its purpose, and Israel contends that the surgeon's task is not complete until he has exposed the kidney or its capsule so that it can be thoroughly palpated.

47. **Puerperal Eclampsia.**—Schnürer's review embraces the literature from 1890 to June, 1902, a total of 758 articles. The average occurrence of eclampsia ranges from 2.25 per cent. of all the births in Queirel's experience to .12 per cent. in Veit's. Schauta reports .25 per cent. in 134,000 births and Inojew .53 per cent. in 111,047 births, the general average being .45 per cent. Autochthonous exclampsia occurred on an average in .19 per cent., that is, once in 525 births, although Döderlein's experience has been nearly three times as favorable as this. Schnürer gives a number of tables showing the stage, age, mortality, etc. The eclampsia developed during the pregnancy in 20 per cent., during delivery in 59 per cent., and during the puerperium in 21 per cent. The affection is most common in Russia, occurring in the proportion of 1 to 73 and 1 to 150 births, while in England the average proportion is 1 to 750 and Döderlein, at Würtemberg reports only 1 to 3,561. The average mortality was 21.85 per cent. Stroganoff has no mortality to report in his 58 cases, Dührssen 21 per cent. in 200 cases, and Wirtz 78 per cent. in 43 cases. The mortality of the children averaged 36.56 per cent. Here again Stroganoff has no mortality, while Zweifel reports 33 per cent. mortality among 103 children, Dührssen 53.4 per cent. in 146 children and Wirtz 69 per cent. Twins were noted in 6.93 per cent. of all the cases of eclampsia, and a very large proportion of all the eclamptic women were primiparæ, the percentage ranging from 60 to 90 per cent., except in Inojew's experience in which it was 43.7 per cent. (Stroganoff's method of treating eclampsia was described in THE JOURNAL, xxxix, p. 727, 1902.)

50. **Operative Treatment of Tuberculous Peritonitis.**—Zesas concludes from his study of 69 articles that have been published on this subject, that it is risky to postpone operative intervention in tuberculous peritonitis in the hope of a spontaneous cure as it is of rare occurrence. An aseptic and cautious laparotomy with gentle detachment of adhesions never harms and frequently arrests the process or cures it. He reports 2 cases from his own experience in which complete cure has persisted for nine and five and a half years, both patients girls, 15 to 20 years of age.

54. **Multiple Neurofibromatosis.**—This comprehensive review is carried nearly through the entire year. It reviews the literature that has been published since Adrian's previous work on the subject in 1901. He concludes that the prognosis is not absolutely unfavorable so long as the central nervous system is not involved, or is not the exclusive seat of the affection. Some of the patients reach an advanced age, 60 to 88 years. The prognosis is obscured in many cases by the cachexia accompanying the condition which lowers the resistance to tuberculosis and other intercurrent affections. There is also a liability to malignant degeneration of the neurofibromata and a modification of the skeleton suggesting osteomalacia. The location of the tumors is also an important factor in the prognosis. Treatment is generally powerless, but avoidance of cutaneous irritations should be urged as a prophylactic measure and also other factors tending to depress the vitality. Local injections have had only transient effect. Operative removal offers little prospects of success on account of the tendency to recurrence. In one case on record resection of a tumor in the knee was followed by formation of tumors over the entire body. The recurrence is liable to present malignant characteristics. In one case treatment with suprarenal substance conquered the patient's asthenia, but the improvement was transient and the general condition grew worse as soon as the medication was suspended. Whitehouse has also reported improvement in one case under arsenic.

55. **The Leucocyte Curve in Appendicitis.**—In Federmann's experience the leucocyte curve has varied with the three forms of appendicitis, the simple, the perforative and the gangrenous. The differences are due to the intensity of the infection, the reacting powers of the organism and the local conditions. Large numbers of leucocytes invariably differentiated incipient peritonitis from ileus without complications. An early, very high leucocytosis, up to 40,000 or 50,000, seems to be characteristic of benign, gynecologic peritonitis. In cases of benign perforation with rapid encapsulation the very high leucocytosis noted at first materially subsides by the third day with the temperature and other symptoms. In diffuse suppurative peritonitis continuing a progressive course the hyperleucocytosis subsides in the same way, but the other symptoms persist and grow worse. A leucocytosis of 20,000 after the fourth day with other severe symptoms, speaks strongly in favor of deficient encapsulation with a tendency to spread. The same symptoms by the end of the first week or later positively indicate a more or less encapsulated process. A high leucocytosis is in itself a favorable sign, while small numbers of leucocytes accompanying other severe symptoms are the expression of an already established general intoxication, and hence suggest the gravest prognosis. Surgical intervention is still indicated, however. Federmann writes from the Moabit Hospital at Berlin and concludes with the detailed reports of 23 cases.

56. **Hemorrhoids in Children.**—Reinbach classes hemorrhoids as true angiomata cavernosa and thinks that the tendency to their development is congenital. He has been studying the microscopic structure in both adults and children and gives the particulars here of specimens derived from a girl of 8. He has encountered them a number of times in children. Purely venous congestion may induce a clinical picture very much like that of true hemorrhoids.

57. **Importance of the Parathyroid Glands.**—Walbaum's experiments on rabbits have demonstrated that the epithelial corpuscles have an important function, apart from that of the thyroid gland. The outer seem to have a greater vital significance than the inner ones. After their extirpation the rabbits exhibited convulsions and progressive cachexia, and became dull, the fur rough. When these glands were trans-

planted they healed in place, but degenerated and the animals succumbed as without transplantation.

58. **Idiopathic Dilatation of Esophagus.**—Lossen's experience includes 5 cases. All had developed on a nervous basis; in one case the cardio-spasm had been favored by chronic inflammation of the esophagus. Radioscopy is an invaluable aid for the differentiation of the condition. He applied Fleiner's method of feeding by the stomach tube with good results, combating the cardio-spasm by means of a tablespoonful of oil before each meal. When feeding through the tube can not be satisfactorily continued and rectal feeding is insufficient, he advises not to delay gastrostomy too long.

59. **Surgical Treatment of Chronic Ulcerative Colitis.**—Nehrkorn is convinced that an artificial anus—preferably at the flexure—is decidedly to be preferred to mere entero-anastomosis. He believes also that the formation of a valve fistula by the Kader-Gibson technic has many advantages. For irrigations in the after-treatment he uses chamomile tea, dilute alcohol solutions of salicylic acid and occasionally boric acid, tannin or nitrate of silver. He reviews the literature on the subject, the total cases reported numbering 30, to which he adds 4. They include several published in The Journal. The operation was undertaken on the right side in 16 cases, with 6 complete successes and 3 failures; and on the left side in 9, with 7 complete successes and only one failure. These results speak in favor of an anus at the flexure. He appends the case history of a rapidly fatal case of severe dysentery restricted to the colon. The prompt surgical intervention was unable to avert the fatal termination, but he thinks it was justified even in such a desperate case.

60. **Osmotic Pressure and Electric Conductibility of Organic Fluids.**—[Engelmann has previously stated that he had found the electric conductibility a surprisingly constant figure in 200 tests of the blood serum. In a case of bile fistula in which the bile was tested every two hours, the freezing-point and the electric conductibility varied in parallel proportions, the slightest change in either being accompanied by a corresponding modification of the other. The concentration and conductibility of segregated urine also parallel each other in health, with minute precision. He emphasizes that this affords a valuable means of controlling the findings of each by means of the other test, and is especially valuable as the conductibility can be tested with minimal amounts of urine. —Ed.] In the present article he reports further extensive research. The electric conductibility of the blood serum does not parallel the freezing-point in pronounced renal insufficiency. There does not seem to be any retention of electrolytes in these cases, while the concentration of the blood augments in proportion to the imperfect functioning of the kidneys. He also found that after intravenous infusion of 1,500 to 2,000 c.c. of a .6 per cent. salt solution the osmotic pressure of the blood speedily returned to its original value, even when it was high.

61. **Appendicitis Operations at Jena.**—Riedel advocates early operating as soon as the diagnosis of appendicitis is established, without waiting for hyperleucocytosis. He urges education of the public so that the affection will be recognized in its early stages, and provision made for careful transportation of the patient—preferring a hand-borne litter to the usual modes of conveyance in the country and small towns. A litter should be kept on hand the same as a fire engine, ready for emergencies in such places. The earlier the operation the smaller the incision required and the less risk in the intervention.

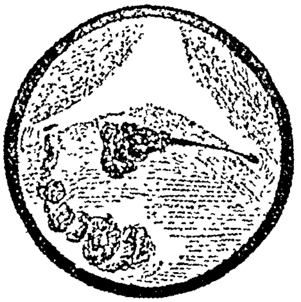
62. **Determination of Pressure in Right Auricle.**—Gaertner proclaims that it is possible to determine the pressure in the right auricle by observing the behavior of the veins in the arm when the arm is held upright. The veins become engorged when the arm is hanging down and collapse when the arm is raised. If the arm is raised very slowly it will be seen that the point at which the veins collapse is always at a certain level for a given person. The veins remain round and prominent as the arm is raised until this level is reached, when the walls flatten out. This point of subsidence of the veins is in health always at the level of the sternal end of the third, fourth or fifth ribs. The veins form a manometer column which allows the condition of the blood column within to be estimated. The slightest positive pressure distends the walls of the veins while they flatten out as soon as the pressure is zero or negative. In pathologic conditions the veins do not collapse until the arm reaches the level of the jugular vein, the eye or even the top of the head in extreme cases. The findings of this test invariably harmonized with other presumptive evidence of stagnation in the right heart. The subject sits erect, the back supported, the sternum vertical. The veins on the back of the hand and forearm are the best adapted for the test. The arm is raised passively by the examiner, with abduction at the shoulder, the muscles relaxed as much as possible, and both arms are tested in turn and several times in succession. The difference between normal and pathologic conditions is so marked that trifling inaccuracies are negligible. Gaertner uses a tape measure to determine the number of centimeters above the zero point—the sternal attachment of the upper margin of the fifth rib—and slips a pencil through a ring at zero in the tape measure for convenience in sighting the rib. He calls the pressure in the auricle VD (Vorhofsdruck), and expresses it in centimeters, representing the number of centimeters, above the zero point, at which the "vein phenomenon" occurs. In valvular affections the pressure is plus 9, 19, 20 and 27. The highest pressure he ever encountered was 37 cm. In some cases this increased VD is the only objective sign of disturbances in the circulation. It is so striking that it is peculiarly adapted to impress the laity when necessary to convince others of the existence of disturbances in the circulation or respiration. It not only affords a certain diagnosis of stagnation in the right heart but enables us to measure its degree and its modifications as they occur under treatment. He also found that the test can be made with the legs, the subject reclining on a flat surface, the legs below the knee hanging down over the edge. The "vein phenomenon" occurs at the same level with both legs and arms in health, indicating that the intra-abdominal pressure may be regarded as nil. A difference between the findings with legs and arms will afford insight into the intra-abdominal pressure in pathologic conditions. When extreme accuracy is desired he uses a wooden standard with a sliding horizontal bar to determine the VD.

63. **Nile Blue Test for Carbonic Dioxid in the Air.**—Heidenhain describes a number of striking experiments that can be

made with this reagent. Among others, if a little of the brilliant orange solution of Nile blue is poured on a sheet of blotting paper held by one corner, it changes instantaneously to blue in the presence of carbonic dioxid in the air. He prepares the solution for this experiment by dissolving the stain in 80 per cent. alcohol and then shaking into it a little finely pulverized calcium hydrate (CaO). The result is a brilliant orange. It is so sensitive that even pouring the fluid into another vessel alters the tint as it takes up the carbonic dioxid from the air so quickly.

69. **Therapeutic Trials of Fluorescent Substances.**—THE JOURNAL has already mentioned von Tappeiner's announcements that certain fluorescent substances, in themselves not at all bactericidal, became extremely so when fluorescence was induced in them by sunlight or diffuse daylight. Further research has demonstrated that this action is effectual also on enzymes and certain toxins. Ricin, for instance, loses its characteristic property of agglutinating red corpuscles after being exposed to this fluorescence. Among the various fluorescent substances tested, eosin was the most pronounced in its action, not only on enzymes but also on toxins and on living cells. It was consequently selected for therapeutic trials. Superficial lesions were painted with a 5 per cent. aqueous solution of eosin and then exposed to the sunlight. Three cases of carcinoma, 10 of condylomata lata, 5 of lupus and several of other cutaneous affections were treated by this combination. In one case of destructive carcinoma of the nose and cheek on a woman of 76, after four weeks of this treatment the edges of the lesion have subsided, the suspicious zone of infiltration around it has completely vanished, the interior of the cavity shows fresh, healthy granulations, and there is already a strip of healthy cicatricial tissue 8 to 13 mm. extending through a part of the growth. A rodent ulcer of eighteen years' standing cleared up under six weeks of treatment to a healthy granulating surface with nothing to suggest the former condition, and two more weeks will evidently complete the transformation into healthy cicatricial tissue. The third case of cancer has now, after sixty days of treatment, a smooth cicatrix in the place of the former succulent, fast proliferating carcinomatous growth on the face. In lupus the lesions rapidly healed under the treatment when they were close to the surface. Deep-seated nodules were not benefited. The superficial ones, whether large or small, ulcerating or not, seemed to display the same tendency to heal as the carcinomatous tissue. Sound tissue is not materially affected. Eosin was given internally at the same time, but the particulars of this internal administration are not reported. Condylomata lata on the female genitalia rapidly subsided under this local treatment and a primary syphilitic lesion on the tongue also healed and the accompanying tumefaction of the regional glands spontaneously subsided. No further manifestations of the syphilis were noted in this case until sixteen weeks later, when a few roseola patches became apparent on the abdomen. A case of tuberculosis of the testicle and scrotum in a lad of 14 was treated in this way. The tumor gradually subsided and tubercle bacilli could no longer be found in the secretions after four weeks. Eosin was injected into the corresponding thigh. This case is still under treatment. All pains vanished soon after the eosin was first applied.

70. **New Method of Functional Diagnosis of the Kidneys.**—Voelcker and Joseph describe a simple means of determining the functional activity of each kidney without catheterization of the ureters or the use of a urine segregator. It consists in the injection of a stain which is eliminated exclusively by the urine, is non-toxic and passes unchanged through the body, not being transformed like methylene blue into colorless compounds, while it is not so soluble as the latter and hence does not diffuse through the tissues and organic juices other than the urine. They express surprise that this well-known stain—indigo carmin—has not been applied before to functional diagnosis of the kidneys as its advantages over other stains are so obvious. The maximum elimination through the urine occurs in thirty minutes, gradually subsiding to the end of the second hour, after which only minimal amounts can be detected to the end of the tenth hour. They describe their experiments and trials on dogs and then the application of the new method in the clinic. The technic preferred is the injection into the gluteal muscles of a fresh, 4 per cent. solution of carminum ceruleum (identical with indigotine I and indigo carmin). The solution is made with .4 gm. of indigo carmin in 10 c.c. of physiologic salt solution, injecting 4 c.c., warm. The fluid is rather a suspension than a solution. Twenty to thirty minutes after the injection the cystoscope is introduced into the bladder and the jets of strikingly blue urine can be seen emerging from the mouths of the ureters. The jets appear with some force and are directed toward the median line, and then the blue fluid gradually sinks to the bottom of the bladder. Even the novice in bladder examination has an unmistakably clear picture before him of the functioning of the kidneys. The cut shows this picture in a normal bladder. The jet is just spurting from one ureter, while that from its mate is sinking to the bottom. A number of instances are reported showing the importance of the information thus derived. In one case the symptoms indicated tuberculosis of the bladder. The lesions were so extensive that catheterization of the ureters would have been impossible. Attacks of pain developed in the right kidney region, with fever and cerebral symptoms. The right kidney was much enlarged. The indigo carmin test showed that no urine was being eliminated from the left kidney, which had caused no symptoms and was apparently normal. Consequently the idea of operating on the enlarged right kidney was abandoned and the fever ascribed to meningitis. The necropsy disclosed that the left kidney—which had given no clinical trouble—was in complete caseous degeneration, while the right proved to be the only sound organ in the body. The new test saved the patient from an inevitably useless operation, to say the least. In another case a papilloma in the bladder nearly covered the mouth of one ureter and the patient suffered from hematuria. Other symptoms suggested the possibility that the papilloma in the bladder was merely a metastasis from the kidney, but no means were known by which the condition of the kidneys could be decided as the growth prevented catheterization of the ureter. Three years later the patient returned with pronounced anemia from the recurring hematuria, hemoglobin 20 per cent., and new papillomatous growths in the bladder. The indigo carmin test was applied, and at once blue urine spurted with equal force and of the same tint from each ureteral orifice, showing that the kidneys were functioning normally. The patient was restored to health by extirpation of the excrescences in the bladder. In these 2 cases this test is the only one known with which functional diagnosis was possible. Other cases are related showing the superior simplicity and ease of the test in comparison to others. It is particularly valuable when the ureter mouths are hidden from any cause, especially with prolapse of pelvic organs or hypertrophied prostate. The type of the elimination, the intervals, size, force and other properties of the jets are also valuable indices of the kidney functioning, impossible to mistake, and impossible to determine by other methods to the same extent. It may prove to be feasible to determine the specific gravity of the blue fluid from each kidney by injecting some fluid into the bladder whose specific gravity approximates that of the urine, noting whether the blue urine from one ureter rises or falls with the blue cloud from the other, or whether there is a difference between their behavior in this respect. Mu time has been spent in the endeavor to establish certain



ards of force, tint, etc., characteristic of certain affections of the kidneys, but this research is not yet concluded.

71. **Ultra-Microscopic Detection of Albumin.**—Raehlmann describes tests with the new microscope with intense focal illumination from the side which shows up particles only 1 to 10 microns in diameter. He has found that the supposedly dissolved particles of albumin in solutions of albumin in reality retain their typical identity and can be inspected through this microscope. This is true of all solutions of albumin, including the urine in albuminuria. All these particles are in constant motion. The transformation of glycogen into dextrin, grape sugar, etc., under the action of certain reagents can be watched under this microscope, although the fluid to the eye shows no indication of turbidity or precipitation.

72. **Action of Roentgen Rays on Animals.**—Heineke reports experimentation which showed that mice, rabbits and guinea-pigs succumbed in a few days after prolonged exposure to radium and Roentgen rays. The findings in the organs, with the exception of the spleen, were negative, but the spleen was always found small and dark colored, with other changes, indicating that the rays had a destructive action on the red corpuscles.

75. **Primary Tuberculosis by Way of the Intestines.**—Wagener found primary tuberculous infection of the intestinal or mesenteric glands in 13, that is, in 17.1 per cent. of 76 child cadavers, with discovery of the tubercle bacilli. Similar lesions were found in 3 others, but without the bacilli, making a total of 21.1 per cent. in which primary tuberculosis of these glands was manifest.

79. **Romberg Sign and Muscle Sense.**—Mannini describes a case out of several in his experience in which the Romberg sign was marked but without any evidences of disturbance in the muscle sense. This sign is not, therefore, symptomatic of a lesion in the muscle sense in all cases.

80. **Polyvalence of Serums.**—Gay reports rapid recovery in 2 cases of pneumonia after injection of antidiphtheria serum. He details the particulars of the cases before and after the injections and thinks that the benefit was unmistakable. He injected the serum also in a severe case of meningitis, but without arresting its fatal course.

83. **Relapses in Pneumonia.**—Lovera's 3 patients were 19, 38 and 61 years old, and the relapse occurred four, five and seven days after the crisis and apyrexia. The second attack terminated by lysis in each case. He has had another patient who has passed through eight attacks of pneumonia.

85*a*. **Endovenous Injections of Sublimate.**—Maragliano states that the experience at his clinic has shown that these injections can be made without the slightest inconveniences if a large vein is selected for them, and they are made in such a way that the blood continues to flow through the vessel and thus mixes continually with the fluid injected. The solution must be weak, 1 to 10,000 or 1 to 5,000, or even 1 to 1,000 is harmless if the above rules are strictly followed. He injected from 1 to 5 mgm. of sublimate a day in progressing doses in man, examining the blood from day to day. No changes could be detected in the blood except a slight leucocytosis. From experimental research on animals he concludes that the minimal toxic dose is 15 mgm. per kilogram in a rabbit. Intoxication with sublimate has a tendency to destroy the blood corpuscles, but this has nothing in common with the therapeutic doses of sublimate. The slow, minimal therapeutic intoxication induces a leucocytosis which probably generates immunizing substances active against both bacteria and toxins. This assumption harmonizes perfectly with what is observed after endovenous injections of sublimate in certain infectious diseases. They unmistakably increased the resisting powers of animals injected, conferred agglutinating power on the serum and preserved the animals against toxic doses of bacterial toxins. He succeeded in saving the animals from the results of experimental diplococcus and streptococcus peritonitis and from anthrax by endovenous injection of 1/50 mgm. of sublimate per kilogram in a weak solution. This result was obtained both by preliminary injections of small repeated doses, as well as by postponing the injections until after the infection. The researches reported establish the efficacy of small doses, and that the action of the drug is due not to its bactericidal power, but to the increase in the organic resistance and the production of antitoxic material. Other drugs were tested in endovenous injections, and the dosage found for tincture of iodin, antipyrin, Fowler's solution, etc. One patient with rebellious hemoptysis was treated by endovenous injection of 150 c.c. of a 2 per cent. solution of gelatin, which arrested the hemorrhage almost instantaneously. These researches were conducted mostly by Mariani and included much experience with endovenous injection of oxygen, demonstrating its efficacy in certain conditions and its harmlessness.

85*b*. **Defense of the Organism Against Tuberculosis.**—Live tubercle bacilli were injected into the subcutaneous connective tissue in various animals, and their fate studied. Sooner or later all were swallowed by leucocytes. This occurred most promptly in the dog—in less than five days—and most slowly in the guinea-pig. The phagocytosis was more rapid and pronounced in the animals previously artificially immunized. Tubercle bacilli injected directly into the lung were also destroyed by phagocytosis.

85*c*. **Immunization Against Tuberculosis.**—Maragliano describes his researches in this line which he has been conducting since 1893. He remarks that he has now in his laboratory several rabbits which are immunized to such an extent that they are able to resist endovenous injections of fresh cultures of the most virulent tubercle bacilli. The method of immunization adopted by Behring differs from that with which Maragliano has been working for several years since he established the possibility of immunizing animals in 1895. He has found lately that the serum of immunized animals may attain remarkable agglutinating power. One cow agglutinates at 1 to 400 and one rabbit at 1 to 2,000. The serum loses its agglutinating power if heated to 55 and 60 C., but regains it on addition of normal serum. Its antitoxic power is not affected by warming. The presence of tuberculous poisons, proteins and toxins, in a serum retards or prevents agglutination. The antitoxic and agglutinating properties are not always parallel. After injection of an emulsion of living tubercle bacilli into the peritoneum of guinea-pigs the bacilli remain free in the peritoneal cavity and are not taken up by the leucocytes to any extent, although there is slight leucocytosis. Preliminary injection of tuberculin prevents the leucocytosis, but does not affect the phagocytosis. Injection of a fatal toxic dose of tuberculin neutralized by antitoxic serum induces a permanent leucocytosis and facilitates phagocytosis. Preliminary injection of antitoxic serum induces marked leucocytosis and intense phagocytosis. Marzagalli and Figari of the clinic have succeeded in extracting from the protoplasm of living and virulent bacilli a substance with which they immunize rabbits, their serum acquiring high agglutinating and bactericidal powers. This substance is sterile and contains no bacilli. When injected into rabbits and guinea-pigs by any route it does not cause either local or general reaction, and no traces of tuberculous lesions can be discovered later. The serum of animals thus immunized agglutinates homogeneous cultures of tubercle bacilli in the proportion of 1 to 2,000 (Courmont-Arloing method). These serums lose their agglutinating power in great measure when heated to 60 C. It is banished completely by keeping them at this temperature for three hours, but strange to say, they reacquire the agglutinating power again by the addition of even a small quantity of normal serum, *per se*, free from any clumping power. These serums added to cultures of tubercle bacilli check their development and colonies transplanted are unable to grow further. Virulent tubercle bacilli treated with these serums for four hours to five days and then injected into animals either under the skin or into the peritoneum or a vein, do not induce infection. The animals survive while all the controls die in less than thirty days. A number of rabbits and guinea-pigs in the laboratory are still thriving and increasing in weight, although they have been repeatedly injected during the course of three months with virulent bacilli treated with these serums. They evidently contain antitoxins and antibodies in conspicuous amounts and are extremely bactericidal besides. Maragliano regards these facts as a new victory in the potency of serums, which may be fraught with new and great therapeutic significance. The fluid with which the serum is obtained is derived from the protoplasm of tubercle bacilli and is able to substitute in practice the homogeneous cultures required by the Courmont-Arloing technic of agglutination tests. This places these tests within easy reach of the general practitioner. Any serum endowed with agglutinating power causes precipitation with this fluid. The suspected serum is placed in a test tube and above it a layer of this solution of bacillus pulp. A ring of coagulation forms at the point of contact if the serum possesses clumping power and not otherwise.

85*d*. **Further Research on Tuberculosis.**—Among the other subjects studied and described may be mentioned the morphologic modifications of the tubercle bacillus on various media; the toxic action of bacilli freed from fats; the presence of the bacilli in the circulating blood and in the urine, and extensive experimental research on tuberculosis in fowls and cattle. Sciallero had charge of research on injection of bacilli into various tissues and announces that there is little if any defensive reaction when living bacilli are injected into the tissues as the products of the vital activity of the bacteria have a demoralizing and destructive action. The bodies of the dead bacilli, *on the contrary, when injected into animals* stimulate the cells to produce materials for defense. The method of injecting a suspected fluid into the mammary glands of guinea-pigs suckling young was given a trial. Jemma thus injected some cerebrospinal fluid from three subjects with tuberculous meningitis. The scanty bacilli in the fluid rapidly proliferated in the mammary glands, and in less than a week were clearly evident in every instance. This technic is particularly useful for comparatively rapid differentiation in dubious cases, as it is so simple and certain. Further research has confirmed the importance of the size of the heart for the prophylaxis and prognosis of tuberculosis. Lanza found that the eosinophiles increased in every case examined, parallel with the progress of recovery. His tests were made with the serum from blisters, the subjects all children. Scanty bacilli in urine were detected by adding a little blood serum to a quart of urine, boiling, decanting the fluid and treating the coagulated sediment with gastric juice, then centrifuging and examining the sediment for bacilli.

85*e*. **Serotherapy of Tuberculosis.**—*In this as in the previous* years the adult patients with advanced tuberculosis were not benefited permanently by the treatment with serum from the immunized animals. As soon as they regained a little strength they abandoned treatment and returned to their occupations. The results in children were much better. In 3 out of 5 children with pulmonary tuberculosis treatment with the tuberculosis antitoxin has resulted in a permanent clinical cure. The other two with the acute bronchopulmonary form were not benefited. Among 38 out-patients there have been 6 clinical cures and 21 improvements, some of them amounting *almost to a cure. Maragliano in conclusion reiterates his* former assertions that nine years of experience have only confirmed him in the assumption that serum treatment is the only possible method of cure and that its success depends on the co-operation of the organism. He deplores the number of lives lost every year that might have been saved by serum treatment if the profession would abandon their prejudices against it and institute it in time. His assistants have demonstrated that the serum can be administered by the mouth, which removes one of the greatest objections against it. Thirteen patients in the clinic were treated by this route alone, and in 2 there was a clinical cure, although one was a febrile case. Five out-patients were also treated by the mouth alone, and in 2 there has been a clinical cure. He is confident that his research on the immunization of human beings will soon be crowned with success, although he does not care to publish anything further in regard to it at present.

88. **Sponge Irrigator.**—Fazzari's instrument aims to apply medication to the lesions in the urethra for hours at a time and exactly at the points where it is needed. A metal tube screws into a curved tip which fits into the bladder. A small cylinder cut from a sponge slips over this tube and a metal sheath fits over the tube and sponge, made in halves which fit together, the whole forming an instrument like an ordinary catheter when put together. It is inserted into the urethra and the outer sheath is then removed, one half at a time. The sponge is then moistened with the desired antiseptic through the central tube, the fluid impregnating the sponge through the holes beneath it.

89. **Scarlet Fever.**—In the epidemic described by Berghinz there were about 90 cases of true scarlet fever; the majority were marked by an acute, hemorrhagic nephritis. In another series of cases the hemorrhagic nephritis occurred alone, without any scarlet fever or other infectious preliminaries, but the development of true scarlet fever then or later in other members of the family indicated its nature. In some cases the hemorrhagic nephritis occurred with a measles-like rash. In another there was *no exanthem* but a suppurating mastoiditis accompanying the acute, hemorrhagic nephritis. De Fabritiis reports an epidemic of scarlet fever marked by its benign character, but insists that the way in which the epidemic still persists imposes the necessity for prophylactic measures the same as during a more malignant epidemic. Some modification of the soil may entail virulency at any time.

92. **Auto-Serotherapy of Pleuritis with Effusion.**—Five patients were treated by Donzello by withdrawal of 5 c.c. of the pleural effusion and immediate injection of 3 c.c. of the same under the skin of the forearm or abdomen. The patients recovered and he is convinced that this treatment was responsible for the prompt absorption of the effusion and the copious diuresis that followed. In one case he was obliged to aspirate the effusion owing to serious complications on the part of the lungs, but it did not collect again.

94. **Puncture of Spleen for Early Diagnosis of Typhoid.**—Michelazzi advocates puncture of the spleen in dubious cases as the best means of differentiating typhoid. It is superior to making cultures from the venous blood as there are liable to be associated micro-organisms, while the typhoid germs usually locate exclusively or principally in the spleen. Puncture of this organ is simple and harmless.

99. **Suprarenal Extract.**—Migliacci presents arguments to prove that suprarenal extract is as much a specific for akinesis of the muscular system as strychnin is for akinesis of the nervous system.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Medical Dispensary of the Jefferson Medical College. Volume IV. December, 1903. Diseases of Digestive Tract and Allied Organs. Liver, Pancreas and [illegible]tures, Dislocations, Amputations, Su[illegible] Orthopedics—Genito-Urinary Diseas[illegible] Physiology—Hygiene—Practical Therapeutic Referendum. Cloth. Pp. 444. Price, $2.50. Philadelphia and New York: Lea Brothers & Co. 1903.

THE LYMPHATICS. General Anatomy of the Lymphatics, by G. Delamere. Special Study of the Lymphatics in Different Parts of the Body, by P. Poirier, Professor d'Anatomie a la Faculté de Médecine a Paris, Chirurgien des Hôpitaux, and B. Cunéo, Professeur agrégé a la Faculté de Médecine de Paris. Authorized English Edition by Cecil H. Leaf, M.A., M.B. (Cantab.) F.R.C.S. (Eng.), Assistant Surgeon to the Cancer Hospital. With 117 Illustrations and Diagrams. Cloth. Pp. 301. Price, $5.00 net. Chicago: W. T. Keener & Co. 1903.

DEPARTMENT OF PUBLIC HEALTH AND CHARITIES, Having the Care, Management, Administration and Supervision of the Charities, Almshouse, Hospital and All Other Similar Institutions, the Control or Government of Which Is Intrusted to the City. The Mayor of Philadelphia, Hon. John Weaver. Director of Public Health and Charities, Edward Martin, M.D. Assistant Director, Mr. George W. Sunderland. Philadelphia Hospital Superintendent, Robert H. Smith. Chief Resident Physician, M. H. Biggs, M.D. Cloth. Pp. 178.

TEXT-BOOK OF OPERATIVE SURGERY: By Dr. Theodore Kocher, Professor of Surgery and Director of the Surgical Clinic in the University of Bern. Authorized Translation from the Fourth German Edition. By Harold J. Stiles, M.B., F.R.C.S. Edin., Surgeon to the Royal Edinburgh Hospital for Sick Children. With 255 Illustrations. Cloth. Pp. 440. Price, $5.00. London: Adam and Charles Black. New York: The Macmillan Co. 1903.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume VII. Illustrated by Chromo-lithographs and 688 Half-tone and Wood Engravings. Cloth. Pp. 951. Price, $7.00 per volume. New York: Wm. Wood & Co. 1904.

A COMPEND OF DENTAL PATHOLOGY AND DENTAL MEDICINE, Containing the Most Noteworthy Points on the Subjects of Interest to the Dental Student and a Section on Emergencies. By George W. Warren, A.M., D.D.S., Professor of Principles and Practice of Operative Dentistry, Penn. Coll. of Dental Surgery, Philadelphia. Fourth Edition, Illustrated. Cloth. Pp. 180. Price, 80 cents. Philadelphia: P. Blakiston's Son & Co. 1903.

ESSENTIALS OF PELVIC DISEASES WITH ILLUSTRATIVE CASES. By E. Stanmore Bishop, F.R.C.S. Eng., Hon. Surg. Ancoats Hospital, Manchester. And an Appendix on Examination of Blood, etc. By Charles H. Melland, M.D., (Lond.) M.R.C.P., Hon. Physician Acoats Hospital, Manchester. Cloth. Pp. 297. Price $3.00 net. New York: William Wood & Co. 1903.

COMPEND OF DISEASES OF THE EAR, NOSE AND THROAT. By John Johnson Kyle, B.S., M.D., Lecturer on Otology, Rhinology and Laryngology and Assistant to the Chair of Surgical Pathology in the Medical College of Indiana. 85 Illustrations. Cloth. Pp. 280. Price, $0.80. Philadelphia: P. Blakiston's Son & Co. 1903.

FOURTH ANNUAL REPORT OF THE WORK OF THE CANCER LABORATORY of the New York State Board of Health. Conducted at the Gratwick Research Laboratory, University of Buffalo. For the Year 1902-3. Transmitted to the Legislature February 1, 1903. Paper. Pp. 161. Albany: Evening Union Company. 1903.

HOW TO ATTRACT AND HOLD AN AUDIENCE, A Popular Treatise on the Nature, Preparation and Delivery of Public Discourse. By J. Berg Esenwein, A.M., Lit. D., Professor of the English Language and Literature in the Pennsylvania Military College. Cloth. Pp. 272. Price, $1.00. New York: Hinds & Noble.

THE RIGHT TO LIFE OF THE UNBORN CHILD. A Controversy Between Prof. Hector Treub, M.D., Reverend R. Van Oppenraay, D.D., S.J., Prof. Th. M. Vlaming, M.D. With an Appendix on a New Method of Operating, Ejecting the Fetus Alive. Cloth. Pp. 125. Price, $1.00. New York: Joseph F. Wagner.

LIST AND STATION OF THE COMMISSIONED AND WARRANT OFFICERS OF THE NAVY OF THE UNITED STATES, AND OF THE MARINE CORPS on the Active List and Officers on the Retired List Employed on Active Duty, July 1, 1903. Paper. Pp. 131. Washington: Government Printing Office. 1903.

BLOOD-PRESSURE IN SURGERY, An Experimental and Clinical Research. The Cartwright Prize Essay for 1903. By George W. Crile, A.M., M.D., Professor of Clinical Surgery, Western Reserve Medical College. Cloth. Pp. 422. Price, $4.00. Philadelphia and London: J. B. Lippincott Co. 1903.

A COMPEND OF PATHOLOGY, General and Special. A Student's Manual in One Volume. By Alfred Edward Thayer, M.D., Professor of Pathology, University of Texas. Second Edition, Containing 131 Illustrations. Leather. Pp. 711. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1903.

THE PRINCIPLES OF "OPEN-AIR" TREATMENT OF PHTHISIS and of Sanatorium Construction. By Arthur Ransome, M.D., M.A. (Cantab.), F.R.C.P., F.R.S., Hon. Fellow of Gonville and Caius College, Cambridge. Cloth. Pp. 104. Price, 5 shillings. London: Smith, Elder & Co. 1903.

FIFTEENTH EDITION OF THE OFFICIAL REGISTER AND DIRECTORY OF PHYSICIANS AND SURGEONS IN THE STATE OF CALIFORNIA: Revised and Published by the Medical Society of the State of California. Nov. 15, 1903. Cloth. Pp. 242. San Francisco: The Hicks-Judd Co.

THE AFTER-TREATMENT OF OPERATIONS: A Manual for Practitioners and House Surgeons. By P. Lockhart Mummery, F.R.C.S. Eng., Demonstrator of Operative Surgery, St. George's Hospital. Cloth. Pp. 221. Price, $2.00 net. New York: Wm. Wood & Co. 1903.

MEDICAL AND SURGICAL REPORTS OF THE BOSTON CITY HOSPITAL: Fourteenth Series. Edited by Herbert L. Burrell, M.D., W. T. Councilman, M.D., and Charles F. Withington, M.D. Paper. Pp. 178. Boston: Published by the Trustees. 1903.

HANDBOOK OF DISEASES OF THE EAR, for the Use of Students and Practitioners. By Richard Lake, F.R.C.S. Eng., Surgeon Royal Ear Infirmary. With 3 Colored Plates. Cloth. Pp. 232. Price $2.00 net. New York: Wm. Wood & Co. 1903.

TRANSACTIONS OF THE AMERICAN SURGICAL ASSOCIATION. Volume the Twenty-first. Edited by Richard H. Harte, M.D., Recorder of the Association. Cloth. Pp. 630. Printed for the Association. For sale by Wm. J. Dornan, Philadelphia. 1903.

TWENTIETH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF INDIANA for the Fiscal Year Ending Oct. 31, 1901, and the Statistical Year Ending Dec. 31, 1901. To the Governor. Cloth. Pp. 687. Indianapolis: Wm. B. Burford. 1903.

ELEMENTS OF SURGICAL DIAGNOSIS: By A. Pearce Gould, M.S. Lond., F.R.C.S. Eng., Surgeon to the Middlesex Hospital. Third Edition. Revised and Enlarged. Cloth. Pp. 607. Price, $2.00 net. Chicago: W. T. Keener & Co. 1903.

THE FIFTH ANNUAL REPORT OF THE INDIANA STATE BOARD OF MEDICAL REGISTRATION AND EXAMINATION for the Year Ending December 31, 1902. To the Governor. Cloth. Pp. 269. Indianapolis: Wm. B. Burford. 1903.

TRANSACTIONS OF THE STATE MEDICAL ASSOCIATION OF TEXAS. Thirty-fifth Annual Session held at San Antonio, Texas, April 28, 29 and 30, and May 1, 1903. Cloth. Pp. 635. Austin, Texas: von Boeckmann-Jones Co. 1903.

MEDICO-CHIRURGICAL TRANSACTIONS, Published by the Royal Medical and Chirurgical Society of London. Volume LXXXVI. (Second Series, Volume LXVIII.) Cloth. Pp. 570-39. London: Longmans, Green & Co. 1903.

TRANSACTIONS OF THE INDIANA STATE MEDICAL SOCIETY, 1903. Fifty-fourth Annual Session Held in Richmond, Ind., Thursday and Friday, June 4 and 5, 1903. Cloth. Pp. 489. Indianapolis: Wm. B. Burford, 1903.

REPORT OF THE SURGEON-GENERAL U. S. NAVY, Chief of the Bureau of Medicine and Surgery to the Secretary of the Navy. 1903. Paper. Pp. 295. Washington: Government Printing Office. 1903.

THIRTY-THIRD ANNUAL REPORT OF THE CENTRAL STATE HOSPITAL OF VIRGINIA for the Fiscal Year Ending Sept. 30, 1903. Paper. Pp. 83. Richmond: J. H. O'Bannon, Supt. of Public Printing. 1903.

ANNUAL REPORT OF THE HEALTH DEPARTMENT OF THE CITY OF LOUISVILLE, KY., for the Fiscal Year Ending Aug. 31, 1903. Paper. Pp. 76. M. K. Allen, M.D., Health Officer, Louisville, Ky.

U. S. DEPARTMENT OF AGRICULTURE. Nineteenth Annual Report of the Bureau of Animal Industry for the Year 1902. Cloth. Pp. 651. Washington: Government Printing Office. 1903.

TRANSACTIONS OF THE NORTH DAKOTA STATE MEDICAL SOCIETY for the Year 1903 and List of Members. Paper. Pp. 59.

## New Patents.

Patents of interest to physicians, Nov. 17 to 24:

744510. Making albuminoid substances from maize. Eugene Donard and H. Labbe, Paris, France.
744512. Suspensory bandage. Edward R. Drake, DeLand, Fla.
744096. Ozonizer. Marius Otto, Paris, France.
744603. Atomizer. John D. Pierce, Philadelphia.
744613. Ophthalmometer or other tables. Wm. F. Reimold. Philadelphia.
744126. Surgical chair. Wm. I. St. John, Detroit.
744656. Fountain syringe. Ottile Wider, Washington, D. C.
744666. Carbonizing apparatus. Bernhard Zwillinger, New York
744667. Carbonizing. Bernhard Zwillinger, New York.
744668. Apparatus for carbonizing. Bernhard Zwillinger, New York.
744569. Carbonizing and cooling down the charge. Bernhard Zwillinger, New York.
744670. Carbonizing material. Bernhard Zwillinger, New York
744713. Device for correcting spinal curvature. Carl G. P Blomqvist, Omaha.
744718. Massage appliance. Isabel Cassidy, New York.
745097. Preparing fat-free casein. Otto Eberhard, Ludwigslust, Germany.
745105. Pasteurizer. Aage Jensen, Topeka, Kan.
744766. Fumigating candle. Ernest Kimmich, Detroit.
745021. Movement-cure apparatus. John J. Lewin, Palo Alto. Cal.
744782. Sterilizer. Sidney E. Morse. New York.
745227. Label retainer for salve boxes, ointment boxes, etc. Clarence A. Myers, Atlantic City, N. J.
744978. Disinfectant vessel. Heinrich Pfluger, Frankfort-on-the M[illegible]
[illegible] limb. James F. Rowley, Chicago.
[illegible]ppliance. Albert V. Todd, Denver.
[illegible]bandage. Justin K. Toles, Chicago.
[illegible] in electric therapeutics and electric treatment. Louis Williams, Seattle, Wash.

### TYPHOID FEVER.

SOME UNCONSIDERED HINDRANCES IN ITS PROPHYLAXIS.*

JOHN S. FULTON, M.D.
BALTIMORE, MD.

For fifty years we have known that drinking water is the chief vehicle of typhoid infection, and this knowledge has enabled great cities to make measurably effective defense against typhoid fever. For more than twenty years it has been known that the whole problem of preventing typhoid fever lay in the disposal of typhoid dejecta. Knowing so much, it would seem that typhoid fever might have long since been reduced to insignificance as a cause of death. But the bad eminence of the disease is as conspicuous to-day as it was twenty years ago.

In the grewsome story of typhoid among the United States troops during the Spanish-American War, we were confronted by a fact so humiliating that the profession has not yet had courage to consider fully its great significance. We learned that of every one hundred cases of typhoid fever sent to division hospitals, one-half had escaped the diagnosis of regimental surgeons. This enormous defect of professional skill was exposed, not by typhoid in its rarer and more subtle disguises, nor by the very mild infections, but by plain, uncomplicated typhoid fever, which puts a man to bed for three to six weeks; such typhoid as all physicians see year after year and recognize five or six times in ten. Restrictive measures can avail us little if the enemy can maintain effective disguise while fully armed and accoutred. The failure of definite and effective means to restrict the prevalence of typhoid fever is chargeable primarily against American medical schools, which do not teach young men to recognize the commonest continued fever of the United States.

Before the fight against typhoid fever can become hopeful one barrier must be leveled: a ponderous inertia which American medical education has imposed on the medical mind in respect to one disease. Until we are relieved of the dead weight of authority, the thraldom of the text-book, we shall go on misinterpreting, in 40 per cent. of instances, the clinical phenomena of typhoid infection. While dogmatic teaching is rapidly giving way to natural methods of study, there is in the portfolio of many a professor of medicine one lecture, or a set of lectures, which will be given up with great reluctance. The subject is typhoid fever, and the vivid descriptions so impress the students that they ever after require each case of typhoid to be as good as the description, to wear all its insignia, and to proclaim aloud its full name with decorations and titles. The prophylaxis of typhoid fever would gain an impetus from the conflagration of all such literature. Typhoid fever is taught too much; it is studied far too little. This defect of medical education has no preferred habitat within the confines of America. The glaring delinquency of Army medical men owed little to the latitudes in which it was demonstrated. These observers came from all parts of the land, and brought with them such light as their previous training and professional associations afforded. The men who entered the Army medical service in the late war were not more delinquent than those who remained in civil practice. There is a broad humor in Carroll's story of a solitary regimental surgeon who had no malaria among his fifty fever patients. He had a foreign accent, and had not acquired the American delusion that malaria is a considerable contributor to the mortality of the country.

In 1898 the Special Commission on Typhoid in the United States Army Encampments testified that no fatal malarial infections occurred to the soldiers in any part of the United States. In 1900 the profession of this country testified through the Census Bureau that for every seven persons who died of typhoid fever, three others died of malaria. In the south Mississippi belt the testimony is that twice as many deaths occurred from malaria as from typhoid. Among the twenty-one geographical divisions* of the country this one, the south Mississippi belt, showed the largest error in numbers, but a worse error was that of the central Appalachian region, where malaria is not even a considerable cause of disability, but where, nevertheless, it was charged with one death for every ten charged to typhoid.

I have plotted for each of the twenty-one grand groups the mortality returns of both typhoid and malaria by

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

* These Grand Groups do not respect state boundaries, but physical characteristics, as may be understood from their designations as follows:

| | |
|---|---|
| Grand Group 1. | North Atlantic Coast Region. |
| Grand Group 2. | Middle Atlantic Coast Region. |
| Grand Group 3. | South Atlantic Coast Region. |
| Grand Group 4. | Gulf Coast Region. |
| Grand Group 5. | Northern Hills and Plateaus. |
| Grand Group 6. | Central Appalachian Region. |
| Grand Group 7. | The Great Northern Lakes. |
| Grand Group 8. | Interior Plateau. |
| Grand Group 9. | South Central Appalachian Region. |
| Grand Group 10. | Ohio River Belt. |
| Grand Group 11. | South Interior Plateau. |
| Grand Group 12. | South Mississippi River Belt. |
| Grand Group 13. | North Mississippi River Belt. |
| Grand Group 14. | Southwest Central Region. |
| Grand Group 15. | Central Plains and Prairies. |
| Grand Group 16. | The Prairie Region. |
| Grand Group 17. | Missouri River Belt. |
| Grand Group 18. | Western Plains. |
| Grand Group 19. | Heavily Timbered Region of the Northwest. |
| Grand Group 20. | Cordilleran Region. |
| Grand Group 21. | Pacific Coast Region. |

having 88.9 per cent. of its total population rural, and a typhoid mortality of 79 per 100,000; south Atlantic division having a population 83 per cent. rural, and a typhoid mortality of 62 per 100,000; western division, population 68.8 per cent. rural, typhoid mortality of 33 per 100,000; north central division, population 59.4 per cent. rural, typhoid mortality of 42 per 100,000; north Atlantic division, population 41 per cent. rural, typhoid mortality of 30 per 100,000. Here we find the typhoid mortality rising as the urban population falls.

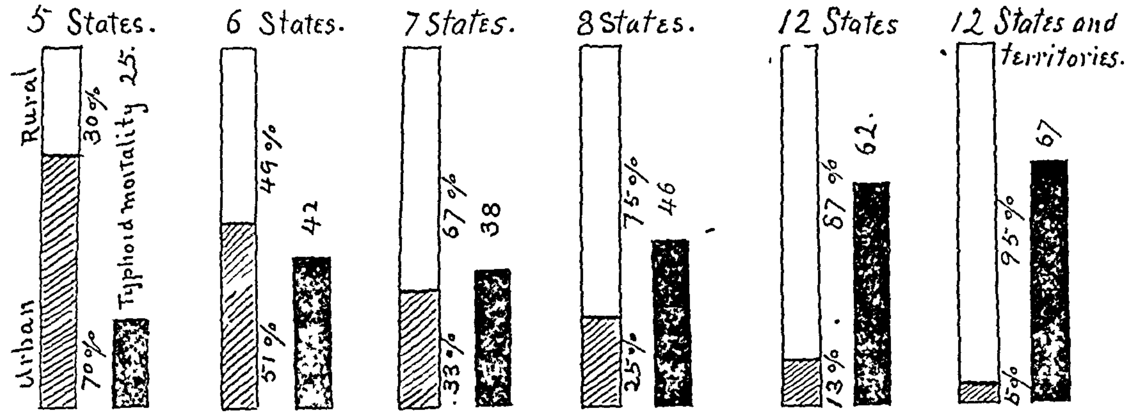

Chart 3. Showing typhoid increasing as we pass from urban to rural conditions. Rural populations indicated by white, urban by shaded areas. Black columns indicate typhoid mortality.

Some doubt may be admitted as to whether these grand divisions can fairly be compared. If the United States be divided into state groups on the basis of the distribution of population between town and country, we can eliminate to a great extent the influence of latitude and longitude.

Thus there are five states whose rural populations are under 30 per cent. of the totals. They are Massachusetts, New York, Rhode Island, New Jersey and the District of Columbia. Their aggregate population is 12,665,183, of which number 70 per cent. are classed as urban, i. e., live in towns of 8,000 or over. Their combined typhoid mortality is 25 per 100,000. (See Table I.)

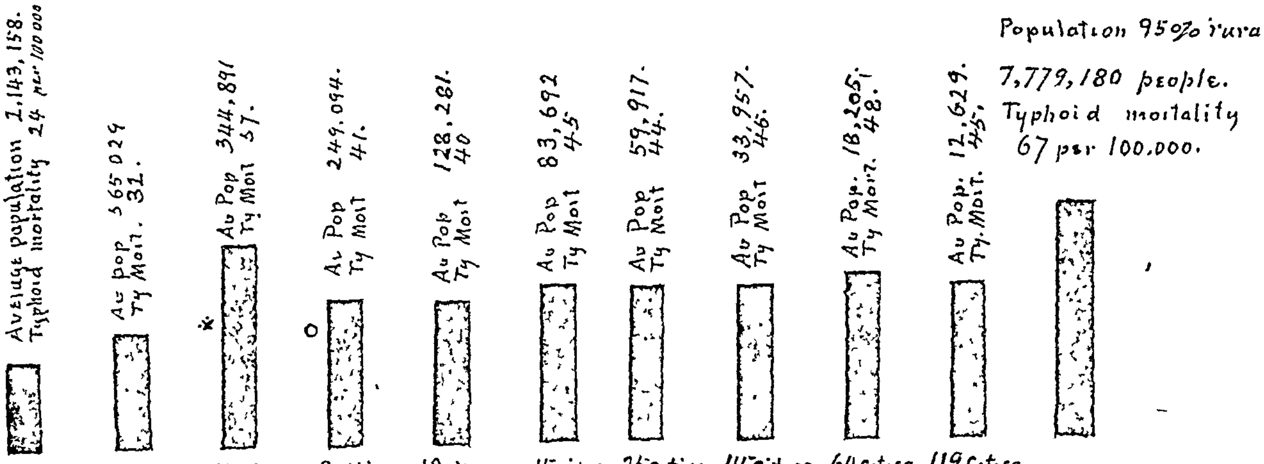

Chart 4. Typhoid in cities. Showing general inverse relation of typhoid to population.

* Includes Pittsburg with typhoid mortality 147 per 100,000.

○ Includes Washington with typhoid mortality 81 per 100,000.

Six states have populations between 40 and 50 per cent. rural—Connecticut, Pennsylvania, Delaware, Maryland, Illinois and California. In these the total population is 50 per cent. urban, and the typhoid mortality for 1900 was 42 per 100,000.

Seven states have populations between 50 and 60 per cent. rural—New Hampshire, Ohio, Michigan, Wisconsin, Missouri, Colorado, Washington. Their population is 43 per cent. urban, and their typhoid mortality in 1900 was 38 per 100,000.

Eight states have populations between 60 and 70 per cent. urban—Maine, Indiana, Minnesota, Louisiana, Montana, Wyoming, Utah, Oregon. Their population is 25 per cent. urban and their typhoid mortality in 1900 was 46 per 100,000.

Twelve states have populations between 70 and 80 per cent. rural—Vermont, Virginia, South Carolina, Georgia, Florida, Tennessee, Alabama, Texas. Their population is 13 per cent. urban, and their typhoid mortality in 1900 was 62 per 100,000.

Twelve states have populations more than 80 per cent. rural—West Virginia, North Carolina, North Dakota, Mississippi, Indian Territory, Oklahoma, Arkansas, New Mexico, Arizona, Nevada, Idaho. Their population is 5 per cent. urban, and their typhoid mortality in 1900 was 67 per 100,000. Taking the twenty-one grand groups into which the country is divided on a basis of physiography, and arranging them according to their population density, one finds that the typhoid mortality rises as population density decreases, until we reach a population density of 50 persons per square mile. Below that point the relations of typhoid to population density are, as might be expected, quite irregular. (See Table II.)

The experience of Maryland supports the general indications of these figures. There is but one large city in the state. The inhabitants of Baltimore are half of the total population of the state. There are but two other towns having as many as 8,000 inhabitants. It may be fairly said that the population of the state is equally divided between rural and urban conditions. The ratio of typhoid mortality is 1 to 2.5 in favor of Baltimore, a poorly-sewered city; supplied with unfiltered water from an extensive and unprotected water-shed.

Dividing the cities of this country into ten classes on a descending population scale, we find that the typhoid mortality rises somewhat as populations diminish. Thus the least mortality in 1900 (24 per 100,000) fell on the three cities having populations of more than 1,000,000—New York, Chicago and Philadelphia. Not one of these cities is watered or sewered in a thoroughly modern way. Indeed, one of them is notoriously bad in respect to water supply.

There are but three cities in the half-million class—Boston, Baltimore and St. Louis—whose combined mortality for 1900 was 32 per 100,000.

Next we have five cities—Cleveland, Buffalo, San Francisco, Cincinnati and Pittsburg—whose average population is 344,891, and whose combined typhoid mortality for 1900 was 57. In this group we have the banner city of the year in respect to typhoid mortality among populations of over 100,000, Pittsburg, with the large rate of 147 per 100,000. The combined mortality in this class, if Pittsburg were omitted, would be 37 per 100,000.

Next are eight cities with an average population of 249,094, and a typhoid mortality for 1900 of 41 per 100,000. The city of Washington, in this class, had a mortality of 81 per 100,000, adding 6 points to the combined mortality of the class.

In the next class are eighteen cities whose average population is 128,281, and whose typhoid mortality in 1900 was 40 per 100,000. The second city of the country in typhoid mortality among populations of over 100,000 is in this class, Allegheny, Pa.

In the next class are fifteen cities with populations averaging 83,692, and typhoid mortality for 1900 was 45 per 100,000.

Twenty-five cities whose populations averaged 59,517 had a typhoid mortality in 1900 of 44 per 100,000. The heaviest individual rate of the year in populations over 50,000 fell in this class on Savannah; 107 deaths among her 54,000 citizens, a rate of 197 per 100,000.

In the next class are sixty cities having an average population of 18,205, whose combined typhoid mortality for 1900 was 48 per 100,000.

Finally there are 119 cities whose populations average 12,629, and whose combined typhoid mortality for the year was 45 per 100,000.

Of twenty-four towns having typhoid mortality rates above 100, the tenth class furnishes eleven in the states of Connecticut, Iowa, Indiana, Louisiana, Wisconsin, Michigan, Kansas and Illinois. (See Table IV.)

The ninth class furnishes five towns, in Kentucky one, in New York two, in Mississippi one, in Ohio one.

The eighth class furnishes four towns, in Pennsylvania two, in Ohio one and in Colorado one.

The seventh class furnishes two towns, one in South Carolina and one in Georgia.

The sixth class furnishes one city, Atlanta, Ga., eighteenth in order of typhoid rate descending.

The third class furnishes one city, Pittsburg, Pa., sixth in rank of typhoid mortality descending.

The states contributing the eight highest urban rates are, in order, Georgia, Louisiana, Connecticut, Kentucky, Iowa, Pennsylvania, New York. Pennsylvania has two cities in this list.

In the list of cities showing rates above 100, Ohio has three towns; Pennsylvania, two; Connecticut, two; Iowa, two; Illinois, two; Georgia, two; New York, two; Louisiana, one; South Carolina, one; Kentucky, one; Indiana, one; Wisconsin, one; Kansas, one; Mississippi, one; Colorado, one; Michigan, one. (See Tables III and IV.)

The total population accounted for in this analysis of typhoid mortality is 20,922,886. The actual increase of typhoid mortality as the scale of population falls is probably greater than these tables indicate, for the states whose general mortality from typhoid is comparatively low are the chief contributors to the ninth and tenth classes, whose rates are highest.

The foregoing studies seem to warrant two conclusions, each having an important bearing on the general prophylaxis of typhoid fever. The first and more important is that the typhoid mortality reported in this country is not more (probably less) than 65 per cent. of the typhoid mortality actually occurring. Of the total morbidity from the disease a considerable part runs its course to recovery without coming under medical observation, and of the cases receiving professional care fully one-half are not recognized as typhoid fever. It therefore follows that the first step in the restriction of typhoid fever must fail for lack of diagnostic skill in the rank and file of the medical profession. The correction of this delinquency does not wait on improved methods of clinical or laboratory diagnosis, but on a general realization of the ubiquity and perennial activity of typhoid fever, and on the lumbering advance of reform in medical education.

A subsidiary conclusion from this part of the present study is that a very large majority of the deaths attributed to malaria are due to causes in which malaria does not even participate.

The second important conclusion, drawn from a study of the distribution of typhoid mortality, is that the infection is more heavily seeded in smaller communities, and that the propagation of the disease is in general from the country to the town, rather than from town to country. The explanation of this fact is probably found in the greater care given to the disposal of human excrement as communities grow more populous.

The prophylaxis of typhoid fever consists essentially in defense against excremental contamination, and precisely as the barriers are more or less remote from the sources of infection is the defense less or more effective. In this view of the prevention of typhoid fever it must appear that, notwithstanding the very great value of the defenses on which cities most rely, these defenses do not, and by their widest conceivable extension can not, satisfy the requirements of a rational prophylaxis of typhoid fever. In town and country alike the appointed time and place for intervention against the spread of typhoid fever is whenever and wherever a case of typhoid fever is recognized. Those outbreaks of typhoid which from time to time scandalize great cities and bring down wrath on the authorities are, as a rule, less important than, and may be part of, unremarked, unopposed, or perhaps lie-coddled epidemics covering the countryside for miles around. To set up at the city gates expensive works for the purification of the public water supply as a main defense against water-borne disease is literally a preposterous arrangement. It waives the choice of time, place and weapons, conceding all these advantages to the enemy. It assumes that the vices of rural insanitation are invincible, but they are not. If there is one direction in which, more than another, the political influence of great cities should be exerted, it is to bring rural districts and small communities under legal obligation to render strict account of deaths and the causes of death, and to take and give good heed to the preventable diseases at the time and place of their occurrence.

TABLE I.

FIVE STATES WHOSE URBAN POPULATIONS ARE 60 PER CENT. AND UPWARDS.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| Massachusetts | 2,805.346 | 2,132.023 | 625 |
| Rhode Island | 428.556 | 347.892 | 102 |
| New York | 7,268.894 | 4,980.042 | 1,776 |
| New Jersey | 1,883.669 | 1,153.001 | 398 |
| District of Columbia | 278,718 | 278,718 | 225 |
| | 12,665,183 | 8.892.276 | 3,126 |

Rural population, 30 per cent. Typhoid per 100,000, 25.

SIX STATES WHOSE URBAN POPULATIONS ARE BETWEEN 40 AND 60 PER CENT.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| Connecticut | 908,420 | 483.068 | 249 |
| Pennsylvania | 6,302.115 | 2,865.937 | 2,779 |
| Delaware | 184.735 | 76.508 | 90 |
| Maryland | 1.188.044 | 557.497 | 510 |
| Illinois | 4,821.550 | 2,271.940 | 1,807 |
| California | 1,485,053 | 649.474 | 542 |
| | 14.889.917 | 7.593.424 | 6,067 |

Rural population, 49 per cent. Typhoid per 100,000, 42.

SEVEN STATES WHOSE POPULATIONS ARE FROM 30 TO 40 PER CENT. URBAN.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| New Hampshire | 411.588 | 158.920 | 69 |
| Ohio | 4.157.545 | 1,599.840 | 1,795 |
| Michigan | 2.420.982 | 747.334 | 680 |
| Wisconsin | 2.069.042 | 634.437 | 365 |
| Missouri | 3,106.665 | 955.563 | 1,790 |
| Colorado | 539,700 | 205.703 | 222 |
| Washington | 518,103 | 165.282 | 171 |
| | 13,223.625 | 4.467.079 | 5,092 |

Rural population, 67 per cent. Typhoid per 100,000, 38.

EIGHT STATES WITH POPULATIONS 20 TO 30 PER CENT. URBAN.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| Maine | 694.466 | 164.639 | 200 |
| Indiana | 2,516.462 | 607.834 | 1,496 |
| Minnesota | 1,751.394 | 470.046 | 386 |
| Louisiana | 1,381.625 | 314.386 | 1,077 |
| Montana | 243.329 | 65.623 | 42 |
| Wyoming | 92.531 | 22.294 | 16 |
| Utah | 276.749 | 69.844 | 73 |
| Oregon | 413.536 | 98,807 | 106 |
| | 73,700,092 | 1,813.473 | 3,396 |

Rural population, 75 per cent. Typhoid per 100,000, 46.

TWELVE STATES WITH POPULATIONS FROM 10 TO 20 PER CENT. URBAN.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| Vermont | 343,641 | 305,054 | 107 |
| Virginia | 1,854,184 | 1,582.489 | 914 |
| South Carolina | 1,340,316 | 1,240.146 | 970 |
| Georgia | 2,216,331 | 1,972.562 | 1,585 |
| Florida | 528,542 | 449,413 | 290 |
| Iowa | 2,231,853 | 1,857,128 | 549 |
| Nebraska | 1,066,300 | 897,575 | 260 |
| Kansas | 1,470,495 | 1,265.288 | 688 |
| Kentucky | 2,147,174 | 1,784,115 | 1,669 |
| Tennessee | 2,020,216 | 1,750.298 | 1,709 |
| Alabama | 1,828,697 | 1,694,991 | 1,713 |
| Texas | 3,048,710 | 2,704,848 | 2,014 |
| | 20,096,459 | 17,503,907 | 12,468 |

Rural population, 87 per cent. Typhoid per 100,000, 62.

TWELVE STATES AND TERRITORIES HAVING POPULATIONS LESS THAN 10 PER CENT. URBAN.

| | Population. | Urban. | Typhoid. |
|---|---|---|---|
| West Virgnia | 958,800 | 885,197 | 586 |
| North Carolina | 1,893,810 | 1,797,273 | 1,250 |
| North Dakota | 319,146 | 309,548 | 65 |
| South Dakota | 401,750 | 391,484 | 73 |
| Mississippi | 1,581,270 | 1,510,176 | 1,370 |
| Indian Territory | 392,060 | 392,060 | 321 |
| Oklahoma | 398,331 | 378.288 | 201 |
| Arkansas | 1,311,564 | 1,240.201 | 1,172 |
| New Mexico | 195,310 | 195,310 | 102 |
| Arizona | 122,931 | 122.931 | 41 |
| Nevada | 42,335 | 42.335 | 12 |
| Idaho | 161,772 | 161,772 | 37 |
| | 7,779,179 | 7,426,575 | 5.230 |

Rural population, 95 per cent. Typhoid per 100,000, 67.

TABLE II.

THE 21 GRAND GROUPS, ACCORDING TO THE TWELFTH CENSUS, SHOWING POPULATIONS, TYPHOID-MALARIA VARIETIES, WITH DENSITIES AND TYPHOID RATES.

| Grand Group. | Typhoid Deaths. | Malaria Deaths. | Population. | Density. | Typhoid Mor'y. |
|---|---|---|---|---|---|
| 1. | 868 | 157 | 3,824.576 | 198.4 | 23 |
| 2. | 1,900 | 694 | 7,139.889 | 299.8 | 27 |
| 3. | 625 | 922 | 1,193.697 | 29.0 | 52 |
| 4. | 1,111 | 1,179 | 1,767.487 | 16.5 | 63 |
| 5. | 604 | 94 | 2,063.453 | 38.1 | 29 |
| 6. | 991 | 108 | 3,249.040 | 89.0 | 30 |
| 7. | 1,701 | 193 | 5,910.100 | 114.0 | 29 |
| 8. | 3.796 | 557 | 7,488.008 | 99.4 | 51 |
| 9. | 2,880 | 695 | 4.031,150 | 39.0 | 70 |
| 10. | 1.774 | 309 | 3.018,359 | 85.7 | 58 |
| 11. | 3,971 | 2,285 | 4.812.414 | 37.7 | 83 |
| 12. | 753 | 1,424 | 1,090.623 | 39.0 | 69 |
| 13. | 1,198 | 571 | 2,872.624 | 42.2 | 42 |
| 14. | 4,319 | 3,597 | 5,424.490 | 21.9 | 79 |
| 15. | 3.410 | 695 | 5,458.379 | 65.0 | 62 |
| 16. | 2,645 | 641 | 8,133.937 | 30.6 | 33 |
| 17. | 537 | 169 | 1,446.643 | 16.5 | 37 |
| 18. | 580 | 199 | 1,442.684 | 3.4 | 40 |
| 19. | 543 | 101 | 1,990.622 | 20.3 | 28 |
| 20. | 638 | 220 | 1,965.065 | 2.2 | 33 |
| 21. | 529 | 64 | 1,671,335 | 16.0 | 32 |

TABLE III.

*Three hundred and one American cities classified on a descending scale of populations; showing typhoid mortality according to U. S. Census figures for each of ten classes.*

CLASS I.

| | Population. | Deaths from Typhoid. |
|---|---|---|
| Chicago | 1,698,575 | 470 |
| New York | 3,437,202 | 594 |
| Philadelphia | 1,293,697 | 489 |
| Totals | 6,429,474 | 1,553 |

Average population, 2,143,158. Typhoid mortality per 100,000, 24.

CLASS II.

| | Population. | Deaths from Typhoid. |
|---|---|---|
| Boston | 560.892 | 153 |
| Baltimore | 508,957 | 177 |
| St. Louis | 575,238 | 190 |
| Totals | 1,695.087 | 520 |

Average population, 565,029. Typhoid mortality per 100,000, 32.

CLASS III.

| | Population. | Deaths from Typhoid. |
|---|---|---|
| Cleveland | 381,768 | 184 |
| Buffalo | 352,387 | 88 |
| San Francisco | 342,782 | 135 |
| Cincinnati | 325,902 | 106 |
| Pittsburg * | 321,616 | 474 |
| Totals | 1,724,455 | 987 |

Average population, 344,891. Typhoid mortality per 100,000, 57.

* Pittsburg being omitted, the typhoid mortality of the group is 37 per 100,000.

CLASS IV.—EIGHT CITIES.

| | Population. | Deaths *from Typhoid.* |
|---|---|---|
| *New Orleans* | 287,104 | 191 |
| *Detroit* | 285,704 | 54 |
| Milwaukee | 285,315 | 52 |
| Washington, *D. C.** | 278,718 | 225 |
| Newark, N. J | 246,070 | 26 |
| Jersey City | 206,433 | 46 |
| Louisville, Ky | 204,731 | *150* |
| Minneapolis | 202,718 | 83 |
| Totals | 1,996,793 | 827 |

*Average population, 249,094.* Typhoid mortality per 100,000, 41.

* Washington being omitted, the typhoid mortality of the group *is 35 per* 100,000.

CLASS V.—EIGHTEEN CITIES.

| | Population. | Deaths from Typhoid. |
|---|---|---|
| Providence | 174,597 | 52 |
| Indianapolis | 169,164 | 77 |
| Kansas City | 163,752 | 125 |
| Rochester | 162,608 | 38 |
| St. Paul | 162,065 | 36 |
| Denver | 133,859 | 57 |
| Toledo | 131,822 | 53 |
| Allegheny, Pa | 129,896 | 134 |
| Columbus, Ohio | 125,560 | 68 |
| *Worcester,* Mass | 118,421 | 21 |
| Syracuse, N. Y | 108,374 | 25 |
| Fall River | 104,863 | 23 |
| *Los Angeles* | 102,320 | 51 |
| New Haven | 108,027 | 33 |
| *Paterson,* N. J | 105,171 | 31 |
| St. Joseph, Mo | 102,979 | 37 |
| Scranton | 102,026 | 30 |
| Omaha | 102,555 | 41 |
| Totals | 2,309,059 | 932 |

Average population, 128,281. Typhoid per 100,000, 40.

CLASS VI.—FIFTEEN CITIES.

| | *Population.* | Deaths from Typhoid. |
|---|---|---|
| Albany | 91.151 | 41 |
| Richmond, Va | 85.050 | 66 |

| | Population. | Deaths from Typhoid. |
|---|---|---|
| Dayton, Ohio | 85.333 | 45 |
| Seattle | 80.671 | 31 |
| Atlanta, Ga | 89.872 | 98 |
| Lowell, Mass | 94.969 | 18 |
| Cambridge, Mass | 91.886 | 19 |
| Portland, Ore | 90.426 | 22 |
| Grand Rapids, Mich | 87.565 | 34 |
| Hartford, Conn | 79.850 | 45 |
| Reading, Pa | 78.961 | 35 |
| Wilmington, Del | 76.508 | 50 |
| Camden, N. J | 75.935 | 22 |
| Trenton, N. J | 73.307 | 25 |
| Bridgeport, Conn | 70.996 | 11 |
| Totals | 1.255.385 | 562 |

Average population, 83,692. Typhoid per 100.000, 45.

CLASS VII.—TWENTY-FIVE CITIES.

| | |
|---|---|
| Total population | 1,389,462 |
| Average population | 55,578 |
| Total typhoid deaths | 625 |
| Typhoid mortality per 100,000 | 45 |

| | Population. | Deaths from Typhoid. |

| Ironton, Ohio | 10 | 101 |

## DISCUSSION.

Dr. J. H. Musser, Philadelphia—It is fortunate that we can make an early, or more precise, diagnosis by modern bacteriologic methods, such as the *employment of the serum test*, or by culture methods; by such means we can make such precise diagnoses that there can hardly be any mistakes made regarding the nature of the prevailing fever or epidemic. There is no excuse, therefore, except probably in some communities or districts, for not making an early diagnosis. Unfortunately, however, there is a lack, apparently, of conscience *in physicians. They are not awake to the dangers of the infection in cases of typhoid fever.* Not long ago, within the last three years, I saw three cases of typhoid fever in one family in the country that had their origin as follows: The original case was an imported one. This man became infected in a near town and came to the country home of the physician, who was very careless regarding the disposal of the excreta. The relation of the privy was such that *its contents drained into a* driven well. This, of course, was the source of infection in the members of the family. One member of this family died and two were placed in great peril. These people were taken ill and all were sick, including the physician, due to the carelessness, or lack of conscience, on the part of the physician regarding the disposal of the excreta. There was a lack of re*gard for the protection of the people in that district.* I could tell of many local epidemics arising through the faults of physicians. It is, therefore, necessary to take a lesson to ourselves before we preach to communities. Communities should be educated in regard to this. Above all, the civil authorities should be brought to realize their responsibilities. In cities where there are piles of dirt, etc., a policeman goes and places a red lantern at each pile to indicate danger; yet no civic authorities would place a red light danger signal in places where there were epidemics or possibilities of typhoid fever. Why is this done in the first instance? Because the city knows that if an accident should happen the authorities would be held responsible. If we should hold the civic authorities similarly responsible in cases of typhoid fever we *could soon get control of the disease. How can we help our*selves regarding this? It is a difficult problem and a difficult question to answer.

It has been said that the busy practitioner has not time to act as police and see that his people carry out his directions regarding the disposal of excreta, etc. We should see developed a conscientious sense of duty which should inspire the untiring effort of all to protect communities as well as individuals. Each practitioner in a community should have a trained assistant. Let him take a man, for instance, from the Johns Hopkins Hospital Laboratory to assist him in laboratory work; any good practitioner can afford this. I am satisfied that any practitioner of medicine who takes an assistant to do work of this character, and so shows the community that he is *practicing the highest type of medicine and making every effort* to protect the community, will increase his income to twice what it would have been without an assistant in charge. If, however, that does not seem to be practical, then a group of physicians should have an assistant to make diagnoses and watch the excreta and to determine whether a typhoid fever patient should be sent forth in a community with safety by *examining* the urine, etc. If this is not practical, then we should resort to government control. We must educate the civic government itself regarding the danger of typhoid fever patients, and make them understand that they should be under their charge. The physician should continue to treat the patient, but *the civic authorities should be held responsible* for him until he is perfectly harmless. The patient should not be allowed away from a community. All the excreta and discharges should be taken care of. Then, too, perhaps, the government should be held responsible for the laboratory diagnosis and also for the sanitary management of the case, absolutely from the start of the infection. I do not think this is an unreasonable thing to expect. When we realize the trouble the government is taking with some infections, when we realize the mass of money that is spent to prevent the spread of yellow fever or the plague, when we think of how many more lives are lost through the ravages of typhoid fever, and when we think that our hands are practically paralyzed in our attempts to obtain governmental control of these cases, we must marvel at it. They should look after typhoid epidemics as they do after other epidemics.

I had hoped to learn a ready method for disinfecting the urine. Disinfection of the urine is very essential before the patients get from out of our control. Probably we can make the urine sterile by the use of urotropin. In the later stages of the disease and throughout the period of convalescence and until a trained assistant or a government expert shows the urine is free from bacilli these patients should not be lost sight of. The use of urotropin is one of the best methods for preventing as well as curing a complication of typhoid fever, i. e., cystitis; sterilizing the urine is the best aid in the way of prophylaxis.

Dr. DeLancey Rochester, Buffalo—Milk may be infected after leaving the farm, and the source of infection be difficult to trace. In Buffalo, in one of the healthiest districts, ten years ago, four members of the same family were taken ill with typhoid fever within four days of each other, and there was apparently no local reason for it. In looking for the source of the disease the milk supply was investigated. At the farm from which the milk came there was no typhoid. The milk was followed to the city, and the source of infection was found to be at the home of the man who delivered the milk. In his home was a case of typhoid fever; after he received the milk from the farm he had it bottled at his home, the same persons washing the bottles and caring for the typhoid patient. Thus it was accounted for. In his route through the city were found cases of typhoid fever.

In reference to the prevention of typhoid fever, we must remember that we do not know how long organisms persist in the stools after the patient has recovered from the attack. This is one chief source for the spread of the disease which should be borne in mind; after the patient recovers and goes about his business he still may be a source of infection on account of the persistence of the organisms in the stools.

I did not understand whether Dr. Fulton said that the disease was more prevalent in the country than in the cities, or whether the mortality was greater. If the latter, I think it is due to the lack of facilities, for the farmer will not or can not get the necessary nursing for these patients, and the consequence is that they die because they are not properly cared for; in such cases, of course, the physician is not at all at fault. I think the source of mortality in the country districts is to be found in this lack of proper care, or a lack of ability or willingness to care for these patients.

With regard to the disinfection of the urine, Dr. Musser has already referred to the use of urotropin. In three cases of typhoid fever we found the urine free from organisms and apparently in a sterile condition two weeks after the patient had recovered from the disease after giving urotropin; before that time the urine was infected.

With regard to disinfection of the stools, I have found that powdered chlorid of lime thoroughly mixed with each stool is efficacious.

Dr. Wm. Krauss, Memphis, Tenn.—We have a municipal ordinance which requires that every case of typhoid fever be reported, and in accordance with that requirement I reported a case. A lay inspector called and asked if the party had used well water or cistern water and got the address of the milk man. He left no literature or instructions as to the hygienic management of the case. The patient, a young lady, was very fond of ice cream, and would send to a nearby factory for a little paperboxful perhaps once or twice a day, and this was probably the source of infection. I think a municipal health board culpable for entrusting such matters to a policeman. The inspector should be a specially trained medical man.

About ten years ago I kept the records of the board of health in Memphis, and in one year I noticed that the returns for the year were about 270 deaths from malarial fever and 35 deaths from typhoid fever. This was before our public water supply was from artesian wells. Surely this was a wrong proportion of deaths from these two fevers, for in one season I had in my service at St. Joseph's Hospital about 400 cases of fever, in the neighborhood of 200 of which were malarial, of which latter only one died. Most of these patients were from the swamps about Memphis and were in a very bad condition. This would argue that many of the 270 deaths on the records must have been typhoid fever, since malarial fever with us is not so fatal.

Dr. Frank Warner, Columbus, Ohio—It is doubtless true that some cases of typhoid fever develop as a result of an infection acquired in some other way than drinking water; by eating some raw vegetables which have on them some typhoid bacilli, or by any of the several but unusual methods of acquiring the disease. It remains a fact, however, that the number of cases which develop in any other way than by drinking infected water are very few indeed. Then, as this is the usual method of infection, it becomes the duty of physicians everywhere to urge better water supplies in their respective communities. Not only does it become our duty to speak of these things, but also to point out from time to time that the great underlying cause of typhoid fever is the result of an absolute indifference in various communities of the dangers arising from drinking the water that is ordinarily furnished by many municipalities. There needs to be a rude awakening from the absolute indifference to which many communities have fallen. If the people in a community really make up their minds that there is a real danger in an unfiltered public water supply the politicians who operate the places will quickly install the most modern and approved methods of purifying water. They will give any community just as good water as they demand, and no better. It seems to me that it is time we should seek to prevent this disease on a greater scale than mere study and prevention of individual cases. This prevention on a large scale can best be accomplished by the construction of public filtered water supplies. And this filtered water is rendered purest by sand filtration. It is frequently argued against sand filtration that it does not remove all the bacteria of a disease-producing character. This is entirely true. It does remove some 98 or 99 per cent. of the pathogenic germs. Dr. William H. Welch has stated that one is not so likely to develop typhoid fever from drinking water which is only slightly infected with the typhoid germs as where it contains a large number of them. Then, if sand filtration does not remove all germs, and consequently all danger of infection, as it does remove at least 98 per cent. of the germs, it removes an equal per cent. of the danger of infecting the individual drinking the water. The ideal filter plant would remove all germs of a disease-producing character. Inasmuch as this can not be done, we must be content for the present to attain such a great improvement in the purity of a water in a community. And just in proportion that a pure water is furnished to a community, in just that proportion are we meeting the chief indication of prevention of typhoid fever.

Again, I believe that securing of a better water supply in any community should be a part of the labor of the physician and bacteriologist as well as the engineer. And this labor of the physician and bacteriologist should be as liberally paid for as the labor of the engineer. In seeking a water supply the engineer should be aided by the bacteriologist. This aid should not consist, as it does so many times when the engineeer calls such help, in simply examining the water for a time or two, but careful bacteriologic examinations should be made over a considerable period; these examinations should be made under varying conditions, so that a reliable conclusion may be drawn. While it is true that some of the more able sanitary engineers cover these points, still it is the rule that in the establishing of a public water supply the engineer regards it as distinctively an engineering problem rather than a joint undertaking of the engineer and the bacteriologist and physician. When this fact becomes better known and recognized we shall have purer water supplies and less typhoid fever.

Dr. J. N. Hurty, Indianapolis—It seems to me that the question of prophylaxis goes back further than we teach. At first we thought that, after the etiology of the disease had been discovered, all we had to do was to disinfect the dejecta. Now we find that there are clinicians and diagnosticians who do not make out all cases of typhoid fever. We all know that the dejecta carry the typhoid organisms long after the patients are seemingly well, months after in some cases. This fact should teach us something. We must not only disinfect the dejecta, but we must properly dispose of it; if that be done then we will soon abolish typhoid fever. I believe that all intestinal disorders, the germs of which are cultured in the intestines, will spread under certain conditions in the towns and large cities unless we treat and do away with the dejecta. We must filter the water in our towns and cities; and we must see that the dejecta are cared for in a sanitary way, then typhoid fever will certainly be abolished. I have read there was practically no sanitation in the days of Henry VIII, and that at that time the dejecta and slops were thrown into the streets; the proposition to care for them in pits was received with scorn and ridicule. But when the streets were used no longer for dejecta disposal there was a pronounced diminution in the number of cases of disease that arose from such causes; the death rate of typhoid fever and other diseases fell, and health conditions improved, after the human dejecta were cared for in pits. Let us go deeper into the study of this question and let us learn to care properly for all dejecta: then I can promise that the disease will disappear.

Dr. Henry Sewall, Denver—In the prophylaxis of tuberculosis it is admitted that physiologic resistance of the individual to the growth of tubercle bacilli is only second in importance to the exclusion of the bacilli themselves. In the prophylaxis of typhoid fever all sanitary effort seems to be restricted to the exclusion of the germ, and we hear nothing of the means of increasing the vital resistance of the individual after the manner which, in the conflict with tuberculosis, has proved so effective. The development of typhoid fever in a person is very largely determined by his physiologic condition while the typhoid germs lie in his intestines. A man recently under my charge had a mild run of fever for a few days; the Widal test was negative and the attack seemed clearly of "functional" nature. He was allowed to get up and increase his diet after some ten days, when shortly he became seriously ill, the blood test became positive and he nearly died with typhoid fever. Again, a little boy declared himself to have been perfectly well until he ran a foot race, when he was suddenly seized with vomiting and abdominal pain, ushering in a well-marked attack of typhoid fever. In each of these cases the attack of typhoid was exacerbated or precipitated as the result of physical exertion. A large proportion of our typhoid patients come from the hardiest and healthiest class of people. But they fall victims to the disease while engaged in work which upsets their physiologic equilibrium. They are very apt to be compelled to work to fatigue in the intense heat of the sun. It is not hard to imagine that under such conditions the germicidal powers of the gastric juice might deteriorate and the vital resistance of the body fluids and tissues themselves might be reduced. We might, therefore, speak of every individual enjoying, as regards typhoid fever, a certain immunity on a sliding scale. With every physiologic function doing well its co-ordinated task, the typhoid germ may possibly be ingested with impunity; immunity is high.' But let the vital machinery falter ever so little and infection readily occurs; immunity is low.

Dr. Deering J. Roberts, Nashville, Tenn.—Medical science is based on fact and on proof. Theories in medicine arise, spring up, live or die, depending on that idea. You can not build theories and make facts to fit them. Dr. Happel gave you the results of his observations; our work here is the result of observations. He records his observations of facts in his locality. On the other hand, representatives of Johns Hopkins and the University of Pennsylvania tell what they do not see. The microscope will tell you a fact and give the clinician aid when sustained by clinical observations. These men come with statements; Dr. Happel comes with observations. Take the humblest court in the land and submit to the bench two or three credible witnesses and you will be able to establish an observation as a fact. There is one witness from Arkansas. Dr. Witherspoon of Tennessee tells you what he saw. I claim to have seen the same fever for forty years. The Surgeon-General of the United States saw in the Army reports during the sixties something that was not down in the text-books, and he essayed to find out about it, only he went a little bit further and gave it a name. His efforts were sterile, so much so that he took back what he said regarding this fever and said he did not say it. Typhoid-malarial fever belongs to the ages of the past. One gentleman came here and endeavored to prove by therapeutic demonstration that we had a typho-malarial fever, "this and nothing more." You must look at things as they are and not as you wish to have them. I have seen 40 consecutive cases of fever in one season. Five years ago, before the Tennessee State Medical Society, I gave the clinical notes of a fever, "this and nothing more." This was not enteric fever. It ran along and gave an erratic temperature. Some have called it paratyphoid and atypical typhoid, etc. A leopard may change its spots, but still it is a leopard. There are certain characteristics about it which you can always recognize. What constitutes typhoid fever? The bacillus of Eberth must be present. Let the gentlemen with their monoculars and binoculars say what they please; we have the same in the laboratories in Tennessee. We have a series of recorded cases reported and published in the state medical society's transactions, with carefully trained observers, teachers in laboratory work, and in this series of cases the bacillus of Eberth was wanting. We have had it stated by able clinicians that this is a fever with erratic temperatures; that it was not attended by the abdominal symptoms of typhoid fever. I have seen 40 cases lasting 14 days or less, all of the same type. There have been reported 90 successive cases and none went beyond two weeks' duration. This is nothing but fever; let it alone and the patient will get well.

Dr. C. F. Adams, Trenton, N. J.—We have flies and mosquitoes in New Jersey; the mosquitoes are growing less, so is malaria. The Delaware river is a large sewer, and those who live along its banks become infected with typhoid fever. We make our differential diagnosis by taking a drop of blood on a slide for the Widal reaction, and also smear a cover slip for the plasmodium, and mail them to the state laboratory, where they are examined free. We should like to have the government prohibit the use of unfiltered Delaware River water for drinking purposes.

Dr. James Tyson, Philadelphia—I have been surprised that no reference has been made to the easiest and simplest way of making drinking water innocuous, i. e., by boiling. In Philadelphia to-day our hospitals are filled with typhoid fever cases largely to the exclusion of others, and I am sure that very few of these need have had typhoid fever if the drinking water had been boiled. Of course, we must look back to the source of infection. There are times when no filtration will protect the water against the typhoid bacillus; in fact, I believe that it is considered impossible to eliminate entirely the bacillus even when we have the best filtration plants; especially in times of great freshets, when there is a blocking up of the apparatus. If the working people could be taught to use no drinking water that had not been boiled many epidemics would be averted. Of course, the difficulty of doing this is evident, but we as physicians could do much by insisting on this practice, not only among the poor, but among the rich as well, and with all with whom we come in contact. The Schuylkill river water has not a good reputation, but I know of no instance where the disease has been acquired through the use of this drinking water after it was boiled. Boiling will effectually destroy the typhoid bacillus.

Dr. James J. Walsh, New York—A prominent sanitary officer once said that when somebody had typhoid fever somebody ought to be hung. We know that we can contract typhoid fever only from a typhoid fever patient. If that typhoid fever patient is not properly cared for somebody is to be blamed for criminal negligence. In large cities what is to be done?

Take a certain large city, not far from New York, which has had typhoid fever constantly in its midst for the past ten years. Every year there are a large number of deaths and the "boss" of that city has made the boast that he kept back the sanitary plant for a long time because provision had not been made for giving a part of the work to a friend of his. In this city there have been 3,000 deaths during that time from typhoid fever and nothing has been done toward getting a better and purer water supply. This boss has no sense of civic duty. Sanitary plants have been used in Germany for years; in Berlin proper filtration plants had been used thirty years before they had a death from typhoid fever. People on the farms have less death rate than in the city.

With regard to filtration, the little town of Altoona, near Hamburg, did not have a single death from cholera in spite of the fact that they used the water from the Elba. When this disease is communicated to another some one is criminally responsible. We should make the municipal authorities understand that the dangers lie in allowing certain tyrants to continue in control in sanitary work when there is a prolonged outbreak of typhoid fever.

DR. WALTER SHROPSHIRE, Yoakum, Texas—I am surprised at Dr. Tyson's statement that his patients might have avoided typhoid fever by boiling their drinking water, suggesting water as the only means of conveying the disease. In the town where I live, with a population of 6,000, there are 50 or more cases of typhoid fever each year. These people without exception use water from an artesian well, 1,400 feet deep, which is pumped direct into the mains and is never exposed to the atmosphere till drawn from the hydrant for drinking. If these people get typhoid fever through their drinking water I am unable to see how the bacilli get into it. Two years ago there was a case of typhoid fever near me treated by one who did not have the dejecta properly cared for, permitting it to be thrown out on the ground surface, this being in early summer when the ground was dry and dusty. Immediately following this case I treated 15 others within a radius of 300 yards of it, whose infection was traceable to this focus, and they could not have obtained the poison through water, for it was drawn from the hydrant and used immediately. I recall an experience of 12 years ago, when I treated a case of typhoid in December, and was unable to have any disinfectant used at all. The nurse simply threw the dejecta out in the back yard. During the balance of December, January, February, March and April we had no typhoid fever in that neighborhood. During May we had a drouth and the surface became dry and dust was prevalent, being carried by a prevailing southeast wind. The dry weather had existed not more than two weeks when typhoid began developing around this focus, and I treated 73 cases within a radius of 300 yards of it; and seven-tenths of them were to the northwest where the prevailing wind carried the dust from this infected focus. These people all used different water from surface wells about 70 feet deep and through a heavy clay and light rock strata. Now, if these people were infected through their drinking water why were there no cases through the five rainy months, when the earth surface was wet and why such preponderance of cases to the northwest where the prevailing wind would carry the dust from this infected focus? And if it be conceded that the spores were carried in dust by the wind and infected their drinking water, why could it not as well infect articles of food and thus reach the intestines of the individual? I am convinced that the dust was the means of infection in these cases as well as in many others. Again, our Spanish-American war demonstrated conclusively that flies can and do carry the infection, and Dr. Alice Hamilton of Chicago read a paper before this Association a year ago forcibly portraying the fact that flies do carry the infection. With such facts before us I think even Dr. Tyson should modify his remarks on the subject.

DR. T. J. HAPPEL, Trenton, Tenn.—The discussion of this morning has been on typhoid fever, not on the paper read by me on Tuesday.* The object of my paper was not to discuss the subject of typhoid fever, but to report cases of a fever occurring in my practice, which were cases of neither a typhoid nor a malarial fever.

I do not claim that there is no typhoid fever in the section of Tennessee in which I live, but in my own town it has almost entirely disappeared. We have not had a case of it for years. We account for our peculiar exemption from the fact that all of our drinking water is filtered through a vast bed of sand underlying our town. Some geologist claims that we are located over what in ages past was a large body of water which has been replaced by sand, and through this sand of an unknown depth our water filters, rendering it almost perfectly pure. While in our immediate neighborhood we have no typhoid fever, yet in certain sections of our county typical cases of typhoid fever are found.

When the cases reported to me are referred to as "atypical," "paratyphoid," etc., you are begging the question. In reference to microscopic examinations in these cases, I stated that examinations had been made in 138 cases of this fever by persons who had the reputation of being skilled in the use of the microscope and in laboratory work. Thus my clinical observations were not left unsupported. One person discussing the paper suggested that the variations in temperature were due to the use of the coal-tar derivatives. The coal-tar products are never used by me except in those cases where I have failed to reduce the temperature by water and other febrifuges. In not one of the 100 cases which have come under my care has there been any tendency to hemorrhage. One member of the section referred to the fact that he had cured cases of this type by a certain routine medication, but my paper referred only incidentally to the subject of treatment. In the closing lines of the paper I mentioned the fact that I used guaiacol carbonate in treating these cases the last season. If cases of this type of fever are let alone and nursed well they recover without or in spite of medicine. One of my patients recovered who was given by her mother on one occasion a box of sardines and allowed to eat them all at one time. At another time this same child during the third week of her fever was fed enough biscuits to have surfeited a well person. Had this been a case of typhoid fever we would probably have had a funeral. I have treated two cases of this fever in pregnant females, one five months advanced, the other seven. Both miscarried, and on the day following the miscarriage the temperature in both cases fell to normal and never went above that point again. Both made uneventful recoveries, a very different result so far as my experience has gone with typhoid fever under similar circumstances.

I wish again to emphasize the fact that the cases reported by me did not present a single characteristic symptom of typhoid fever.

DR. JOHN S. FULTON, Baltimore—I regret that any one should have misinterpreted my demonstration of the higher mortality of typhoid in rural districts as a reflection on the rural physician's skill. I know nothing about the comparative case mortality as between town and country, and I assume that the higher absolute mortality in the rural districts means a correspondingly higher morbidity. No other conclusion can be drawn from the evidence. In treating cases of typhoid fever the city physician has, so far as I know, but a single advantage over his fellow in the country, and that advantage is in skilled nursing. The trained nurse may, perhaps, profit the case mortality by the 1 or 1.5 per cent., but in my opinion the chief profit of trained nursing lies in the control of morbidity.

I take occasion to say now what I did not say in my paper, that the trained nurse, proportionately to the numerical strength of her profession, opposes more effective barriers to the spread of typhoid than does the practicing physician. That may be construed as a criticism of the profession and may be added to the other criticism of a 48 per cent. default of professional skill in the diagnosis of typhoid.

I did not intend in my paper to touch the minutiæ of prophylaxis, but I am glad that the discussion brought out the very central problem of disinfecting stools. A disinfectant for fecal matter should be first effective, and after that must be cheap, rapid, safe and convenient. No agent yet proposed meets all these requirements or even a majority of them. I am inclined to regard quicklime or air-slaked lime as the most generally available disinfecting agent for typhoid excreta.

---

* See THE JOURNAL, July 11, 1903, pp. 82 to 96.

But above all things I want to impress the Association with the testimony of the profession itself, shown here in graphic form, and supporting, as I think, in the most convincing manner and for the whole United States, the testimony of the U. S. Army Commission that the medical men of the land habitually misinterpret the continued fevers of the United States. This is a definite and insistent challenge at the very threshold of the prophylaxis of these fevers. What will you do about it?

---

# SHALL WE OPERATE ON DEFORMED SEPTA IN CASES OF ATROPHIC RHINITIS?*

KATE W. BALDWIN, M.D.
PHILADELPHIA.

Much has been written about this very greatly afflicted class of patients, and little has been accomplished. They should receive our best care for their own good and for the relief of the people with whom they come in contact. True, our horizon is the limit of our vision. The atrophic patient does not know the pleasure derived through the sense of smell; at the same time he does not appreciate the disgusting foul smell which makes him an undesirable member of society. The ancient Greeks considered ozena a good and sufficient cause for divorce. It was also considered a bar to the priesthood. Surely we may well advise against transmission to future generations.

Where a patient is convinced that he is an offense wherever he goes much has been done to gain the necessary perseverance in treatment. With eternal vigilance on the part of both physician and patient, results may be accomplished—a percentage of cures and the abolition of foul odors. The knowledge that we are shunned because of some avoidable defect in ourselves is about the greatest stimulus that can influence us.

Sclerosis or atrophy, without crusts or excessive secretion, due to overwork and pressure, is more advanced on the roomy side and in the inferior turbinals, the middle turbinals often being hypertrophied. Pressure on the tissues and an effort to perform normal function constantly irritate the narrow side, while the overwork and too free passage of air irritate the roomy side. Deflected septa plus spurs and ridges with enlarged pharyngeal tonsils are the local causes which lead to this condition. If this class of cases only is considered I am inclined to agree with the writers who claim that atrophy is a purely local condition, not dependent on other diseased conditions. I also believe that it is readily and quickly cured or much improved by the removal of the pharyngeal tonsil and by equalizing as nearly as possible the nasal space by correcting the deflected septum and removing ridges and spurs.

Add to the above local conditions a depraved constitutional inheritance and there results the class of cases generally recognized as atrophy. With the great loss of tissue, particularly turbinal tissues, all of which are involved, a very different picture is presented—marked ozena of a musty character, excessive secretion and crusts, with usually complete loss of smell. There is frequently a large lingual tonsil with little or no enlargement of the pharyngeal tonsil, a generally depraved constitutional condition, deranged stomach and bowels, irritable bladder, severe headaches, etc.

From careful observation and study of these cases I am convinced that heredity plays a very important—if not the most important—part in their production. Usually more than one member of a family is afflicted; and, if the inheritance is not direct from mother or father, investigation will trace it to uncles and aunts or to grandparents. One or more members of a family may have marked atrophy while others are subject only to frequent attacks of purulent rhinitis. In the absence of these local or constitutional causes repeated attacks of purulent rhinitis never develop atrophy.

The moderately enlarged pharyngeal tonsil is usually beneficial and many hesitate to remove it. In time past most operators have objected to correcting septal deformities for fear of added destruction of tissue in a space already too roomy, claiming that the spurs, ridges, etc., are a benefit. Perhaps they would be a benefit if they equalized the space and if they did not tend to the retention and difficult removal of the secretion. The retained secretion is a constant menace to the entire respiratory tract, accessory sinuses, and, in fact, to the whole system. The general and local conditions react on each other, and probably more depends on the local than on the constitutional treatment for the general improvement. At the same time, the better the general condition the more rapidly will the local condition respond to treatment. I have had several cases in which constitutional treatment had been given for years with little success in relieving the general condition; and local treatment alone relieved all the symptoms of stomach, bladder, etc.

Please do not understand me to advocate neglect of any of the cleansing, disinfecting and stimulating treatment which is so necessary in these cases and which must not be left entirely to the patient. The skilled physician can see and remove much secretion not within the reach of the patient. The more thorough the cleansing the more rapid will be the improvement. I do wish to urge securing the best possible local condition.

After a careful study of the cases and a few thorough cleansings, operate. Operate first on the sinuses of the roomy side if they are involved. As completely as possible correct the septal deflections, removing only the thickenings necessary to bring the septum into the median line. Later smooth up the septum as the individual case may demand. The tissues have not the recuperative power of normal nasal tissues, and much care must be used in the operation, not only to remove as little tissue as possible to gain the desired correction but to make no undue or unequal pressure, especially on the cartilages. Change the splint frequently and continue its use the shortest time possible. Never use a pin in an atrophic septum. A pin will often cause perforation in twenty-four hours and, once formed, the conditions are not favorable to its closure. Stimulate all cut edges to secure an over, rather than an under, inflammatory reaction. Excessive granulation tissue can easily be removed. With these precautions I am confident that operative interference will hasten the cure of atrophic cases.

The earlier in the course of the disease the operation is done the quicker and the better are results. I have yet to operate on a patient that does not see and admit benefit from the operation, as shown in the more rapid local and constitutional improvement and the greater ease with which the parts are cleansed. It is useless to cite cases, as all tell practically the same story. My private patients have possibly given the better results, as they have continued treatment a longer time and have been more thorough in their part of it.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

In the rare instances in which the process has run its course with complete destruction of the turbinal tissue and cessation of abnormal secretion and crusts it is probably wise to let well enough alone. I have seen not more than a half dozen such cases.

In going over more than 3,000 cases I find that deflected septa, with or without spurs and ridges, are almost invariably associated with loss of turbinal tissue; that in true atrophy it is the rule to find one fossa more roomy than the other and the atrophic process more advanced on the roomy side. The ages range from 3 years to 79. Occupation seems to have little influence in etiology, but good air hastens recovery as much as in any other condition. About 67 per cent. are women in my collection of cases. This percentage is doubtless too large, and means that women are more apt than men to seek relief when suffering from the condition.

Let me urge for the good of society at large the thorough treatment of atrophic cases and that the operative side be not neglected.

---

# THE DISTRIBUTION OF BLOOD VESSELS IN THE LABYRINTH OF THE EAR.*

GEORGE E. SHAMBAUGH, M.D.
Instructor in Anatomy of the Ear, Nose and Throat, University of Chicago; Associate in Otology, Rush Medical College.
CHICAGO.

The course of the blood stream through the labyrinth of the ear has been a subject of considerable uncertainty and difference of opinion among anatomists. The reasons are obvious, for the complicated series of cavities that go to make up the labyrinth of the ear makes the study of the blood supply by the ordinary method from sections very inaccurate, unless laborious methods of reconstruction are used. This element of difficulty was successfully overcome, however, when Eichler introduced the method of making celloidin casts of the labyrinth in which the circulation could be viewed in its entirety. But with this accomplished, and with such a complete picture of the blood supply before one, the complicated network of vessels found in the labyrinth of the adult ear is, in many places, very difficult if not quite impossible to disentangle with any degree of accuracy.

The arteries offer the chief difficulty, for in the fully-developed ear these vessels undergo a remarkable series of windings and convolutions which have been designated by Schwalbe as "glomeruli." It was found, however, that in the younger stages of the embryo the arteries are perfectly straight and simple, as are the veins. In this work the circulation in the labyrinth of the ear has been worked out, using the simpler scheme found in the younger embryos to interpret, when necessary, the more complicated system found in the adult.

The material used was the embryo pig. An unlimited supply of fresh material gave ample opportunity for experimenting with methods of injection until satisfactory preparations could be obtained in sufficient numbers for study. An aqueous solution of Prussian blue was used as injecting medium. This penetrates readily the capillaries, and with this fluid it is possible to get complete injection of the arteries, veins and capillaries. The differentiation between arteries, veins and capillaries in these preparations where but one injection was used, can be made out by carefully studying the preparations.

The method chiefly used in this work was that introduced by Oswald Eichler of making celloidin casts of the labyrinth from preparations that have been previously injected. Among the large series of preparations made were a few where the arterial tree alone was injected and several where the venous tree alone was filled. In most of the preparations both the arteries and the veins were filled as well as the capillaries. In addition to the celloidin casts, thick sections were made of the injected decalcified labyrinth in order to verify certain points about which there was an element of doubt from the study of the casts.

The results of the work can be expressed briefly as follows:

1. But one artery, the labyrinthine, supplies the labyrinth in the ear of the pig. This vessel enters the labyrinth along with the auditory nerve through the meatus acusticus internus. A single vein, the vena canaliculi cochleæ, drains the labyrinth, leaving, along with the canaliculus cochleæ, at a point distinct from that at which the artery enters.

2. The several divisions of the labyrinthine artery which go to supply the cochlea anastomose freely with each other through a number of anastomotic loops or arcades at the base of the cochlea, thus insuring for each part a blood supply reinforced freely from each division.

3. The arterial supply to the cochlea is arranged on such a plan that, as a rule, the vessels which send out the arteries to supply the scala vestibuli of a coil send out another set of arteries which supply the lamina spiralis of the coil next above. The arrangement usually described for the human ear, where the arteries for the scala vestibuli and for the lamina spiralis of the same coil comes from the same vessel, is found in the cochlea of the pig's ear, but only as the exception.

4. The venous blood of the cochlea drains entirely into the vena canaliculi cochleæ. The veins from the ligamentum spirale of the first half of the basal coil are collected into a large trunk which runs along the middle of the under surface of the basal coil to empty into the vena canaliculi cochleæ. The veins from the remainder of the basal coil are collected into the posterior spiral vein which runs along the posterior inner margin of the coil.

5. The venous blood from the upper coils of the cochlea is collected by a tributary of the posterior spiral vein. This vein in its beginning follows the spiral direction of the upper coil. It then passes directly downward through the modiolus to join the posterior spiral vein, receiving tributaries from the upper coils which converge toward this central vessel. The anterior spiral vein which Siebenmann found in the cochlea of the human ear does not exist in the ear of the pig.

6. The veins which lie between the coils of the cochlea are supplied by two sets of tributaries, one of which collects the blood from the scala vestibuli of the coil

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen. The detailed report of this research, from the Laboratory of Anatomy, University of Chicago, will appear with illustrations in the Decennial Publications of the University of Chicago.

beneath, and the other from the scala tympani of the coil above.

7. The so-called spiral veins of the cochlea, which are usually described running under the tunnel of corti, in the crista spiralis, in the crista of the ligamentum spirale and in the prominentia spiralis, are formed in the ear of the pig from capillary loops which form the boundary line for distinct capillary areas in these parts.

8. There was often found in the cochlea of the pig's ear a connection between the vessels of the lamina spiralis and those of the ligamentum spirale. This connecting link consisted of straight veins which ran from the terminal loops under the tunnel of Corti across to the veins in the crista of the ligamentum spirale, and were found in the terminal coil as well as in the basal coil.

9. The arterial supply for the vestibule and the semicircular canals comes in part from the anterior vestibular artery, and in part from arteries which spring from the anastomotic loops between the arterial trunks which supply the cochlea.

10. The venous blood from the vestibule and the semicircular canals is collected into two large trunks which empty into the vena canaliculi cochleæ. This is in striking contrast to the condition found by Siebenmann and Eichler in the human ear, where the veins from the semicircular canals left the labyrinth with the aqueductus vestibuli.

11. The capillaries are distributed almost exclusively to the membranous labyrinth. In the semicircular canals this is shown the most clearly. Here the capillaries surround the membranous canal while the vein runs along its inner concave surface, and the artery, for the most part, clings to the inner concave surface of the osseus canal, sending an occasional twig to the capillary loops around the membranous tube.

12. The capillary loops of the membranous semicircular canals do not, as a rule, completely surround this tube, but leave a zone along its convex surface free from vessels except for an occasional connecting loop which runs across this space.

## PROFESSIONAL RESPONSIBILITIES.*

A. E. BALDWIN, M.D., D.D.S., LL.B.

CHICAGO.

While this is a hackneyed subject, it is one on which we ought to devote a great deal of thought. We stand before the public and the general profession as the guardians of the entrance to the alimentary canal, and these responsibilities laid on us determine many things in connection with the general health of our patrons. I am not unmindful that while we occupy a very limited field as to the actual work which we do, the far-reaching effect of the work, or lack of it, is easily demonstrable. It seems to me that we fall short of a just and broad comprehension of our responsibilities in many instances.

These responsibilities begin in our advising our patrons as to the care and carefulness with which the temporary teeth of the little ones should be protected, as well as advising as to the care of the permanent teeth which obtain in later years.

In former papers before this and other gatherings I have urged on the general profession as well as on our special department the care which should be bestowed on the deciduous teeth. It doubtless is overlooked by many general practitioners and, judging from my observation, by even many in our special field that the teeth of the growing child should be kept more carefully even than the teeth of the adult. A reason apparent to all is that while in adult life nutrition is necessary only to make up for the waste of tissues, in the growing child there are many reasons why added nutrition should be obtained, chief among which may be mentioned the waste tissues which must be made up are fully as large in proportion as in the adult, while with the child there is a rapid development of the general system requiring much additional nutriment. Indirectly, there are many other reasons, among which are these: A child has a vigorous and almost unlimited appetite; if these deciduous molar teeth are allowed to become sensitive, painful or lost, the mastication of the child is necessarily hampered, and it is an axiom that a child will never masticate food if by so doing pain is caused. They very early in life learn that despicable habit of "bolting" their food with but little or no mastication, if mastication is in any way disagreeable, thus fixing on them a habit for life which is conducive to many of the ills of indigestion and malnutrition. A still further reason is the fact that all teeth in the mouth at all ages have a tendency to move toward the median line of the mouth, hence if one of these deciduous teeth is extracted before its successor is ready to erupt, the teeth behind will move toward the front, thus preventing the proper eruption and corresponding development and expansion of the arch, and causing the coming in of the teeth in abnormal positions, and creating irregularity and its subsequent ills.

I have always urged on the general profession and our special department that exceeding care should be given to the deciduous molar teeth, and that we should advise our patrons to urge on the child a thorough use of the brush. There should be frequent inspections of these teeth, and whenever a suspicion of decay invades them immediate professional attention should be given. If they are preserved in a healthful condition, mastication can be performed fully, so that the ills resulting from "bolting" of food may not invade the stomach of the little patient, bringing on it the ills of indigestion. We frequently recognize that in the case of a very nervous little one the only trouble, probably, is dyspepsia caused by lack of the above attentions, so that I would urge on the members of our specialty that most careful attention be given to these teeth until the time for them to be replaced by the permanent bicuspids, as well as that very great care should be observed in attention to the first permanent molar which is erupted at about the sixth year of age, and the molars which are subsequently erupted posteriorly thereto.

This first permanent molar we all recognize is the abutment of the arch, and is from its location, position, size and attachments, the most important tooth of the mouth to be preserved at this or any subsequent period. The loss of this tooth, or lack of attention thereto, as well as the lack of care of the deciduous molars, in my belief, produces most of these cases of irregularities and deformities of the lower part of the face, Nature having evidently intended that the lower part of the face should be developed and expansion thereto attained by the gradual wedging in and pushing apart of the alveolar process by the eruption of the larger teeth of the permanent set.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

I would also condemn a custom which may be illustrated by the following experience: A professional man of a neighboring city, whose record for general professional standing is high, had had a patient under his care for many years. The family recently removed to Chicago and this patient fell under my care, and on my calling his attention to many small cavities in the teeth he explained that his former attendant had said that he knew there were many small cavities, but that it would be better to wait and fill them later. This is to my mind one of the greatest fallacies and one which obtains more largely than is generally admitted. My belief is that whenever we have an opportunity to examine a patient's mouth we should give it a most rigid, careful and thorough inspection, calling the patient's attention to every defect which can be found by such a careful inspection and urging on him the importance of early attention thereto. Especially would I suggest that, if any teeth are left unattended to, they should be those which have large cavities; in other words, I would urge that the teeth attended to should be at least those which have the small cavities, thus preventing them from getting bad. It is a common expression of mine to such patients: "If for any reason you wish only two or three teeth filled and wish those to be the ones which need it the most, I will immediately, after careful inspection, fill the three teeth which have the smallest observable points of decay, thus preserving those teeth from becoming bad, and the very bad ones will only get a little worse." This will illustrate my position perhaps as well as could be otherwise expressed.

My observation has led me to believe that many members of our specialty do not recognize the importance of thus acting. In fact, my attention has been called by several men of prominence to the fact that by so doing one gets the name of being a high-priced dentist, and is thus marked for being shunned, when as a matter of fact such practice, while it causes much more work to be done at the time, saves a great amount of work in subsequent sittings of the same patient, as observed in a practice extending over a large number of years

I believe that we have large responsibilities also in careful observation of the relations which are borne by the teeth, their eruption, care, or lack of care, to the general health of the patient as well as reflex disturbances which may be brought about by this irritation being reflected and observed in other of the special organs of the head. Cases could be cited which would illustrate this, but I think that this matter is generally accepted as true by the profession at large, but sufficient care and thoroughness is not observed in a general way as to the minute observations of this rule in general practice.

Another responsibility which we face is that of supplying a masticating apparatus when the natural teeth and roots, or at least many of them, have been lost. Crowns and bridge work are, or may be, made most useful as a conserver or restorer of health when a lack of mastication has caused disordered digestion and the accompanying ills, and yet a note of warning should be sounded that bridge work or crowns may by improper adjustment be made to cause the very ills which they were intended to rectify. Very great care and thoughtfulness must be bestowed on bridge work and crowns to see that the articulation is made natural, and that the force of mastication may be on the lines of natural resistance which would have obtained had the natural teeth not been lost. I have seen many bridges which were absolutely useless in themselves, and which have caused the loss of many of the abutments thereto, thus making the last condition of the patient worse than the first. Our effort should always be to advise and recommend to our patients those things which we feel assured will be for the permanent welfare of the patient, never allowing ourselves to be misled by any suggestion or any wish of the patient to have cheap, or over-expensive, work done, if in our belief such work is unwarranted for permanent results.

Summarizing, I would urge early attention to deciduous molar teeth, great care and carefulness of the so-called six-year-old or first permanent molar, very thorough examinations of teeth always and early operation on any evidences of decay in any of the teeth at these or subsequent periods, and very great care observed as to recommendations of crowns or bridges, or any other artificial substitute, and a very careful observation as to reflex effects on other organs and tissues resulting from irritation in the mouth and teeth. These are a few of the many things which we should feel are responsibilities laid at our door for the protection and benefit of humanity at large.

34 Washington Street.

## DISCUSSION.

**MR. T. E. CONSTANT**, Scarborough, England—I agree with Dr. Baldwin on the necessity for the care of children's teeth. Dentists fully recognize its importance, but in England, and perhaps also in the United States, the majority of the members of the medical profession do not systematically examine the teeth of children under their care and, when it is necessary, recommend them to consult a dentist. If this were done many infantile troubles would be avoided, and by preserving the temporary teeth a great deal of work subsequently done by dentists in the way of regulation of permanent teeth would be rendered unnecessary. Many troubles are dependent on neglected conditions of the teeth in adults. When connected with a general hospital I had many opportunities of seeing incipient gastric ulcer. In almost all the cases the teeth were in very bad condition. In the prehemorrhagic stage of gastric ulcer, patients treated in the general hospital were relieved without any attention to the mouth, but with careful dieting, etc. It is the experience of physicians in England—I have not been able to demonstrate it—that careful repair of dental decay, removal of suppurating roots, and careful attention to the hygiene of the mouth have cured the patients without further medicinal treatment; and that, so long as the aseptic condition of the oral cavity was preserved by the patient after leaving the hospital, the gastritis has not recurred. It seems, perhaps, a bold thing to say, but, in my opinion, the majority of cases of severe gastritis in young women are due to defective oral hygiene. I therefore think the point in the paper is well taken.

**DR. T. L. GILMER**, Chicago—We do not get hold of children sufficiently early. As soon as the teeth have erupted we ought to see the children regularly for examination. We frequently have children brought to us with the teeth decayed to the extent of an uncovered pulp, and with a child of nervous temperament it is no wonder, under such circumstances, that extractions are made. I therefore insist that the children shall be brought to me, not only to examine for decay, but to see whether the caretaker in the home is giving proper attention to the dental organs and to the mouth. I believe I have in this way saved many more teeth by the prevention of decay than by filling. Prophylaxis, if intelligently carried out, will do a wonderful amount of good. It is the dentist's duty to examine not only the dental organs of his patients, both young and adult, coming for examination, but to scrutinize every part of the oral cavity. If we do otherwise we are unworthy the name of professional men. If the laryngologist examined only for one diseased condition he would hardly be considered a valuable man to his patients. Not long since, in examining the mouth of a patient, I discovered under the tongue a stone in Wharton's duct which had been overlooked. This calcareous deposit had caused a serious condition of the submaxillary *salivary gland.* The patient might have been spared this trouble had the family dentist kept close watch over all of the mouth, instead of only examining the dental organs.

**Dr. Eugene S. Talbot**, Chicago—If there is any one time in the life of the child when oral hygiene should be at its best, it is at the time of the eruption of the temporary teeth. In my studies on evolution it is noted that the face, the jaws and the teeth are changed from generation to generation. To a certain extent the nationality of an individual may be judged by the evolution of the head and face. I believe in these transitory structures the conditions in the mouth, decay of teeth, etc., are very apt to occur. It is at the time of the eruption of the temporary teeth we have what I have termed the second period of stress. These periods of stress are very much on the same order as people speak of the systemic changes every seven years. At this time the dentist has an idea that all diseases of the human body revolve around the teeth, and to a certain extent this is true; but he forgets that the mucous membrane throughout the body is undergoing a great change at the same time. Up to this the child has been taking liquid food, the system is now preparing itself for harder food, and the cells of the mucous membrane are undergoing a great change. Therefore, as the essayist has stated, the greatest care of the teeth should be taken at this time. I do not agree with Weissman regarding the non-inheritance of acquired defects. I do believe in the inheritance of acquired defects, and have proved the theory. In Mississippi, and I suppose in other parts of the South, and in England, the habit is to extract the first permanent molar, especially if it be decayed; in the South it is customary to extract it on general principles; the reason being that the extraction of this tooth allows the others to erupt in a normal condition. This particular point is important because of the transitory nature of the jaws. Continuous extraction has a tendency to produce arrest of development, the inheritance of acquired defects. It is, therefore, a cause of irregularities of the teeth as seen in England, which is further intensified from generation to generation.

**Dr. G. L. Curtis**, New York—I can verify from my own observations Mr. Constant's remarks in relation to diseases of the throat. I believe that a very large portion of the work done by specialists of the throat becomes necessary because of the pathologic condition of the teeth. Children should be taken to the dentist for examination and treatment early in life and often, at least every three months, and if the dentist finds disease of the throat he should direct the patient to the proper person for treatment. A specialist in diseases of the throat once met me in the street and said: "I shall soon have to send you a percentage of my income." I asked him why, and he replied, "Because you send me more patients than all the other dentists in the city put together." That remark stimulated me to a closer observation of the nose and throat of a patient, but I refused to accept any percentage. I think extraction of the six-year molar is generally a lazy man's way of avoiding work. I believe it should never be done except where the child's tooth is abscessed, and in many cases not then. There are, however, individual characteristics that may require special treatment.

**Dr. M. L. Rhein**, New York—The necessity, for men who assume the position of caring for the teeth, of realizing their responsibility, can not be too strongly urged. It is my invariable rule to pay absolutely no attention to the suggestions or directions of people coming to me until I have made a thorough examination. I then inform them of what I deem advisable to be done, and if it does not meet their wishes our relations end at that point. I believe that is the only truly professional line of conduct. This, I think, differentiates between what we are pleased to call stomatologists and dentists.

**Dr. W. E. Walker**, New Orleans—We do not always "see ourselves as others see us." I did not know that it was the practice of England and the South to sacrifice the first permanent molar. This extraction does occur here I am aware, but I judge from articles written on it that this is practiced elsewhere. Here I know it is too common. In regard to examining the whole mouth instead of looking simply at the tooth to which attention is directed by the patient, that this practice is not sufficiently common among dentists has been impressed on me by the surprise occasionally manifested by a patient when I have proceeded to examine the whole oral cavity rather than simply the tooth complained of.

**Dr. M. L. Rhein**—I agree with Dr. Walker that there is as much extraction of the first permanent molar in the East and West as in the South. There is no warrant for the removal of the first permanent molar.

**Dr. George F. Eames**, Boston—This subject should be brought to the attention of the general practitioner and of other specialists that patients may be advised in regard to oral conditions. It should also be brought to the attention of laymen. The subject of the relation of the local conditions in the mouth to the general health I consider of the greatest importance.

**Dr. A. E. Baldwin**—In a paper of this kind one can only touch on the different subjects. I would especially emphasize what Dr. Gilmer has said of not having opportunity to see patients sufficiently early. As Dr. Eames has said, there are relations to be recognized. Our object should be to unify all the departments of the healing art in one great whole.

---

# TOLERANCE OF THE TISSUES TO FOREIGN BODIES,

## WITH SPECIAL REFERENCE TO THE PULP AND GUMS.*

M. H. FLETCHER, M.D., D.D.S.
CINCINNATI.

The reason that one foreign substance within the tissues is more or less irritating than another, is to be determined not alone by the character of the substance but also by how it influences the cells of the tissues involved. That environment influences cell life is well known. Aside from the effect of their food, cells may be influenced by temperature, electrically, by chemicals and mechanically. Our present purpose is to consider mechanical irritants.

In treatises on gunshot wounds it is presumed that the bullet is of lead, and the practice almost universally advised is to leave the ball undisturbed if it is not easily found. There is an adage generally recognized to the effect that "when a bullet has ceased to move it has ceased to do harm." The accompanying specimens (Figs. 1 and 2) of elephant's tusks, No. 1 with a lead bullet encapsulated, No. 2 with an iron bullet rolling about in what seems to have been a pus cavity, shows the different effects these two metals may have on living tissue (assuming the conditions to have been the same). These bullets, which have been shot at the animal's head, have penetrated the pulp chamber of the tusk, the animal living long enough afterward for the bullet to become encapsulated in ivory (Fig. 1) or produce a pathologic cavity (Fig. 2).

The protrusion of a broken breach from the apex of the root of a pulpless tooth, seems invariably to cause an abscess, whereas the protrusion of a gutta percha point apparently causes no trouble. A number of years ago Gunn suggested the use of beeswax for packing wounds in place of other dressings and it is found to be a good procedure, the wax being unirritating to granular surfaces. Four years ago Gersuny of Vienna demonstrated the practibility of injecting even large quantities of paraffin and vaselin into the tissues for therapeutic as well as for prosthetic purposes.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

I have been using softened gutta percha as a therapeutic measure in bone cavities for a number of years. My attention was first drawn to this feature seventeen years ago by having inadvertently injected too much "chloropercha" (gutta percha dissolved in chloroform) through a pulpless tooth into a blind abscess. A tumor of this material the size of a pea could be felt at the apex of the tooth, and since it caused no inflammation and produced no trouble it was allowed to remain undisturbed; it is there to-day, and has never caused the least disturbance. I believe it is the practice of many dental surgeons to inject this dissolved material through pulpless teeth until it appears at the fistulous opening, expecting the tissues to heal quicker by this treatment than by any other (Fig. 3).

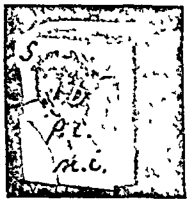

Fig 1

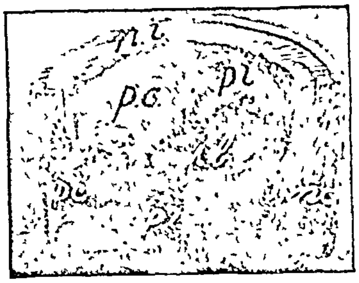

Fig. 2.

Fig. 1.—Block of ivory from elephant's tusk, with lead bullet completely encapsulated. n. i., normal ivory; p. i., pathologic ivory; l b, lead bullet; s, place where section shown in Figure 6 was taken.

Fig. 2.—Block of ivory from elephant's tusk, with iron bullet in pus cavity. n. i., normal ivory; p. i., pathologic ivory; p. c., pus cavity; i. b., iron bullet.

Caseous pus may become encapsulated and remain apparently harmless until finally absorbed.

Trichina in small numbers no doubt could remain indefinitely in the tissues without their presence being known, for they are most beautifully taken care of, as the accompanying picture shows (Fig. 4).

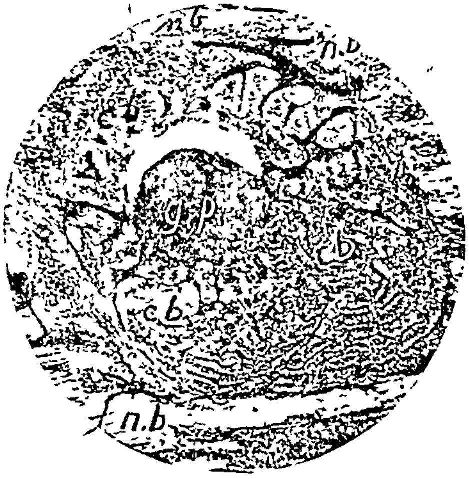

Fig. 3—Section of bone after recovery from implantation of a dog's tooth in a goat's jaw, ×10. g. p., encapsulated gutta-percha which had been placed in the root canal of the implanted tooth, n. b, normal bone; c. b., cicatricial bone.

Steel needles may wander through the flesh without pain and without apparent damage. Dr. P. S. Conner is authority for the statement that a knife blade may be tolerated in the same manner, and says that iron balls, fragments of shells, splinters, and, in fact, almost any foreign material, if not accompanied by septic matter, may become encapsulated, but also agrees that softer, more yielding substances, which are impervious to moisture, are less irritating.

We will assume then, that, as foreign bodies, certain substances are, *per se*, noxious or innoxious in degrees proportionate to their physical properties. Those that are most innoxious are impervious to moisture and more or less yielding in character. Hard smooth substances like a needle or knife blade may be tolerated, but if they become oxidized or roughened by chemical action they then seem to produce trouble. Hard rough substances of any kind seem more irritating than a soft pliable material, providing the latter be impervious to moisture; pieces of cloth or bits of wood seem especially noxious for reasons which may be explained.

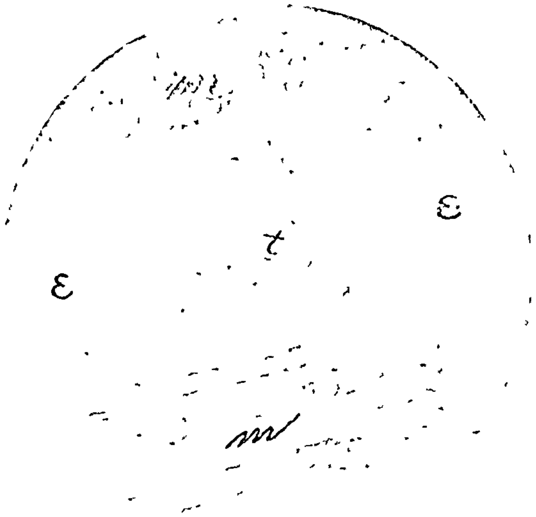

Fig. 4.—Trichina in muscle of a cat. ×50. t., trichina; m., muscular tissue; e., encapsulating material.

Foreign bodies may be classified as extrinsic or intrinsic, according to whether they are forced into the body from without, or whether they were part of the body, or produced within.

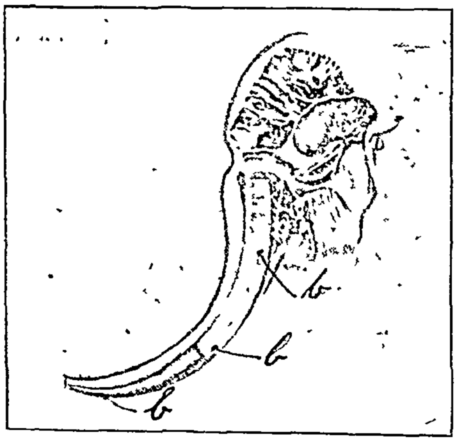

Fig. 5—Diagram from Owen; showing how a bullet lodged in the pulp chamber of a tusk is finally discharged near the point. b, bullet in different positions as the tusk grows longer.

Intrinsic foreign bodies may include dead tissue of any character, sequestra, pulpless teeth, calcareous or phosphatic deposits; these deposits when found about the necks of the teeth are always rough and irritating, and are so situated that bacteria have free access to the irritated tissues.

### THE PULP.

In teeth of persistent growth the pulp practically remains one size and is more or less cone-shaped, with its apex directed to the grinding surface and into the long axis of the tooth the base of the pulp is at the source of supply, as shown in the elephant's tusk (Fig. 5). When an injury occurs to such a pulp it has every chance of recovery that other tissues have, because of collateral circulation. If the irritant be an extrinsic body (as shown in the elephant's tusk) it is finally pushed beyond the zone of the pulp (Fig. 5) and the formation of dentin proceeds regularly as before (Fig. 6). This is true of all tusks and the incisors of all rodents.

In mature teeth of limited growth, as found in man, these conditions are reversed; the apex of the pulp is directed to the apex of the root and the blood and nerve supply is limited to the minimum amount necessary to the life of the pulp, so that in case of injury there is no collateral circulation or nerve supply for purposes of rapid repair, such as may be found in other tissues, hence the great number of pulpless teeth in human beings, where lesions of the pulp far outnumber those of any other animal.

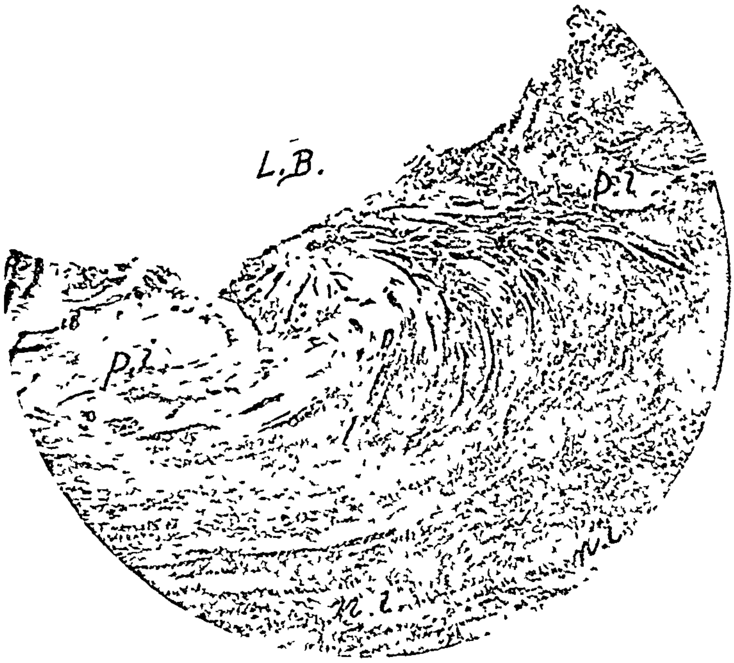

Fig 6—Section taken from specimen Figure 1 at place marked s n i, normal ivory; p. i., pathologic livery; l b., surface where lead bullet was in contact with the ivory. ×14

In filling teeth a pulp may be successfully capped with any suitable innoxious substance, providing the capping does not press the pulp. The walls in which this organ is confined being unyielding, any pressure beyond normal produces inflammation, which can not be taken care of as it could in other tissues; this is from lack of ability to expand, as is necessary in inflammation, hence the death of the pulp in a comparatively short time. An exposure of the human pulp or other injury to it, is most prone to its ultimate death, no matter how successfully the capping may have been done, and it would seem that this proneness to die is due to the very limited supply of vessels. Aside from the difference in mechanical surroundings, there seems no reason why this organ should not recover from injury as easily as any other composed of like tissues, for the process of repair here is no different from that of repair in other tissues of mesoblastic origin The fact seems to be that the process of repair is practically identical in all tissues, the great essential being abundant blood supply.

Decay, fillings, cappings or abrasions, may be looked on as extrinsic foreign bodies, they stimulate the pulp to action, resulting in an effort on the part of this organ to protect itself from an enemy or repair damage done

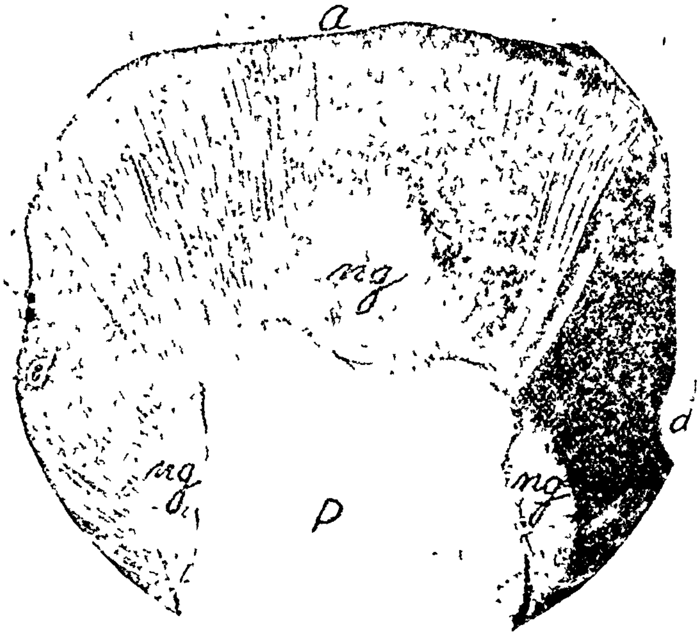

Fig 7—Section of deciduous canine ×14 p, pulp chamber, n g, new growth; d, decay, a, abraded surface

The peripheral ends of the dentinal fibrils may be considered as a part of the pulp, and any wearing away or destruction of any part of these delicate processes is a lesion of tissue as truly as an amputation or other larger injuries Irritation to the pulp, which is short of acute inflammation and death, usually results in the production of more dentin. This may take the form of nodules, or a protective growth at the pulp ends of the fibrils irritated. These growths are shown in the accompanying tooth sections (Figs 7 and 8). This effort at pro-

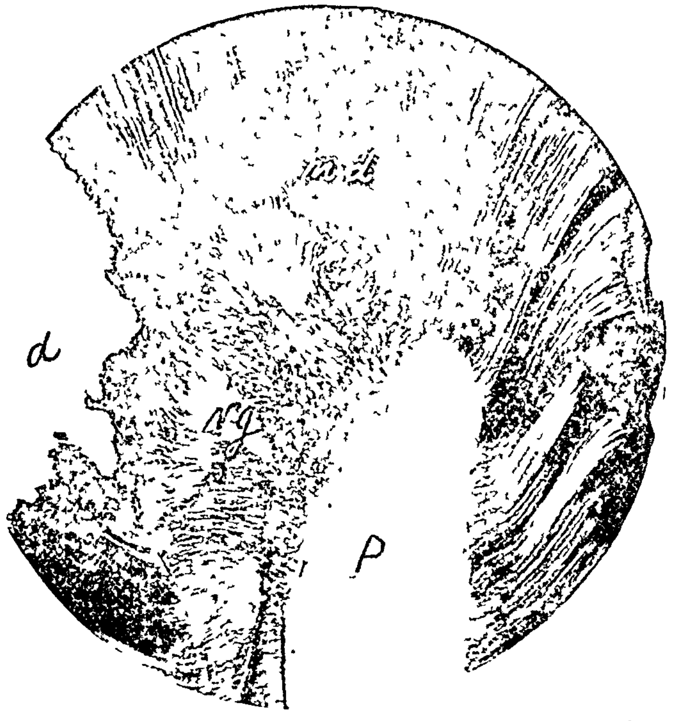

Fig 8—Section of permanent canine ×14 p, pulp chamber n g, new growth; n d, normal dentine; d, cavity of decay

tection, however, often results in death from lack of space in which to work, accompanied with the lack of collateral circulation. Compare these results with that of injury to the tusk. Repair in the latter case is not hindered by unyielding confinement and limited circulation as it is in the former, and restoration is complete. Pulp nodules, in many instances, act as foreign bodies, and end with a destructive result to the soft tissue involved. Adherent new growths, in the pulp chamber, also have similar endings in many cases; the attempt at repair itself defeating its own object.

Chas. B. Nancrede[1] says:

> Repair is effected by the same processes in the hard and soft, the vascular and the avascular tissues, the differences being temporary, non-essential and chiefly dependent on physical conditions. Thus, the lime salts render the bone so dense that until they are removed only a limited accumulation of leucocytes and, later, proliferated tissue cells, can take place at the site of injury; yet from the outset, the soft parts of the bone undergo the same changes, in kind, as does the least compact connective tissue. Two forms of repair are usually described, but in reality there is but one, the second variety being at the outset only a modification of the first, caused by disturbing influences; when these cease to be operative the processes of repair tend to proceed as at their inception, any variations from the typical methods being accidental, not essential parts of the process. In the normal method reparative processes commence from the moment the physical disturbance of the part ceases and the bleeding is checked. Here the minimum of reparative material is requisite, and the wound is said to heal by the first intention, by simple adhesion or by aseptic inflammation (obsolete expression), because it is only possible in the absence of infection. Where infection occurs the reparative processes are interfered with and thwarted. reverting eventually to those seen in the absence of suppuration, but vast quantities of reparative materials are wasted, unnecessary tissue destruction results, and the subsequent changes in the excessively developed germinal tissue often cause serious interference with function. Healing is here said to have taken place by granulation or by the second intention, but the end processes are the same in both forms.

When irritation goes beyond that of the mere stimulation of function this description of repair seems to cover every field, at least up to our present knowledge, and especially that of pyorrhea alveolaris.

### GUMS AND ALVEOLAR PROCESS.

In the discussion of interstitial gingivitis, so-called pyorrhea alveolaris, the process of repair, as above described; is the important factor, as it is in all lesions, the exciting cause having been determined.

The local destructive metabolism, in this disease, is identical with that of any like tissues. Where constant ineffectual efforts are being made to extrude or absorb noxious foreign bodies we have like results, namely, destruction of much of the surrounding tissues. In gingivitis the foreign body, in the incipiency of the disease, is nearly always calcareous deposits.

To Talbot more than to any one else is due our most intimate knowledge of this disease; his extended researches and observation of the disease in man and animals, and his experiments on dogs, bring the matter close under our observation. In his conclusions[2] he says:

> The mass of evidence previously presented demonstrates that the causes of interstitial gingivitis are divisible into predisposing causes (which may be subdivided into local predisposing and constitutional) and exciting causes. The exciting causes are either constitutional or local, but as a rule are local or have local action.
>
> The predisposing factors of this disease, as already mentioned, are: conditions of jaw evolution, transitory nature of certain structures, degeneracy and conditions of previous irritation and inflammation.

In his mercurialization of dogs for the study of the production of the disease by drugs (page 117) he says: "Care was taken to secure those in health and with healthy gums."

I should deem it a practical impossibility to know that there was absolutely no deposit about the teeth of these dogs and think it fair to assume that there must have been some deposits, however small; since domesticated dogs, like men, all have calcareous precipitations about the teeth to some degree, it may not be malignant in its tendency until the etiologic moment has arrived, the other factor being lessened resistance by other morbid systemic conditions.

Slight irritation from calcareous deposits may remain *statu quo* for years and finally a general morbid condition arrives, or rises to such a pitch that pyorrhea alveolaris or other advanced conditions of interstitial gingivitis are produced. The inflamed condition of the tissues about the teeth in interstitial gingivitis, it seems, is simply a continual effort at repair, which repair can not be accomplished on account of the presence of calcareous deposits, or the phagadenic progress of a pus cavity about the roots, the pyorrheal stage. Thus it happens in these cases, as in others, that Nature thwarts her own object in her attempt to accomplish it, and destroys much of the surrounding tissue.

My conception of interstitial gingivitis is that it is essentially local in its exciting cause, and that it only has systemic symptoms for the same reasons that other lesions may have auto-intoxication as one result. There seems no reason to believe that drug poisoning or other morbid systemic conditions can produce interstitial gingivitis without a lesion of the gum pre-exists; this lesion may be the merest break in the mucous membrane, caused by the smallest deposit of this irritating material, this local mechanical irritation being one requisite of the etiologic moment. On the other hand, there may frequently be found in gingivitis the systemic disorders accompanying cases of sapremia and septicemia.

The continual pressure against the gum tissues of rough irritating calcareous deposits, which continuously increase in quantity and insinuate themselves deeper and deeper beneath the soft tissue, are accompanied with all the products of repair by granulation, or second intention, as described by Nancrede, and may be accompanied with surgical fever. These deposits may be found wherever saliva can penetrate. It has never been my privilege to see deposits of tartar about the necks of the teeth that were innoxious, but they are always irritating to some degree, and usually greatly so. This condition may exist in all stages, from that of being imperceptible to the naked eye, up to a complete state of pyemia, and may result in death.

In one case which came under my observation death resulted. The culminating cause in this instance was no doubt due to the exposure of more bone by the extraction of a molar, while the gums and alveolar process were in the worst possible state. When the patient was presented, exfoliation was going on and much bone about the teeth was exposed, the patient having a high septic fever. The septic condition was recognized and advice given against extraction. The patient, however, was suffering greatly with a lower first molar and went elsewhere to have the tooth removed. I was called again later, but the patient was past recovery and died within ten days after the extraction.

---

[1] Roswell Park: Treatise on Surgery, p. 350.

[2] Interstitial Gingivitis, p. 148.

There is abundant evidence to show that auto-intoxication, or a low state of health from any cause, greatly favors the progress of the disease, and with this state of affairs present, a chronic pus-forming condition may soon be found about one or more of the teeth where the local exciting cause exists, but that autointoxication or other systemic disorders cause this disease, without local irritation, does not appeal to the writer's reason any more than to say that the same disorder causes inflammation of the pleura or conjunctiva without a local point of least resistance from local cause.

Degeneracy or faulty development may bring the etiologic moment at a very early stage of the local irritation. This might be almost coincident with the initial lesion, whereas in normal and healthy individuals the pyorrheal stage, even in its mildest form, may be deferred indefinitely, or never appear even where calcareous deposits are excessive.

The fact that the tissues involved are transitory in nature does not seem an adequate factor in accounting for the disease, as suggested by Talbot, since they are as transitory in cases where the disease does not exist as where it does, and these tissues recover as readily as other structures which are not transitory.

There seems no question but that calcareous deposits about the teeth should be looked on as noxious foreign bodies and that the constant effort on the part of the tissue to extrude them results in the progressive death of the surrounding tissue. We find in this disease zones of granulation tissue, with the result of destructive metabolism in the soft tissues and the creation of sequestra in the bone. This condition, however, is changed to constructive metabolism the moment the tartar, sequestra or other local irritants are removed.

### SEQUESTRA.

The removal of sequestra by Nature is described by Roswell Park as follows:

> A sequestrum may include an entire bone, shaft or ephiphysis, or only a small fragment. A given portion of the bone, having lost its vitality, becomes properly a foreign body which the surrounding tissues endeavor to extrude or to wall off and surround. The extrusive effort is the one which is usually seen. This is done by the continued presence of granulation tissue, which gradually perforates the surrounding bone at places of least resistance, the result being the slow formation of a sinus or several sinuses, ultimately connecting with the surface.

This description, from my point of view, is a very good definition of the pyorrheal stage of interstitial gingivitis.

The sinus in the pyorrheal stage of this disease is between the root and the alveolar process, unless the lesion be so deep in some place on the outside of the process that a gingival abscess is formed. In either event the alveolar process is continually bathed in pus, which results in its destruction.

So long as the tartar is present as a foreign body the irritation is continuous and sequestra are formed which are a second source of irritation until they are removed or absorbed.

All these cases will heal by removal of the deposits and sequestra or by the loss of the tooth. The removal of the teeth invariably results in recovery and a patient without teeth, either young or old, can not have the disease, regardless of transitory structures, degeneracy, heredity, drugs, environment, or systemic disease. If lesions of the gums or maxillary bones appear where there are no teeth, it is not interstitial gingivitis, but something else.

### DISCUSSION.

**Dr. Eugene S. Talbot**, Chicago—While it is possible that gutta-percha will be tolerated at the apical foramina more readily than a steel broach, yet to understand the pathology arising from such irritant we must first take into consideration the structures involved. We can not compare the peridental membrane and the alveolar process with other structures of the body. The alveolar process is a transitory structure. The tooth to a certain extent is a foreign body. The alveolar process and the peridental membrane, unlike the other structures, have not come to stay. It is waiting for the least irritation to set up absorption and destruction of the peridental membrane. While it may tolerate gutta-percha better than metal, in either case the irritation produces absorption and destruction. It will not encapsulate foreign substances like other tissues. I have demonstrated this many times in many ways. Neither can we contrast a pulp like that of a human tooth with that of an elephant's tusk or a pulp that is persistent. The pulp is practically a degeneration, even in health. The expansion and contraction is *nil*, hence pulp stones and frequent inflammation result in abscess of the pulp without pain. The restricted portion of the apical end of the root restricts repair. The constitutional causes of interstitial gingivitis have local action because the gums are a secretory structure and because of the transitory nature of the gums and alveolar process; next to the nervous system, they are always the first involved. The arteries, nerves and veins terminate in this structure. They come up against a blank wall or nearly foreign substance, the root of the tooth, hence it may be called a terminal structure. I agree with the essayist that tartar invariably produces interstitial gingivitis, and in that case is entirely local in its origin, but the constitutional variety may best be illustrated in something like eighteen or twenty syphilitics that I have had in my practice for a number of years. By local treatment I am able to practically restore the gums and alveolar process to health, and the patient leaves my office after a given length of treatment feeling well, but invariably he returns, sometimes in six months, a year or two years, with marked interstitial gingivitis. What is true of syphilitics is also true in consumptives, diabetics and auto-intoxications of all varieties. The calcareous deposits are no doubt irritating to the surrounding tissues. They should in all cases be removed.

**Dr. A. E. Baldwin**, Chicago—I think we, as a profession, ought to define our premises a little more closely than we do and then we could have much more intelligent and accurate discussion. As, for instance, we speak of degeneracy being a change from the normal. The first essential is to fix on the data for the normal. Without this we would be discussing largely in the dark, because every one's standpoint might be different as to the point taken for normal. The statement has been made that the pulp itself is a degenerate condition. Before I could accept any such statement I should want to know very definitely what is considered normal. The essayist speaks of the tolerance of the tissues for certain things, and mentions an illustration of seventeen years' standing. I think the position taken by the essayist that there is an apparent tolerance is well taken. I had a similar case in my own experience in a left lateral superior incisor. There was no irritation. I removed the substance later and intended to make an examination of it, but in the moving of my office it was lost.

**Dr. G. L. Curtis**, New York City—The tolerance of the tissues for foreign substances varies according to the nature of the substance. I have in mind the case of a child who stepped on a headless pin, which a physician, when he reached the house, could not find. Three months later the pin came out at the hip. I know a man who has carried one-half of a large aspirating needle in his leg for twenty years. It had evidently lodged against the bone and did not take the usual course of passing through the soft tissues. I suggested the use of the *x*-ray, but he said he would be more comfortable if the needle were not found, as he was in good health. I can not agree with Dr. Talbot as to the tooth being foreign substance, unless he considers the tooth a degenerated foreign substance. I believe that when the tooth is developed it begins to degenerate. I think gutta-percha is better tolerated than any other substance. I believe some instructive lessons might be gained from the use of the *x*-ray. The syphilitic phase of interstitial gingivitis is one that has interested me for many years. I have felt that many, if not all, the recurrent cases of gingivitis are due to syphilis. When the inflammatory process returns, following thorough local treatment, I have found that the cases usually do well under syphilitic treatment, and in a great many such cases I have proved beyond doubt the presence of syphilis. It is not always acquired by the patient, but is sometimes inherited. We know that the child of a syphilitic parent has syphilis. These cases are perhaps the most difficult to treat because of the lack of definite history. I have gained my knowledge more particularly through the study of blood. The germ or spore of syphilis is detected in the blood. Dr. Rhein told me recently of the author of that discovery, and I have known for some ten years that it was possible to find the spore of syphilis in the blood of syphilitic patients. I believe that wherever I find the syphilitic spore the patient bears the mercurial treatment well, and if placed on very mild preparations of small doses of the red oxid of mercury he improves. I usually give a sixteenth of a grain three times a day, increasing it to one-fourth and continuing until the spore disappears. If the treatment is persisted in for months one can eliminate the degenerative condition which maintains syphilitic gingivitis.

Dr. M. L. Rhein, New York City—We have at times been accustomed to the use of terms that were rather exaggerated, and I was very much pleased to hear Dr. Fletcher make use of the term "sapremia," instead of septicemia. I am convinced that we see very few cases of real septicemia, and that the one case he cited is a distinct exception to the general run of cases which are sapremic. From a surgical standpoint I take exception to the view of the essayist regarding the after-effects of extraction of a tooth under the circumstances cited. I can not conceive of a case of this nature in which surgical interference can be objectionable or be a potent cause for evil.

The essayist's view that the extraction of this tooth may have had considerable bearing on the fatal ending of the case seems to me contrary to all accepted surgical principles. Furthermore, it brings up the question frequently met, whether because of the presence of pus it is not advisable to delay the extraction of a tooth. This is a question well worth consideration. My clinical experience with the use of gutta-percha leads me to believe that it is tolerated in the most remarkable manner by the soft tissues. I could cite a number of interesting cases bearing out this view. If there is a substance which the tissues will tolerate more freely than gutta-percha it is perfectly fused porcelain. This has been demonstrated by the wonderful tolerance shown by the tissues around a porcelain root after the amputation of a necrosed root in one of the multirooted teeth and the attaching of a porcelain root to the crown. I am totally opposed to the extreme views that Dr. Curtis takes, that almost all cases of recurrent pyorrhea or interstitial gingivitis will show a distinct syphilitic origin and that the syphilitic germ can always be demonstrated in the blood. Dr. S. Lustgarten has the credit of making this discovery twenty-five years ago, but it is well-known that the matter is disputed at the present day.

Dr. Hans Pilcher, Vienna—Beside gutta-percha, paraffin is well tolerated, as the surgical use of this substance shows. Dr. Trauner of Vienna has used it with success for the filling of old cavities with open foramina before the development of the teeth is completed.

Dr. Curtis—I think the question of extracting the teeth in the presence of inflammatory processes would depend entirely on the individual case. In this case I have no doubt the extraction did much to hasten the fatal ending. I think there was an acute inflammation established by infection of the fresh wound caused by the extraction of the tooth. I therefore believe it better to temporize with these cases and try to tolerate this inflammatory process until the greater part of the trouble has been disposed of. Ordinarily speaking, I think the extraction of these teeth is wise, but never when the extraction is liable to extend the inflammation.

Dr. George F. Eames, Boston—When Dr. Talbot said that when we consider the tolerance of foreign bodies in these tissues we must take into consideration the structures involved, he might well have said also, that we must take also into consideration the general condition of the patient himself. It seems to me that this explains the very great difference in patients tolerating, not only foreign bodies, but all toxic irritating substances. As to the extraction of teeth in the condition named by the essayist, while it would seem that the surgical principle of removing the irritant at once could obtain in most dental cases, yet we have on record a number of cases in which very serious results have followed the extraction of teeth, when infection had extended from one tooth to another, causing their loss and resulting finally in death. I believe this must be due to fresh infection of a surface reopened and that there is some truth in the statement that we should get rid of the infection by some other means.

Dr. M. L. Rhein—I certainly feel from considerable observation that all such cases are due, not to the extraction, but to the faulty surgical treatment.

Dr. W. E. Walker, New Orleans—I think that death is not due to extraction, but to the faulty technic. Who can say in many cases that death would not have resulted had extraction not been done? In many of these cases of suppurative osteomyelitis, simply removing the tooth is not sufficient. The marrow of the bone is permeated with pus and should be treated. The whole mouth should be treated with antiseptics and the socket should be injected with antiseptics. Considering the tooth as a foreign substance, as Dr. Talbot has said, and being the cause of gingivitis, I think is putting the cart before the horse. I believe if we were to use the word inflammation more carefully and not consider as inflammatory conditions those which are simply passive hyperemia, we would be more correctly understood. In early stages of so-called interstitial gingivitis or Rigg's disease I believe the tooth is not an irritant primarily, but that the disease is due to some local or constitutional condition together with lack of exercise. In the majority of cases we have an accumulation of venous blood and because there is not the normal stimulus due to mastication the faulty general circulation becomes more manifest in the gum tissue. This passive hyperemia keeps the tissues overfilled with blood which does not contain sufficient oxygen for the tissues. We know that the cementum contains numerous layers which have been put on during the life of the individual. This, I think, seems to demonstrate the fact that the fibers of the cementum have but a limited life, and that additions of fresh cementum are necessary to entangle fresh fibers to hold the tooth. The connective tissue is exposed and we have an oozing of serum which is rich in lime salts. Precipitation of these salts occurs and there is then the additional mechanical irritation of the calculus so formed, which is not the cause of the separation of the tooth, but the result.

Dr. E. S. Talbot—Dr. Walker misunderstood me. I did not intend to say that the tooth as a foreign body produced irritation. It acts somewhat as a blank wall.

Dr. M. H. Fletcher—Dr. Talbot's position as to the transitory condition of the alveolar process should apply equally well to the hair and nails and to tubercles of bone produced by the pulling of muscles at their attachment. The form of any bone in the body may be changed by continuous pressure as well as the alveolar process and yet the former is not considered transitory. If the human nail is not transitory why is it not like the baboon's, twice as thick? The alveolar process and teeth are called transitory structures, but I fail yet to see why they are not susceptible to repair as long as they are alive. It seems to be a fact that the organisms of the universe are losing certain structures for the benefit of the organism itself, but I have failed to be convinced that the transitory structures, as such, need necessarily be subject to disease more than other structures. The matter of production of *interstitial gingivitis* by medicines, syphilis or by other systemic causes seems to me so difficult to prove that I take the opposite view until it is proved. While I admit that those who have spoken have reasonable grounds for their opinions, I feel that I have reasonable grounds for the opposite. My paper did not give sufficient details about the death from extraction. The gums and the alveolar process were in the worst possible state, there being a gangrenous and sloughing condition about all the teeth. It is possible, as Dr. Walker suggests, that the patient would have died without the extraction; but knowing the case as I did, I believe had the treatment been temporized, as suggested by Dr. Curtis, the life might have been spared. The railroad surgeon having this case in charge was originally treating it for acute tonsillitis.

Dr. Rhein—Do you suppose, with the condition of the worst possible kind, that after removal of the tooth, if the proper germicidal agents were kept in that socket for a sufficient length of time, there would be any possibility of infection in that particular case?

Dr. Fletcher—I believe it is practically impossible to sterilize an open bone wound unless all dead bone is removed. The deeper one scrapes, the larger the blood vessels which are opened. I think the extraction of the tooth, with the addition of this zone of uncovered bone to the already septic condition, turned the case downward instead of toward recovery.

# ARTHRITIS DEFORMANS.

## THE REPORT OF A SERIES OF ONE HUNDRED AND TEN CASES FROM THE JOHNS HOPKINS HOSPITAL.

(FROM THE CLINIC OF PROFESSOR OSLER.)

THOMAS McCRAE, M.D., M.R.C.P. (Lond.)
THE JOHNS HOPKINS HOSPITAL.
BALTIMORE.

(*Continued from page 8.*)

### DIAGNOSIS.

Undoubtedly an essential thing in a correct diagnosis is a knowledge of the fact that arthritis deformans often occurs as an acute polyarthritis, with a sudden onset, and that unless care is taken the condition is especially apt to be regarded as acute articular rheumatism. Here, as is usually the case, knowledge of the possibilities is an essential to correct diagnosis. It may be taken for granted that the advanced stages with the marked characteristic deformity are not likely to be mistaken, but of what value is diagnosis then when the possibility of preventing these later changes is the hoped-for thing? Practically, the study of the diagnosis will be confined to the early stages. The more acute forms have to be diagnosed, especially from acute articular rheumatism, acute gout, acute polyarthritis from other causes (for example, septic conditions, etc.), and gonorrheal arthritis.

*Acute Articular Rheumatism.*—There are several features that give one help in the diagnosis: the first, it may be said, is the knowledge of the two diseases. The polyarthritis of arthritis deformans rarely shifts from joint to joint. When the joint is once attacked, it rarely clears up suddenly. One seldom sees the rapid disappearance of arthritis in a given joint, which is so characteristic of rheumatism. The joints rarely show the severe local tenderness of rheumatism. There may be redness, but it is rarely extreme. The swelling is often marked, but in many of the joints it is distinctly more in the surrounding structures than in the joint itself. There may be effusion, especially in the knee joints. Certain joints are often involved which are rarely concerned in rheumatism, especially the joints of the neck and the temporomaxillary joint. The involvement of the fingers is often especially characteristic. We may find that only two fingers are involved, very commonly the middle or ring fingers, or it may be the first finger and the thumb. There is a curious appearance often given by the fingers, really the early stage of the "fusiform" condition. This we have found of considerable help. The temperature is usually not very high, and it may seem low in proportion to the amount of arthritis. The pulse is nearly always above normal. If this persists after the subsidence of the acute features, it is a very suspicious factor. The enlargement of the lymph glands, especially those associated with the affected joints, speaks for arthritis deformans. The absence of cardiac involvement and the usual lack of any help from the use of salicylates, is often an important point. Another suggestive fact is the common rapid muscular atrophy. Undoubtedly in prolonged cases of rheumatism one sees considerable atrophy, but it rarely appears with the rapidity that it does in arthritis deformans. The early atrophy of the interossei muscles is especially to be noted. The exaggeration of the reflexes is a point to be kept in mind. Then, too, the case is apt to drag on, the temperature perhaps remaining at 99 F., or slightly over it, the pulse rate increased, and the joint symptoms persisting. This is always suspicious, and in case of a diagnosis of acute rheumatism, should always lead to a careful re-examination of the case. If after the acute symptoms are over joint deformity or alteration persists, one should always reconsider a diagnosis of acute rheumatism.

*Acute Gout.*—This is not likely to be a frequent cause of difficulty, but it is a possibility. The common alcoholic history in such patients, the attacks usually clearing up rapidly and leaving little damage in the joints, and the results of uric acid estimations, should all prevent error.

*Gonorrheal Arthritis.*—This is likely to give difficulty in diagnosis only where several joints are involved. If one cultivates the habit of always keeping gonorrheal arthritis in mind, and searches carefully for gonococci, there is not likely to be much possibility of mistake. In all doubtful cases of polyarthritis one should cultivate a "suspicious" frame of mind toward the diagnosis of acute articular rheumatism, and make it not first but last, and after other conditions have been excluded.

From various unusual joint conditions there would seem to be little difficulty in distinguishing arthritis deformans, and this group does not require discussion.

One is much impressed in going over the histories of our cases with the very common diagnosis of acute rheumatism made in the previous attacks. Often there are little facts mentioned which are enough to clear the diagnosis. Thus, several patients have said that their doctor commented on the fact that they had acute articular rheumatism with very little fever, or that they had a great deal of thickening left about the wrists or hands after their rheumatism. It is a good safe rule always to hold grave doubts as to the correctness of the diagnosis of acute rheumatism when there are permanent changes left in the joints after the acute attack is over.

Regarding what may be termed early minor manifestations of the disease, I do not know that any one has written better than Dr. Spender, in the article in "Allbutt's System of Medicine." There may be merely vague pains about the ankles or wrists, or the patient may complain of pain in one joint perhaps associated with some injury or a sprain. There may be some weakness of the wrists or hands. There may be curious neuralgic pains about the joints. As Spender says, these should always attract careful attention, and a thorough examination should be made. Of some of the other special points in the diagnosis to which Spender drew attention, note may be made. He emphasizes especially the rapidity of pulse. This, as we have already said, seems an important point. The various areas of brown pigmentation, especially on the face, neck and forearms of which he speaks, have not been of any especial assistance, and there would seem considerable doubt of their distinct association with the disease. The coldness and sweating of the hands do occur frequently, but it is probably more often associated with neurotic conditions, by no means a rare accompaniment of arthritis deformans. As Spender says, the diagnosis of rheumatism, muscular rheumatism, sprains, etc., are all pitfalls into which we are too apt to stumble.

### TREATMENT.

In the discussion of this matter we are again met with the fact that there are two great groups of cases, the early and the late. The treatment in the first may undoubtedly be of great help as a preventive measure of farther damage. In the latter condition it can be only palliative, although even here much good may be done. We may first discuss the treatment of an acute attack. Patients are better at rest, and probably it is well to keep them clothed in flannel. If there be much fever the diet should be liquid. Ordinary attention should be given to the bowels. For remedies for the pain we have found that salicylates are of comparatively little use. Antipyrin in doses of 5 grains is often effectual. Guaiacol is highly recommended by some. Small doses of codeia may be used; morphia seems to be rarely required. Of local measures to the joints the ice bag sometimes gives considerable relief, or the wrapping of the joint in cold compresses surrounded by oiled silk. These may be kept on constantly. Oil of wintergreen or lead and opium lotion applied locally is of some help. The hot air baking very often gives relief to the pain. Gentle massage may be of use. In spite of all measures, in some cases the patient is but little relieved. After an acute attack, whether the patient be absolutely free of symptoms or has some damage left in the joints, the great principle of treatment seems to be keeping up the nutrition. The patients should be out of doors as much as possible. They should be given all the nourishment they will take, and this of a general kind. The mistake is too often made in considering these patients to be rheumatic or gouty, and meat is almost totally cut off. On the contrary, a full meat diet seems especially helpful. They should be given nourishment between meals and at bedtime, and every effort made to improve their general condition. With this, of course, local derangements are to be carefully treated. Carious teeth and pyorrhea alveolaris should receive attention. Any stomach or bowel disorder should be remedied, and every endeavor made to keep the patient under the most favorable conditions. General massage is usually helpful. Concerning the various forms of bathing no general rule can be laid down. In England there can be little doubt of the benefit of such waters as at Bath. In this country, while some patients are doubtless helped by the bathing, many others are made distinctly worse. That this is due to too prolonged hot bathing to the point of depression may be possible, but our cases rather suggest that great caution should be exercised in advising, at any rate, any severe course of baths.

The local treatment of the joints is very important. First comes massage, which in the beginning ought to be given by an assistant. But as a general rule later on the patient should be encouraged, as far as possible, to rub himself. There is usually the double benefit to the joint rubbed and to the hand employed. The hot air treatment is especially useful in many of these cases. The oven may usually be heated to 350 F., with perfect comfort to the patient, the importance of short applications being always kept in mind. Probably the majority of cases are helped most by periods of only twenty to thirty minutes in the hot air bath, and periods of an hour and an hour and a half are undoubtedly, in many cases, positively harmful.

The question often arises as to the amount of use that should be made of the affected joints. Leaving out the acute attacks, as a general rule, the more the joints are used the better. The mistake is often very serious when the patient is put to bed and any attempt at using the joints discouraged. The benefit of use is well shown by the temporomaxillary joint, which, although frequently involved, relatively rarely shows permanent damage. These measures may result in great improvement, even in a far advanced case, as, for example, in Case No. 70, that of a woman who for eighteen months had been bedridden, had been unable to feed herself, and who had some teeth pulled in order to be fed. After three months of treatment she was able to walk moderately well, could dress and feed herself, and open the mouth fairly well. Such cases are, of course, not common, but they serve to show that the outlook is not always without hope. There are two things necessary, probably both in the physician and in the patient. These are perseverance and patience. There are probably few cases, even of advanced disease, that can not be at any rate helped by persistent, patient, systematic treatment.

By far, however, the more important group, as regards treatment, are the early cases. As has been stated, too often these are regarded as rheumatism for long periods, until the damage is done. In these, when recognized early, the most important element in the treatment seems to be good nutrition. General good hygiene, lots of fresh air and sunlight, and an abundance of good food are essential. Great care should always be taken to be on the outlook for the slightest manifestations of a return of the symptoms. Every slight infection should be regarded seriously. We are unable to say how successful early recognition of the disease and persistent care may be in preventing late attacks and permanent damage. At any rate, the patients should have the chance.

In addition to all the measures previously spoken of, there seem to be two drugs which are especially useful. These are the syrup of the iodid of iron and arsenic. They may be given alternately or combined, but in any case their administration should be kept up over long periods of time, for months, or if necessary, even years, at intervals.

*Surgical Treatment.*—This in some cases holds out a hope of benefit. In certain of the cases with marked contractures, the tendons may be divided and the limbs straightened. In other instances, under an anesthetic, a bent limb can be forcibly straightened and put up in plaster for a few days, but it can not be kept too strongly in mind that the best treatment for these cases of contractures is the preventive one. It is not, however, always in our power to carry this out, as the patients frequently delay consultation until permanent contractures have been established. Of excision of the joints we have had little experience, but it is undoubtedly of use in certain cases. It is probably most likely to be useful in the knee or elbow joint. It may serve to give a more useful limb. In some instances, too, the excision of the joint seems to be justified on account of pain. We see patients suffering with constant severe pain which nothing relieves; excision of the joint frequently gives great relief and the patients are left with about as good a limb as before. In some cases operations on the hip have been of considerable use. It must be said, however, that as yet we have hardly enough statistics on which to draw any definite conclusions on the value of surgical intervention.

It can not be too strongly emphasized that in this and so many other diseases the great requisite to intelligent treatment is proper diagnosis; and this, in the majority of cases, would seem not such a difficult matter if the profession once realized the frequent occurrence of this disease and the fact that it is so often taken for acute rheumatism. It may also be said that prevention is often more possible and certainly more hopeful than cure.

### PROGNOSIS.

This is usually rather gloomy. The general tendency of the disease is to progress, but we have to remember that in many cases the disease was never diagnosed until more or less permanent changes had occurred. How much can be done for early cases with early diagnosis we hardly have data to state. Reports have been obtained from 25 of the patients who had been in the hospital over three years ago. Of these only 2 could be described as well, 3 had died from an unknown cause, but only about half the remainder were much worse, 4 were crippled completely and 5 were only able to get about with crutches. The other half were much in the same condition.

There can be no doubt of the necessity of always giving a most guarded prognosis. They may recover, which is unlikely so far as our present knowledge goes, but we can generally only hope to keep the disease stationary by care and perseverance. It is to be hoped that early diagnosis may help the patients of the future.

### "STILL'S DISEASE."

To this only brief mention will be given. There is some doubt as to the exact nature of these cases, but at present it seems best to include them among the cases of polyarticular arthritis deformans.

There were two cases in our present series, one a male aged 4, and one a female aged 5 years. They both had rickets, but there was no history of symptoms suggesting congenital syphilis. They both showed the symptom complex described by Still, namely, (1) an arthritis involving many joints, and with more change in the periarticular structures than in the joint itself; (2) an enlarged spleen, and (3) extreme enlargement of the lymph glands.

One patient was discharged somewhat improved, but the other went out completely well—one of the very few instances of recovery from this condition.

These cases seem to suggest an infective cause very decidedly. In the case with recovery the enlarged spleen and glands diminished with improvement in the general and articular condition. It seems most reasonable at present to consider them a type of arthritis deformans.

### GROUP III. MONARTICULAR FORM.

These comprise a group of cases about which there is also much difference of opinion. The frequency is doubtful. Probably many of the cases often diagnosed as chronic rheumatism belong here, and also the group termed *Morbus coxæ senilis*. The disease usually occurs in elderly people, one of the larger joints, most often the shoulder or hip, is involved and the general type of change is degenerative. There is usually marked loss of function, wasting of the muscles about the joint, and sometimes ankylosis in the hip joint. In these patients very careful examination should always be made for slight changes in other joints. These may be very slight, but in some of them undoubtedly other affected joints may be found.

There are only 3 cases of the monarticular type in this series. The more chronic cases do not often seek hospital advice. The condition may not seriously interfere with their comfort, and they are content to make the best of it. Curiously enough, two of these cases suggest in some ways an acute onset much like that described for the polyarticular form.

The symptoms may be noted briefly. Two of the patients were females, all were white, the ages were 39, 40 and 50 years. In two the shoulder was involved, and in one the hip. The former complained of pain in the hip and leg. In both the shoulder cases the onset had been rather sudden; they complained principally of pain and difficulty in moving the joint. Later the pain became less, but limitation of motion was left. The third case was more gradual. There was pain in the hip and down the leg, with gradually increasing stiffness.

The symptoms were much the same in all—pain on motion, distinct limitation of motion, crepitus, and some muscular wasting. In one of the shoulder cases the reflexes on the affected side were much exaggerated and normal on the other side. She also showed signs of slight involvement of two finger joints on the other hand. There were also some areas of pigmentation. The temperature in two averaged 99 F., in the third it went up to 100.5 F. The pulse rate in all was about 90.

The diagnosis in these cases may offer some difficulty. A gonorrheal arthritis can usually be excluded, and the greatest trouble generally is to distinguish it from a tuberculous joint. If the characters of the joint involvement do not give the diagnosis tuberculin may be used. We have found it very satisfactory. The finding of slight suggestive changes in other joints is conclusive.

Treatment is usually only palliative. Local measures, massage, wet packs, etc., are often of use, and in some instances surgical measures may give a more efficient joint, especially at the hip. But too often the degenerative changes advance gradually as in the polyarticular form. Every endeavor should be made to keep up the general health.

*(To be continued.)*

---

**Pulmonary Emphysema from the Life-Insurance Standpoint.**—Among the addresses delivered at the Third International Examiners' Congress held at Paris recently, was one by E. Hirtz of Paris on the above theme. He insisted that every subject with pulmonary emphysema with symptoms at the apices and distinct resistance to percussion and whose general condition is only fair, should be regarded as a bad case for insurance. Also every subject with emphysema who registers less than 2,000 c.c. in spirometric tests. The candidate should be absolutely rejected if the difference between the breast measure during forced inspiration and expiration is less than 3 cm. with heart and arteries not in a normal condition. The difference between the breast measure during forced in and out-breathing averages in health 7 cm. This difference drops to 5, 4 and even 2 in case of emphysema. The findings of this test always parallel those obtained with the spirometer. He attributes much greater importance to the latter than to the pneumometer, citing Lermoyez to the effect that "we diagnose emphysema with the ear, but we prognose it with the spirometer."

# URETHROTOMY BY THE COMBINED USE OF AN ANTERIOR AND POSTERIOR SOUND USED AS GUIDES,

## THE LATTER BY MEANS OF PREVESICAL PUNCTURE WITH A CURVED TROCAR CANNULA DESIGNED FOR THE PURPOSE.

G. W. PENN, M.D.
HUMBOLDT, TENN.

The genito-urinary surgeon or the general practitioner of medicine is confronted with no graver condition in the routine of practice than the fortunately rare impervious urethral stricture, as, with the patient anesthetized and the structures covering the urethral site divided, with or without a Wheelhouse staff or other guide, down to the stricture, he finds it simply impossible to locate the proximal lumen, or anything resembling the mucous membrane of the urethra.

It is a well-known fact that the best genito-urinary surgeons are frequently baffled by this condition, and utterly fail to enter the bladder by the ordinary methods of urethrotomy, with or without a guide. The statement, "with a guide," refers to a catheter or staff introduced via the meatus and extending only down to the stricture, the usual meaning, "with a guide," obviously not being intended, since, of course, no difficulty could ensue if even the smallest filiform could be passed into the bladder.

The Wheelhouse operation has stood the profession in good stead for many years, and especially is this true of the vast majority of surgeons not skilful enough to perform the difficult operation of Cock, and it is in just these cases, especially those in which the latter operation can not be done, and resort is compelled to be had to suprapubic cystotomy, that I propose a procedure to be described presently. Indeed, it seems to me that Cock's operation is never justifiable when it is demonstrated that other methods consuming half the time and offering incalculably less difficulty in performance are at hand; this is also true of cystotomy for the purpose of posterior catheterism, when done simply as a guide.

That we can not explore the perineum of a patient and do extensive dissection of the parts in a vain effort to enter the bladder from below without an unwarranted amount of shock, goes without saying, and has more than once, even in skilful hands, resulted in death from urinary infiltration and sepsis.

The operation of suprapubic cystotomy is very generally used by most surgeons at the present time for the purpose of posterior catheterism in cases impossible of performance by any other means, and it seems to me that it has been to the discredit of surgery that it has been only employed as the operation of necessity, rather than the operation of choice, since the advent of the present era of asepsis has rendered it a safe procedure. I will undertake to show that this operation is indorsed by many men of large experience in the impossible perineal cases by anterior methods, and then having clearly shown the advantage of the posterior or intravesical method, I hope to indicate a method better than cystotomy, in regard to ease of performance, saving of time, avoidance of so extensive trauma, and hence a minimum or absence of shock and a practical elimination of after-treatment as regards the suprapubic wound.

In a paper on suprapubic cystotomy for retrograde catheterism as a guide in these cases, in the *International Journal of Surgery* for October, Howard Crutcher quotes from the personal experience of several men whose statements will be accepted as authoritative, the tenor of whose utterances brings forth no uncertain sound. Since the establishment of the suprapubic route is a matter of such consequence to this unfortunate class of cases, as well as to the good showing of the case records of the surgeon, I take the liberty to repeat some of the quotations as used by Dr. Crutcher in his able and instructive paper, some of which are evidently from personal letters to him. Bernays says:

> I simply got lost, and my only way out of trouble was a suprapubic section, which permitted retrograde catheterism. I make this confession and authorize you to use it in your paper. I will say, in addition, that I have never been in that fix since then, and am a great friend of the Cock operation. I have done Cock's operation over fifty times, always with success, in cases of impermeable stricture. In 70 per cent. of these cases a urethra can afterward be established by the ordinary methods of dilatation. In some of the others a perineal opening may be permanent.

As Dr. Crutcher pertinently says, the success of Bernays' cases can not be taken as the criterion of other less skilful operators. In the same paper he quotes Halsted as saying:

> I can not give you the details, but I know that it seemed to me, at the time, impossible to reach the deep urethra in any other manner. I think that almost every surgeon of large experience in genito-urinary work has found it necessary, occasionally, to resort to this procedure.

Speaking of his two cases, Murphy says:

> Both of these cases were in the acute stage (gangrenous) from the urinary infiltration. One was the result of a physician having attempted to pass a sound; the other resulted from traumatism in the perineum. Both cases had been neglected, and in one the infiltration was so great that the subsequent gangrene destroyed the corpus spongiosum in its entire length, and the urethra from the prostate to the meatus, as well as the dartos and scrotal tissue, so that the testicles were exposed and had to be covered with flaps from the thigh. The final urethral opening was deep in the perineum. In both of the cases the urethral catheter was passed from above downward and perineal drainage instituted. When I was an interne in the County Hospital I saw two cases of this kind operated on by attending surgeons, both of whom performed what is known as Cock's operation, and both patients died.

Valentine says:

> It seems to me a general proposition that suprapubic cystotomy is required in obliterative changes (as from traumatism, urinary infiltration, suppuration) which prevent the finding of the urethra via the perineum. Indeed, I do not appreciate what other recourse one can have in such a condition, when the bladder can not be reached through the urethra.

Lydston says:

> I consider a retrograde exploration and instrumentation via a suprapubic cystotomy much safer than a prolonged and tedious search for the urethra via the perineum. I have been practicing it for ten years. I rarely fail to enter the bladder perineally, but when I do not succeed within a moderate time, I go in above.

Matas says, in part:

> In a large experience in external urethrotomy for stricture, covering over eighty-five cases in fifteen years, I have been compelled to perform retrograde catheterism by suprapubic cystotomy in four cases in all, every time successfully and with the most satisfactory results. In all but one case there were perineal fistulæ, and in all I had to resort to suprapubic cystotomy after failing to find the lost and displaced vesical end of the canal. Notwithstanding prolonged and careful dissection of the perineum, I was led to adopt this procedure after losing a patient in my earlier practice, by attempting to tap the bladder in the perineum by Cock's method. . . .

> My success with retrograde catheterism by the suprapubic route has led me to adopt and recommend this as a regular procedure, to be utilized at a much earlier moment in the operative act than I would have adopted in former years. This method is far preferable to a long, exhausting and traumatizing search made in the perineum in difficult cases, more especially in those chronic, neglected cases of stricture in which the perineal and periurethral tissues are riddled with fistulæ and sinuses opening in a mass of hardened cicatricial tissue resulting from periurethral cicatricial abscesses and infiltration. In such cases the urethra is often obliterated for a considerable distance, and the channel is tortuous, deviated and displaced, so that its normal anatomic bearings are lost or unrecognizable. In such cases a filiform can not be introduced and there is no possible guide to the urethra. . . . I claim that it is a most safe and reliable expedient, which should be resorted to much earlier and oftener than is now done in difficult cases.

Such commendation of the suprapubic route from so good an operator as Matas should carry great weight, and surgeons should not permit "Operators' pride" to impel them to a tedious and prolonged dissection of the perineum, impairing the facility of its tissues to assume the functions of the urethra, in those cases in which a new channel is made, and greatly increasing the perineal trauma, with its consequent tax of nerve power and lowered resistance, and hence greater liability to sepsis.

Crutcher's own experience with the suprapubic route is four cases, all of which recovered, and which he says, "appears remarkable when it is borne in mind what an amount of senseless perineal traumatism was inflicted on some of them."

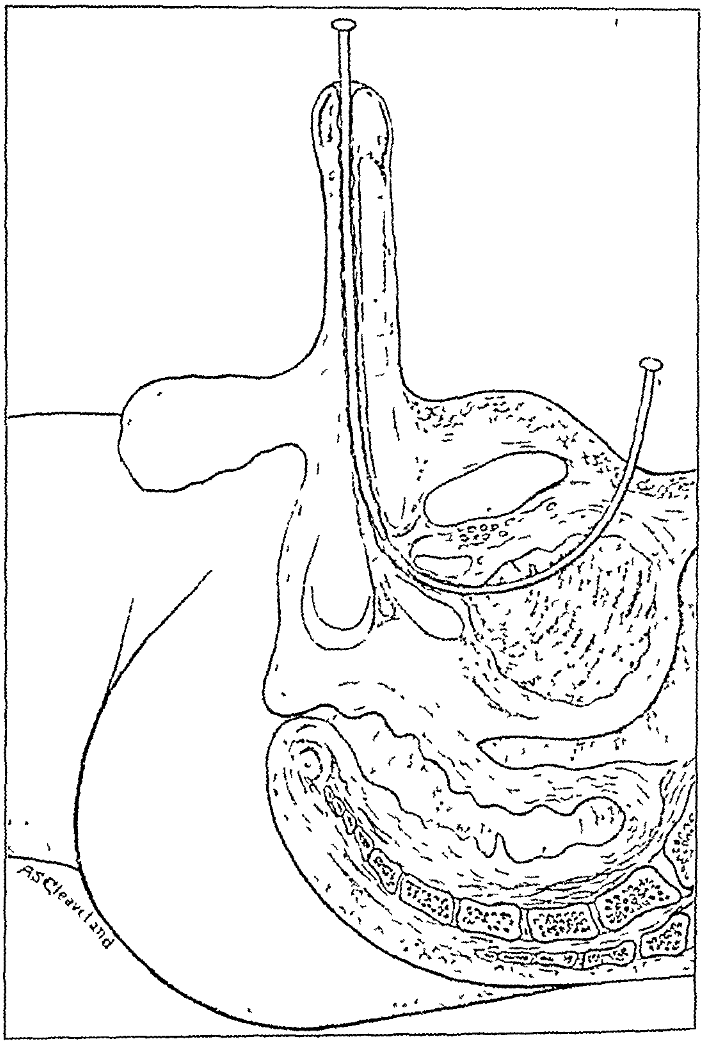
In the American Text-book of Genito-urinary Diseases, Lydston says:

> Should it be impossible to pass a guide through the stricture after its anterior surface has been exposed, the urethra may be opened up posterior to it, and an attempt made to pass a probe or bougie from behind forward. Failing in this a dissection must be made from before backward in the normal direction of the urethra. In a case of this kind the author would be inclined to perform suprapubic section and retrograde catheterism. This procedure has on several occasions been invaluable to him

While it is true that some operators of large experience have never met cases in which there were complications compelling a resort to the upper route, the testimony of those quoted is sufficient to establish beyond cavil the comparative frequent occurrence of such cases I believe the use of a posterior guide is neglected far too often; even though it could only be done by suprapubic section; but when it is shown to be perfectly feasible to thus certainly locate the urethra by suprapubic puncture, with no more trouble and no more danger than a simple palliative aspiration of the bladder, neglect of a means so available converting one of the most tedious and difficult operations in surgery into one so simple and easy of performance that a tyro can do it, is certainly a reprehensible omission.

My experience with suprapubic puncture for this purpose is confined to two cases, but the results of both were so perfect, and the cases, which were both due to extensive trauma, and to which I had gone realizing the prospects of trouble, born of a knowledge of the usual difficulties, were converted into so simple a problem that I wondered at my previous trepidation. The adoption of prevesical puncture for posterior catheterism as a guide was largely the result of accident—at least, its employment was not the outcome of systematic study of the question, it never having occurred to me to think of any other alternative should I meet a case of impermeable stricture not operable by other means than suprapubic section. I will describe the case in which, on Sept. 20, 1899, I first used the measure under discussion.

The patient was a negro man about 55 years old. He had received an extensive injury to the perineum by falling astride a wagon wheel while attempting to jump from the vehicle. A ragged laceration of the urethra resulted, accompanied by general inflammation of the periurethral tissues and perineum. Retention of urine was complete for twenty-four or forty-eight hours. I did not see the case until four months after the accident, and in the meantime an external urethrotomy was done by the Wheelhouse method; the operation, however, afforded only temporary relief, not being followed, as it should have been, by the usual dilatation with sounds. At the time I saw the case retention was complete, and tapping had been resorted to the two previous days.



Prevesical puncture as a guide, seen in sagittal section

The perineum presented a very swollen, fistulous surface, with pus discharging from several places. I felt sure that the scars from the original wound, supplemented by those of the former operation and the present infected and misshapen condition, would make an entrance into the bladder from below impossible, and, while considering the case, the patient demanded relief from the distended bladder, which was paining him very much. Realizing that I would have to repeat the vesical aspiration, it occurred to me that I could use the cannula as a passage or pilot for a post-urethral guide, without resorting to section, and the unsanitary surroundings led me to believe that this would be less liable to cause infection and would also expedite the performance of the operation very materially. With this idea in view, I bent an ordinary cannula of medium size, similar to those accompanying a Pravaz aspirating syringe, with the trocar *in situ*, thus preserving a pervious and uniform caliber throughout. The curvature was slightly less than that of a urethral sound, since I believed that any discrepancy between the urethral curvature and that of the cannula could be overcome by the facility with which the position of the cannula itself could be shifted, owing to the great degree of invagination above the pubis the mobility of the abdominal wall would permit, and which also constituted the fulcrum at the point of puncture. I inserted the trocar and cannula thus prepared, aspirated the urine, washed out and refilled the bladder with salt solution as an aseptic precaution and also to prevent collapse of the vesical walls, impeding catheterization, and, grasping the penis, that the urethra might present as few obstructing folds as possible, a long silver sound, bent in its entirety to the same arc as the cannula, was introduced, and it immediately dropped into the dilated proximal urethra; the usual dilatation of the urethra, posterior to the stricture in these cases, augmented greatly the ease of the procedure. Another sound was held in position in the penile urethra, as is usual in external urethrotomy. The penis was held in an extended position by an assistant, and the ends of the two sounds could be distinctly felt in the perineum, separated from each other about an inch and a quarter. An incision was made between the two, a catheter introduced, all pockets laid open, cleaned and drained, and the wound simply dressed with gauze, owing to the bad and suppurating condition of the parts. The little puncture in the anterior bladder wall demanded no dressing, it amounting, of course, to no more than an ordinary puncture for the relief of distended bladder. Considering the bad condition, the patient made a rapid recovery and got well with a fairly good urethra. Ether was the anesthetic used in this case.

My second case was very much like the first, except that there was no suppuration and no fistulæ, and while I could not pass a very small filiform, it might have been done after rest in bed, hot fomentations, and the usual preliminary treatment in such cases. My previous success with suprapubic puncture, however, rendered me optimistic about the case, and I felt convinced that the simplicity of the operation made it by far the more conservative course to pursue. Local anesthesia with cocain was used. No difficulty was experienced, and a catheter was introduced and the skin and musculature sutured over it.

The only special precaution necessary in this operation is to see that the bladder is distended with urine before making the puncture, so that the peritoneum will not be endangered; but as relief from the pain of distention is one of the urgent symptoms for which the operation is primarily done, the risk of puncturing an empty bladder, and possibly injuring thereby other structures, is very small, even though no special attention is given the matter.

The danger of urinary infiltration or sepsis following prevesical puncture is reduced to a minimum; the small opening in the bladder made by the trocar, smaller even than the instrument itself since fewer fibers of the bladder wall are cut when that viscus is distended, than would be the case if empty, and hence a more complete closure of the opening following contraction, and, of course, less liability of leakage, which is made still more improbable by the dorsal decubitus, a position that should be maintained for forty-eight hours for this reason, and also to favor thorough drainage through the perineal wound or *per via naturale,* as the case may be.

I appreciate the fact that two cases, or two dozen, would be inadequate from which to deduce conclusions ordinarily, but the opportunities for treating these cases are not numerous in one man's experience, and one case demonstrates as well as a hundred the principle involved, viz., the practicability of entering the urethra by means of a curved cannula.

Now it seems evident to me that the far greater simplicity with which this operation is done makes it much preferable to the more complicated section, which entails more trauma, loss of time, danger of infection and requires more skill in performance and trouble in after-treatment, except, perhaps, in the rare cases complicated by cystitis of so severe a type that suprapubic drainage is necessary. The number of such cases, however, that can not be more successfully drained through the perineum is very small, the dependent position of the latter route making it more effective for the purpose.

I believe the time for groping in the dark in the attempt to enter the bladder by means of the Cock operation, or even Wheelhouse's method, is at an end, the internal guide so easily obtained by simple puncture, so simplifying the cases as to render the more difficult methods undesirable. To those who practice eustachian catheterism this will be perfectly patent, since the technic of the procedures is strikingly similar, the cannula representing the narial passage and the entrance to the urethra the eustachian meatus; retrograde catheterism of the urethra by the cannula is, however, much the easiest of performance, being but little more difficult than the now obsolete method of female catheterism without sight. Of course, cases admitting even the smallest filiform without too much delay in preparation afford the necessary guide and are readily dealt with by the Syme operation. I would only enter an earnest plea for the frequent adoption of retrograde catheterism in cases of impermeable stricture by the suprapubic puncture method, since it has, in my hands, converted a formidable and difficult operation into one of simplicity and ease.

---

**Sudden, Non-Traumatic Blindness.**—Laquer observed in 5 cases during the last six months sudden blindness from a different cause in each. In one it was the result of hemorrhage into the vitreous from a vascular affection on a basis of albuminuria. The prognosis was deemed to be unfavorable and the results confirmed this assumption. In other cases the cause was embolism, or retrobulbar neuritis, anemia from prolonged hemorrhage or preretinal hemorrhage. The embolism in the central artery was correctly diagnosed as the ramifications of the lower branch of the artery were nearly obliterated when first seen eleven weeks after the blindness had suddenly developed. No other cause could have reduced their diameter to such an extent in such a brief space of time. Treatment was ineffectual. The prognosis was announced as favorable in the case of retrobulbar neuritis on a probably rheumatic basis. The improvement under the salicylates and the gradual return of the primary pupil reaction before vision was restored corroborated this view. The patient was a young girl who had suffered from rheumatic pains in arms and shoulders. She took in all 60 gm. of potassium iodid in about two months. The blindness had come on suddenly and was complete, but vision was completely restored in two months. In another case a young girl "took cold" returning home from a ball in winter, and the next day she could scarcely see with one eye, the disturbance increasing to nearly complete loss of vision. Recovery was obtained in this case likewise in the course of two or three months under sodium salicylate for a few days followed by potassium iodid. In still a third case he witnessed restoration of vision after unilateral blindness from retrobulbar neuritis, although a year elapsed before the patient was entirely cured. In the case of loss of vision in one eye from anemia the blindness was permanent, and Laquer remarks that he never knew a case of this kind to terminate otherwise. His article is published in the *Klin.-therapeutische Wochenschrift* X, No. 23, 1903.

SATURDAY, JANUARY 9, 1904.

### DEATHS OF THE YEAR 1903.

In THE JOURNAL of Jan. 10, 1903, were noticed the deaths of 1,400 regular practitioners in the United States. During 1903 the deaths of physicians in the United States and Canada numbered 1,648.* This is probably within 5 per cent. of the total mortality in the medical profession of North America. The number of physicians in this country can only be estimated, we are sorry to say, but a close estimate would place the number at 120,000.

In 36.6 per cent. of the cases no cause of death was given or the cause alleged was incorrect or incomplete. Heart disease, which undoubtedly includes a number of cases of sudden death and cases of so-called "heart failure," was given as the cause of 163 deaths; pneumonia stands first among the legitimate causes of death, with 109; tuberculosis caused 89 deaths; nephritis 84 deaths; paralysis, which is relatively indefinite, is reported as having caused 96 deaths; apoplexy, another relatively incorrect term, 60 deaths. Accidents of various kinds caused the death of 71 physicians. Of these, 8 were due to drowning, 16 to falls, 11 to poison, 5 to burns, 5 to runaway accidents, 14 to railway accidents, and 4 to street-car accidents. Nine physicians were murdered; there were 24 suicides and 1 case of justifiable homicide. Among other principal causes of death are typhoid fever, 48; septicemia, 21; appendicitis, 26; cancer, 27; angina pectoris, 18; diabetes, gastritis and rheumatism, each 10; meningitis, 16, and uremia, 15.

Of the 1,648 deaths of the year, 147, or 8.9 per cent., were members of the American Medical Association. The extreme limits of age were 21 and 101, 2 deaths occurring at the former and 1 at the latter age. The maximum of deaths occurred at 65, at which age 47 physicians died. Next come 60 and 78, with 36 deaths; 62, with 35 deaths; 70 with 34 deaths; 75, 73 and 45, with 33 deaths. Above the age of 90, 15 deaths occurred.

The years of practice varied from the first to the seventy-fifth year. In 181 cases, or 11 per cent. of the total, the length of practice was not stated. The greatest number of deaths occurred in the twenty-fifth year of practice, in which 51 were recorded. In the twenty-eighth year, 40 were noted; in the thirty-third year, 39; in the twentieth and thirty-seventh years, 37; in the twenty-first year, 36; in the thirty-fifth year, 30; in the twenty-ninth and twenty-fourth years, 32; in the nineteenth, twenty-fourth and twenty-ninth years, 32; and in the twenty-seventh year, 31, and in the thirty-sixth and forty-fifth years, 30. Of the entire number, 209 physicians had practiced more than half a century, and 2 had been in practice seventy-five years at the time of their death. During the year of graduation, 8 physicians died; in the first year thereafter, 15; in the second, 20, and in the third, 16.

The annual death rate per thousand for 1903, based on an estimate of 120,000 physicians, was 14.42, a rate lower than that of most great cities. This goes to substantiate our statement of last year that notwithstanding the risk of disease and exposure to which physicians are unusually subject, they lead a relatively sanitary life and practice what they preach.

### SUBPHRENIC ABSCESS.

Many conditions which when first described are looked on as of interest merely from a diagnostic or pathologic standpoint, later when more fully understood are frequently treated surgically with success. Collections of pus beneath the diaphragm offer a very good example. It is only within the past few years that such cases have been at all frequently reported, and up to within a short time it has been rare to see a report of more than two or three operations for this trouble by one surgeon.

A report of sixty cases operated on by Körte of Berlin in his private practice and service at the urban hospital during the past twelve years, would indicate that the condition is relatively frequent and that patients are sometimes allowed to die from lack of surgical treatment because the condition is not recognized. Grüneisen[1] gives abstracts of Körte's series of cases, and some very interesting facts which may be deduced from an analysis of them. Regarding the etiology of this condition, he finds that the infection most frequently originates from the vermiform appendix; perforating ulcer of the stomach or duodenum also occasionally causes the trouble and among the less frequent causes are abscess of the pancreas or liver. The infection may also find its way into the subphrenic space from above in disease of the lower ribs, the pleura or the mediastinum. The clinical picture varies according to the pathologic condition giving rise to the abscess. In most cases the first symptoms are those of localized peritonitis. Pain is not a constant symptom, neither is absence of fever evidence of the non-existence of abscess. Physical examination often gives characteristic signs early; the bulging of the lower part of the thorax and increased area of dullness in the region of the liver are important signs, and if the abscess contains gas there is usually a tympanitic zone between lung resonance and the liver dullness below.

---

* During 1902 the deaths of regular physicians only were recorded, during 1903 those of eclectics and homeopaths were included.

[1] Archiv für klinische Chirurgie, 1903, vol. lxx, p. 1; THE JOURNAL, xli, p. 583, title 26.

In many cases a definite diagnosis is impossible; for example, in certain cases of encapsulated basal empyema or liver abscess. Exploratory puncture is not without danger, but it is considered justifiable in case preparation is made for immediate radical operation if pus is located. The prognosis is favorable if an early diagnosis is made and pus freely evacuated; 40 out of the 60 cases were saved by operation. The abscess may be evacuated either by incision at the costal margin in the epigastrium or in the lumbar region, or by the transpleural route after resection of one or more ribs. The last-mentioned operation is best adapted for free drainage in the majority of cases. Frequently there are adhesions between the diaphragmatic and parietal pleura. If not, it is thought wise to suture the two layers of the pleura before evacuating the pus. In still other cases infected fluid in the pleural cavity or even empyema may co-exist, in which case the abscess and the pleural cavity are drained through the same opening.

This is probably the most valuable contribution that has appeared on this subject, and the large number of cases reported in the experience of one surgeon emphasizes its importance. Comparatively few cases have been reported in America, though we doubt if any surgeon of wide experience has failed to see at least one or two. No doubt a considerable number of lives are sacrificed every year because such conditions are not promptly recognized and treated, and anything which brings the knowledge of more obscure conditions promptly before the profession is of importance. A great service has been rendered to the profession by those of its members who have laboriously collected statistics of scattered cases by many operators in various parts of the world, published in many different languages. These collected statistics, however, are not as valuable as the wide experience of one competent observer and operator. The careful tabulation of 179 cases of subphrenic abscess by Maydl will be remembered by many who have been following surgical literature, and for a number of years practically all of our definite knowledge has been based on this tabulation. Körte's personal experience in over one-third as many cases as Maydl tabulated from all literature gives us much clearer information on many points and shows how greatly the death rate may be reduced in the hands of a competent operator. Maydl's statistics give 50 per cent. mortality in this condition. Körte's mortality is only 33 per cent.

---

## WHY SCIENTISTS ARE POOR WRITERS.

"A Plea for Better English in Science" is made in a recent number of *Science*. The writer has passed judgment on about 100 manuscripts submitted by scientists, and decides that but 19 per cent. are good, 57 per cent. fair, and 24 per cent. are poor. Of these authors, about 75 per cent. have had collegiate or university training, and no fewer than 20 of them are now professors or instructors in leading universities and schools of science. Yet most of these 20 are placed in the "fair" class, and some even "poor." "Thus it appears that scientific and university life, with the preparation in lower schools which this implies, does not insure good English." This deficiency is ascribed in large part to neglect, the ability to write clearly and forcefully is considered as lying dormant, lacking a stimulus properly directed to bring it to light. If this is the case, then our universities are woefully deficient in applying stimuli, for it is indeed questionable if better ability to use our pliable language is to be found among those whose scholastic education continued beyond the high school than among those who stopped at or short of that point, but who subsequentlyy have occupied similar places in life. The collegiate instruction can enable the student to fight shy of the split infinitive, and to appreciate the horrors of the terminal preposition; but it can not often succeed in enabling him to write readable letters, much less interesting ones, if he could not already do it before his matriculation papers were filed. Writers are surely among those who are born and not made, and the correct use of English that can be acquired bears little relation to the forceful and attractive writing of which many of little education are capable. But why should scientists so often be poor writers and so seldom forceful, not to say entertaining?

We contend that something more than mere chance or simple carelessness is involved. Is it not that the very nature of his thought and work and the exacting requirements of scientific precision of expression, by themselves annul much of any natural trend towards pleasing use of language? Can a man be expected to have much left in the way of attractive expression after writing results of researches on meta-diazo-xylene-sulphonic acid, or what not, for several years? Is the description of the arrangements of the fibers in the dorsal roots of the lumbar plexus of *Mephitis mephitica* conducive to scintillating epigram? We are inclined to believe that a naturally brilliant writer will become more or less prosy after taking notes and writing theses on most of the topics that are open for research. Opportunities are now few for broad generalizations to which force can be given by figures of speech. May this not be the reason for the frequent complaint about the absence of literary ability in the general run of medical papers? Let us take the case of a young man stimulated to appreciate the poetic in nature and to reproduce it in his writing, by his first teacher of "English literature and rhetoric." He begins the study of medicine, and promptly his literary efforts are restricted to answering "eight of the following ten questions" in two hours. Osteology touches few poetic chords, and even the aroma of urinalysis fails to induce anything graceful in the "possible sources of error in the tests for albumin." Myology, angiology, et al, are as little inspiring, except for the production of

"On old Minerva's peaked tops," etc. Perhaps in physiology or pathology there appears something to warm the fast waning fires of poesy, but there is little opportunity for literary effects in a sheet of pink examination paper. If, perhaps, the struggle of the leucocyte and the bacterium appeals to him as Homeric, and he refers to a scar as "the monument to the martyred leucocytes erected by the grateful tissues they have saved," some hard-headed instructor will probably blue-pencil "Prolix" across the ode.

The author of the article in *Science* appeals to scientific men to cast off their indifference to the beauties of language, and to devote to their writing some of the energy they manifest in research. We fear, however, that the trouble does not lie merely in a lack of volition, but rather in the very tendencies of research itself; and as this tendency appears to be essential to exactness, its influence will not be easily overcome. Only occasionally can we expect a man with the innate genius to pass through this influence and to come out with the ability to be scientifically exact and at the same time brilliant in expressing himself. There are few men who can stimulate us with apt references to Sydenham's big toe. or Benjamin Rush's purgatives without being either absurd or tiresome. Such a talent is not the product of education or intention alone.

## THE PATHOLOGIC ANATOMY OF PARATYPHOID FEVER.

Some time ago[1] we called attention to the class of cases whose symptoms, although they clinically resemble typhoid, are caused by a group of organisms standing between the typical colon and typhoid bacilli in cultural characteristics. This group of organisms shows among its individual members slight cultural differences, no greater than those between various strains of colon bacilli. Because of its intermediate position the organism has been variously designated as the "paracolon" or the "paratyphoid" bacillus. The results of the infection have also been various, the organism having been found sometimes in local abscesses, sometimes with pyemic manifestations, and often with a clinical picture very similar to that of typhoid fever. Therefore, it would seem justifiable to make a distinction on clinical grounds and to separate cases that resemble typhoid from those that do not, even if the infection is by similar organisms, the first class of cases being referred to as "paratyphoid fever"; the other by the general term of paracolon infection, or, for specific cases, as "paracolon pyemia," etc.

Paratyphoid fever, on this basis, while much like true typhoid, offers in any series of cases some slight differences in that the course is usually milder, and that diarrhea and hemorrhages are less frequent, although severe hemorrhage from the bowel occasionally occurs. Of course, the most suggestive feature is the absence of the Widal reaction when the patient's serum, diluted as high as 1 to 40 or more, is used against true typhoid bacilli. Any case with fairly conclusive clinical evidences of typhoid that does not give the agglutination reaction should be looked on with suspicion as possibly being *paratyphoid*. As there are differences in the agglutination reactions among the different members of the group, a negative result when the agglutination test is made with known cultures of paracolon bacilli is not at all conclusive evidence that the case is not paratyphoid, so the most reliable method of diagnosis is by all means the securing of blood cultures.

Because of the infrequence of fatalities the anatomic condition present in this disease has not been studied to any extent, and it has been an open question whether it did or did not resemble true typhoid closely. There are now, however, five recorded autopsies in cases with the clinical and bacteriologic features of paratyphoid fever, and as there is a fair degree of correspondence between them, Wells and Scott,[2] who report the fifth case, consider that they afford a good idea of the usual anatomic picture. It would seem that the differences from true typhoid are anatomically quite marked, despite the clinical resemblance and the occurrence of bowel hemorrhages. In fact, the lesions are much more like those of simple septicemia than like typhoid. The only constant feature of the five cases is splenic enlargement, which is similar to that of all the fatal bacteriemias, including typhoid. On the other hand, the lymphatic apparatus of the alimentary tract, including Peyer's patches, solitary follicles and mesenteric glands, is entirely free from swelling or the other changes so characteristic of typhoid. In two of the five there was no ulceration; in one a very slight superficial necrosis, and in two shallow, dysentery-like ulcers of the intestine. These did not in any case resemble the ulcerations of typhoid, not involving the Peyer's patches and being without the usual swollen margins. Microscopically the differences are even more marked, for there is none of the proliferation about the ulcers and in the lymphatic structures that characterizes typhoid, and in fact the borders of the ulcers present no evidence of reaction of any kind. Focal necrosis in the liver and parenchymatous degeneration of the kidneys constitute practically all the remaining lesions, so it will be seen that the anatomic changes are not great, and also that there is nothing characteristic about them. Similar pictures may be produced by other organisms causing fatal septicemia, and it is possible that some of the cases that have been reported as typhoid without intestinal lesions have been really paratyphoid. It is indeed remarkable that two organisms producing such similar clinical manifestations and with general biologic peculiarities so nearly alike that their separation is by no means easy, should exercise such different effects on the body, one apparently without action on the intestinal lymphatic structures which receive the brunt of the attack of the other. One is reminded of Welch's hypothesis of the production of specific cellular toxins by bacteria against the cells of their host. The geographical distribution of the five fatal cases—Santa Cruz, Prague, Roumania, Philadelphia and Chicago—indicates that the paratyphoid organism is as widely distributed as the true typhoid bacillus.

### THE INFLUENCE OF BURNS ON THE ANIMAL ORGANISM.

While it is recognized that the animal organism can be subjected to moderate elevation of temperature, for not too long a period, without directly deleterious effects, it is equally appreciated that there is danger from great elevation, particularly if long continued. It is believed that, in consequence of the latter, changes take place in the blood and the other tissues incompatible with the maintenance of life. Such changes must occur, at least locally, in exaggerated degree in burns, and a more intimate knowledge of the processes resulting under such circumstances may throw light on those attending the febrile state.

Among the phenomena that have been observed in the sequence of burns of the surface of the body are morphologic alterations in the red blood corpuscles, even to the point of complete destruction; escape of the hemoglobin of the erythrocytes into the blood plasma; partial formation of small thrombi, causing ulceration, for example, in the intestine; alterations in the cells of the nervous system, the uriniferous tubules, etc. In the belief that cytotoxins must play an important part in the development of these phenomena, von Dieterichs[1] undertook a series of investigations on animals, to determine whether, in connection with burns of the surface, autolysins and autoagglutinins, isolysins and isoagglutinins, and heterolysins and heteroagglutinins are present in the blood, and in what proportion. He reasoned from existing knowledge that specific fixators (intermediary bodies, amboceptors) appear and unite with non-specific cytases (alexins, complements) always present in the blood serum, and form cytotoxins, which, on the one hand, cause agglutination of the red blood corpuscles, with the development of their hemolysins, and, on the other hand, possess cytotoxic and cytolytic properties for various cells of the body. As a result of his observations, he has reached the conclusion that elevation of temperature gives rise especially to complete or partial destruction of the cellular elements of the blood and the tissues. This is followed by the formation and accumulation of cytotoxins (hemotoxins) in the organism, which are injurious not only to the cells of the body itself (autotoxins), but also to the cellular elements of other animals of the same species (isotoxins), although in lesser degree, and also for animals of another species (heterotoxins). The formation of the cytotoxins of the blood takes place probably with especial activity during the first five or ten hours after the inception of the burn, and then gradually diminishes. As endeavors to render the serum inactive by exposure to a temperature of 57 C. for twenty-five minutes yielded a positive result, it can be assumed that the hemotoxins formed as a result of burns also consist of two parts, a specific fixator (amboceptor of Ehrlich) and a non-specific cytase (complement), which is readily destroyed by the action of various agents. In addition to hemolysins, there appear in the blood of animals agglutinins, whose action appears later than that of the bodies already mentioned. To their action are due the emboli and thrombi found after death.

The changes in the blood after burns are fully explained by the formation of hemolysins and hemoagglutinins. The presence of other cellular poisons may be suspected in the organisms of burned animals, whose specific effects on cellular elements of a definite kind can be compared with the action of the hemolysins and hemoagglutinins on the elements of the blood.

### THE IMPORTANCE OF RESISTANCE TO TUBERCULOSIS.

Dr. Sims Woodhead's Phipps lecture[1] on pulmonary tuberculosis is notable for its optimistic utterances as to the curability of the disease, and as to the importance of germs as compared with the importance of a body capable of resisting disease. Dr Woodhead's own experience shows that in a very large proportion of lungs of old people dying from other causes than tuberculosis, there were gross macroscopic evidences of the former occurrence of the disease, and probably had his examination been as minute as those of Naegeli, a still larger proportion might have been found. He says he has handled, inspired and probably ingested tubercle bacilli for many years, and yet he has not tuberculosis. It is the soil, not the seed, as has been stated many times by others; the defense, not the extirpation of the germs, on which we must place the most reliance in our conflict with tuberculosis. This, of course, does not imply that the active fight against the infection is to be neglected or that the extirpation of the germs is not also an object, but it should not be the sole aim in our treatment of the condition.

### THE JOURNAL OF INFECTIOUS DISEASES.

We have received the first issue of the above journal—a unique publication, in that it is, so far as we know, the only medical journal that is endowed. It has been established in connection with the Memorial Institute for Infectious Diseases, founded by Mr. and Mrs. Harold McCormick, but the journal is specifically endowed independent of the institute. As its name indicates, it is to be devoted to the publication of original investigations dealing with infectious diseases, their etiology and prevention. It will have a special field to itself, and we are told that only such contributions as bear directly on the topics indicated will be published. "The biology and chemistry of the various pathogenic micro-organisms, the physiology and anatomy of the morbid processes that they initiate, and the hygienic and sanitary problems to which they give rise are considered to be especially within the scope of the undertaking," is from the announcement contained in the first number. The first issue contains eleven original contributions, and consists of 210 7x10 pages, single, wide columns, and is printed on excellent paper. Typographically, the journal is excellent. The illustrations, made on heavy glazed coated paper, come out remarkably well. The journal is under the editorial management of Drs. L. Hektoen and E. O. Jordan, and Drs. Frank Billings, F. G. Novy and W. T. Sedgwick are named on the title page as associate editors. The journal will be issued at irregular intervals, as rapidly as the amount of material warrants, each volume to contain 500 pages. The subscription price is $5 per volume. The medical profession of the United States is to be congratulated on this further evidence of the interest that rich men are taking in scientific medicine, and especially on the fact that it will carry to the old world another proof that this country is doing at least its share in the progress that is being made in scientific medicine in the twentieth century.

---

## THE PROPOSED POST-CHECK CURRENCY.

The inconvenience attendant on sending money by mail will be greatly lessened if the post-check currency bill, introduced into Congress by Mr. Gardner of Michigan, becomes a law. The bill contemplates the issue of the present United States $1, $2 and $5 paper currency with blank spaces on which may be written the names of the sender and the payee. So long as these spaces are blank the bills will pass current as do the present greenbacks. A person wishing to send money by mail will affix and cancel a one- or two-cent stamp, and then will write his name and the name and address of the one to whom he wishes to send the money. Then the bill may be placed in an envelope and mailed without more formality or trouble, and the bill becomes payable only to the person named on its face. The recipient can redeem it at any postoffice or bank; after which it is not reissued. A further proposal is to issue fractional currency of denominations of 5, 10, 25 and 50 cents, but this is a separate matter. The whole plan is so delightful in its simplicity that to mention it can only be to commend and to compliment the inventor, Mr. C. W. Post. Of course, it will be impossible to send $1.63 by post-check currency, there being no bill for that amount; but when the proposed bill has become a law, we shall have taken a long step toward the easy transmission of money by mail. It will be seen at once that if bills are issued on this plan there will be a cleaner lot of paper money, and it is especially to be advised for this reason alone. But physicians and all who send money by mail will find it a great convenience.

## THE IROQUOIS THEATER FIRE.

The awful theater disaster at Chicago December 30, which has stirred the country more than any other recent event, has in it many lessons which it is to be hoped will be utilized against future accidents of the kind. The most pitiful feature of the case is that it occurred during the holidays when the city schools were not in session,[1] and thus a larger proportion of the audience were women and children than is usually the case, even at matinees; and such an audience is naturally less self-helpful and resourceful than one composed of adult men. Many of the victims were trampled down and smothered, as the absence of burns on their bodies testified. It is doubtful, however, whether this wild panic, in which so many lives were sacrificed, could have been absolutely avoided, even had the crowd attempted to go out quietly and orderly. There would have been a certain loss of life from the draught of the flames into the upper galleries, but that the loss of life should have been so great in a building supposedly fireproof and which is left so little structurally injured after the event, is one of the striking features of the case. The greatest lesson which the holocaust teaches us, however, and which we think should be most of all considered, is that under no circumstances could all those in the upper galleries have escaped through the narrow exits provided. No theater that is inclosed by other buildings, as is the Iroquois, and that has heavy walls with few and narrow openings, can be considered safe. Every theater should have ample exits on at least three sides, so that in a panic every part of it can be emptied in a few minutes. The exits should be so made that under no circumstances could they remain closed against pressure from within. If this lesson is properly learned, we may hope for no recurrence of such a holocaust as that of Chicago. Panics may occur—we can not insure against them—but their consequences will be less disastrous. Automatic sprinklers, steel and asbestos drop curtains and every other appliance against fire should be provided as well as plenty of aisle space, but all these are as nothing compared with ready and ample means of exit. Regardless of the amount of danger or the cause of fright, there is no greater cause of panic than the failure of the audience to see abundant avenues of escape. Thousands of lives have been sacrificed on a false alarm of fire, and will be again if provision is not made for the panic of the multitude.

# Medical News.

## ILLINOIS.

**Physician's Estate Sued.**—Dr. Jeremiah H. Stealy, Freeport, has sued the estate of the late Dr. W. S. Caldwell for $18,000 alleged to be due him for extra services performed while Dr. Caldwell was taking a trip around the world.

**Sanitary Inspection of Cities.**—The State Board of Health announces that instead of seventy-five cities inspected, as reported in The Journal of last week, one hundred cities have been covered by the sanitary inspectors of the board.

**Smallpox Called "Itch."**—Because of an epidemic of mild smallpox, which is called "itch," the Cottonwood school, Champaign County, has been closed.——The quarantine established by Shawneetown against Ridgway has been lifted, by order of the State Board of Health.

**Personal.**—Dr. Guy G. Dowdall, Clinton, has been appointed division surgeon for the Illinois Central Railroad, vice Dr. John M. Wilcox, resigned.——Dr. Henry Richings, Rockford, on March 4, will celebrate the fortieth anniversary of his entry into practice. The Winnebago County Medical Society intends to hold its annual banquet on that date with Dr. Richings as the guest of honor.——Dr. George W. Parker, Mount Sterling, and wife have sailed for Europe, where they expect to remain two years.

---

[1] Among the dead were 38 teachers and 96 pupils of the Chicago public schools.

## Chicago.

**Will Have Its Own Training School.**—Cook County Hospital announces that it will soon establish a training school for its own nurses.

**Mortality of the Week.**—Not including those killed in the Iroquois Theater fire the dead of the week ended January 2, number 604, an annual death rate of 16.18 per 1,000. Pneumonia, as usual, leads with 146 deaths; consumption had 56, and Bright's disease 52 deaths.

**Deaths of the Month.**—During December 2,354 deaths were reported, a death rate per 1,000 of 14.69. (This does not include the fire victims.) Pneumonia leads with 498 deaths, consumption comes next with 228, and violence and Bright's disease are each credited with 166.

**Personal.**—Dr. P. Maxwell Foshay, Cleveland, whose marriage is announced in another column, will, we understand, locate in Chicago, early in April, and will be resident medical director of the new branch of the Mutual Life Insurance Company of New York, which has recently been opened there.——Dr. W. Harrison Hipp has been reappointed a member of the State Board of Health.

**The Deaths of 1903.**—Including the 587 deaths in the Iroquois Theater fire the Department of Health reports that the total deaths for 1903 will number 28,940, instead of the 28,353 given in the statement of mortality for the year. This will increase the death rate from 15.04 to 15.35 per 1,000. Deaths from violence were already more than 12 per cent. in excess of the average for the period since the census year 1900; but these 587 theater deaths swell the excess to 41.5 per cent. over the yearly average of violent deaths. Even with this addition to the total mortality, the death rate is 6 per cent. lower than the yearly average since 1892, although it is 8.2 per cent. higher than that of 1901 and 5.3 per cent. higher than that of 1902.

**Effects of One Milk Delivery A Day.**—In the Bulletin of the Department of Health the effects of the arbitrary action of the milk dealers is thus characterized:

> The disastrous effects on child life—threatened by the barbarous action of the milk-wagon drivers in refusing to make more than one delivery of milk a day—were largely overcome by the relatively cool weather of the summer, by unusual effort in milk inspection (including the employment of an emergency corps of inspectors, known as "milk scouts"), and by an enormous development of the sterilized milk service fostered by the Woman's Club and Hospital Association.
>
> As a matter of record the mortality of infants and young children during 1903 was lower than ever before known—8 8 per cent. less than in 1902, 9.4 per cent. less than in 1901 and 57 per cent. less than the average of the period between the two census years, 1890 and 1900. In 1891 the deaths of children under 5 years of age numbered 110.38 in every 10,000 of population; in 1903 they were only 41.7.

## MARYLAND.

**Insane Hospital Report.**—According to the annual report of the Maryland Hospital for the Insane, No. 1 at Springgrove, 631 patients were in the institution during the year ended October 31; 33 patients were discharged and 40 died. There were 79 new admissions. The number of cases due to alcohol is increasing. The institution needs additional land for farming purposes and an isolation building for infectious and contagious diseases, especially consumption.

## Baltimore.

**Banquet to Health Commissioner.**—The third annual banquet tendered by the health department to Health Commissioner Bosley, was held December 28. Quarantine Physician Heiskell acting as toastmaster.

**Woodhead in Baltimore.**—Dr. German Sims Woodhead, professor of pathology at the University of Cambridge, England, spent December 31 in Baltimore. He was the guest of Drs. Osler and Welch and spent several hours inspecting the Johns Hopkins Hospital.

**Disease on Increase.**—Scarlet fever and diphtheria are both prevalent and on the increase. The health commissioner finds it necessary to draw public attention to this fact. He thinks people are becoming careless and no longer fear scarlet fever. Many neglect to report its presence.

**Senses Hospital Report.**—The South Baltimore Eye, Ear and Throat Hospital reports since the opening, May 1, 1901, 1,323 patients have been treated, 56 of whom were house patients. In the dispensary there were 6,219 visits and 358 surgical operations. The expenses were $1,229; receipts, $1,136.

**Isolation Hospital Needed.**—The necessity of an infectious diseases hospital will again be agitated. A year ago a site was purchased in the suburbs by a commission of which Dr. Welch was chairman, but the residents obtained a legislative enactment forbidding the erection of the institution within a half mile of any of the parks. A suit is pending regarding the validity of that purchase.

**Medical Agency a Success.**—The City Medical Agency in South Baltimore having proven a success, a second one will be established in Northwest Baltimore. A male and a female physician are employed at each, and it is designed to cover the whole city. The addition to the Bayview Hospital a city almshouse of over 150 acres gives the city opportunity for great increase in facilities for caring for the sick. A house bought with the new land is being prepared as a hospital for female consumptives, and a contract has also been signed for a house to hold 70 male consumptives. The officials have visited New York to examine the methods there in vogue by tents and pavilions with the purpose of increasing the number of consumptives who can be cared for on the high and extensive grounds of the new farm. The supervisors are also laboring for an improvement in the nursing service and care of the insane.

**Deaths and Births in 1903.**—The health commissioner reports in 1903, 10,141 deaths, 30.59 per cent. being under 5 years of age. There were 8,620 births reported. It is noticeable that a considerably less number of white females were reported born and dead than white males. It is strange that this disproportion is not seen in the case of colored births and deaths. The annual birth rate was 16.17 per 1,000—namely, whites, 15.52; colored, 19.74. The annual death rate is less than any of the three previous years. The following are some of the causes of death: tuberculosis, 1,366; pneumonia, 1,101; heart disease, 757; Bright's disease, 693; diarrhea, dysentery and enteritis, 658; apoplexy, 369; cancer, 370; accidents, 416; old age, 258; bronchitis, 235; typhoid fever, 189; diphtheria, 160; influenza, 92; scarlet fever, 84; measles, 77; suicide, 58; puerperal septicemia, 57; whooping cough, 64; septicemia, 35; erysipelas, 26; malarial fever, 18; homicide, 14, and smallpox 2.

## MASSACHUSETTS.

**Bequests.**—The will of Mrs. Mary D. Converse makes the following bequests: Women's Charity Club Hospital, $2,000; Malden Hospital, $2,500.

**To Have New Dispensary.**—Charlestown Navy Yard is to have a new dispensary, a two-story building of brick and stone, 50 by 50, and to cost $11,000.

**New Gifts for Crippled Children.**—At the dedication of the new building of the New England Peabody Home for Crippled Children at Hyde Park, December 29, an additional gift of 33,000 feet of land was announced from Mr. Robert Bleakie, who gave 28,000 three years ago.

**Care of Consumptives.**—The Boston Association for the Relief and Control of Tuberculosis has issued a small booklet, which is to be given to children in the grammar and high schools of Boston, containing advice regarding the care of consumptives and rules to avoid danger from the disease.

**Epileptic Hospital Report.**—The trustees of the Massachusetts Hospital for Epileptics at Palmer report an average of 410 patients cared for there during 1903 at an average cost per week of $4.55. New buildings will soon relieve the present overcrowded conditions. They urge immediate provision for the large number of epileptic children at present unprovided for in the state.

**Boston's Insane.**—Boston sent 482 patients to the State Hospital for chronic cases at Tewkesbury in 1903 and cared for 215 others in her own almshouse and hospital on Long Island. Boston insane hospitals are as usual overcrowded, 286 women at Austin Farm and 283 men at Pierce Farm and 25 are to be removed to state asylums. At Christmas 42 patients were allowed to visit their homes.

**Doubles Boston's Water Supply.**—On December 29 water was admitted to the new acqueduct from the Sudbury dam. By this route the water travels 13 miles to the Weston equalizing reservoir and thence seven miles more to the Chestnut Hill Reservoir, whence it is distributed to the Metropolitan District of Boston. The new waterway has a capacity of 300,000,000 gallons per day and doubles Boston's water supply.

**Brigham Will Sustained.**—The decision of the U. S. Circuit Court sustains the will of Peter Bent Brigham and releases nearly $5,000,000 for the construction and maintenance of a hospital for the sick poor. He died May 24, 1877, leaving a large estate to be held in trust for twenty-five years. The corporation which has been duly formed may, therefore, forthwith proceed to the erection of such a hospital to be called the Brigham Hospital, the only restriction being that it shall be for the sick poor resident in Suffolk County.

**Investigation Committee Disagrees.**—The investigation of the Long Island Hospital by the city government of Boston has resulted in a disagreement in the committee. The majority, as was expected, finds many of the charges sustained. The minority completely exonerates the management. The move was a political one, with the purpose of finding excuse for a petition to the state legislature to abolish the unpaid board of trustees and substitute one paid commissioner. The present trustees have emphasized the hospital idea, have employed a medical superintendent, established a training school for nurses, employed a pathologist, etc., for all of which they are criticised in the majority report.

**Hospital Staff Changes.**—On January 1 Dr. Edward Cowles retired as superintendent of the McLean Hospital for the Insane at Waverly, where he has been since 1879. His first assistant, Dr. George T. Tuttle will become superintendent and Dr. E. Stanley Abbot, now assistant superintendent of the Boston City Hospital will take Dr. Tuttle's place, having practical charge of the women's side. Dr. Cowles will continue in consultation practice in Boston. Dr. Abbot was formerly assistant in McLean and returns there to devote himself to work in which he has already distinguished himself. Dr. Frank H. Holt will succeed him as assistant superintendent at the Boston City Hospital.

## MICHIGAN.

**Mr. Warren's Death.**—On November 11 Mr. William Matthew Warren, *general manager of Parke, Davis & Co., Detroit, died,* aged 39. He had been in the service of the firm for 22 years.

**The Test Case.**—In order to test the validity of the city ordinance requiring the filing of certificates of cause of death within 12 hours, Dr. Clarence B. Hernam, Grand Rapids, was recently arraigned for violation of the ordinance, pleaded guilty, and was fined $2 and costs.

**Communicable Diseases.**—Meningitis was reported present in November at 4 places; *whooping cough at 16 places;* measles at 31 places; smallpox at 53 places; diphtheria at 80 places; scarlet fever at 122 places; typhoid fever at 154 places, and consumption at 193 places. Meningitis was reported present at 4 places less; whooping cough at 3 places less; measles at 10 places more; smallpox at 11 places more; diphtheria at 3 places less; scarlet fever at 11 places more; typhoid fever at 31 places less, and consumption at 49 places less, than in the preceding month.

**Comparative Morbidity.**—For November, compared with the preceding month, influenza, pleuritis, pneumonia, erysipelas, whooping cough, measles and smallpox were more prevalent; and diarrhea, intermittent fever, inflammation of bowels, dysentery, remittent fever, cholera morbus and cholera infantum were less prevalent. For the same month, compared with the average for November in the last 10 years, smallpox was more than usually prevalent; and intermittent fever, erysipelas, inflammation of bowels, remittent fever, cholera morbus, whooping cough, measles and cholera infantum were less than usually prevalent.

**November Mortality.**—There were 2,623 deaths reported for November, or 1 death less than the preceding month. The death rate was 12.9 per 1,000 population. Important causes of death were as follows: Tuberculosis, 185; typhoid fever, 80; diphtheria, 112; scarlet fever, 14; measles, 7; whooping cough, 28; pneumonia, 206; cancer, 140; accidents and violence, 194. The number of deaths reported from typhoid fever was less than during October. Tuberculosis also showed a decrease, while diphtheria, scarlet fever and other diseases of children showed a considerable increase. There were no deaths from smallpox during the month, but one death from chicken-pox was reported.

## NEBRASKA.

**Police Surgeons Change.**—Dr. Stuart B. MacDiarmid, police surgeon, and Dr. F. J. Schieler, assistant, of Omaha, retired from office, January 1, and were succeeded by Drs. Isadore S. Trostler and Jay C. Decker.

**Personal.**—Dr. August F. Jonas, Omaha, who was operated on for gallstones by Drs. W. J. and C. H. Mayo, at Rochester, Minn., about a month ago, has gone to his former home, Madison, Wis., to complete his convalescence.

**Not Lepers.**—The sensational despatch from Lincoln announcing that there were 25 Russian lepers living in that city, has been investigated by the health officer and the city physician and declared to be totally without foundation.

**Vital Statistics of Omaha.**—For the first ten months of 1903, there were 1,764 births and 945 deaths in Omaha. There were 308 cases of scarlet fever, 71 of diphtheria, 106 of measles, 74 of smallpox, 70 of varicella, and 28 of typhoid fever, during the same period.

## OHIO.

**Fumigated During Vacation.**—By order of the Youngstown Board of Education, all the public schools of that city were fumigated during the Christmas vacation.

**Cincinnati District Physicians.**—The list of district physicians handed to the mayor as president of the Cincinnati Board of Health includes nine of the present staff, ten new appointees and leaves two vacancies to be filled later on.

**Typhoid Increasing.**—The health report of Cleveland for last week shows an increase in typhoid fever, of which 49 cases were reported, with 9 deaths. The total of cases was 121, which compared unfavorably with 5, the number for the corresponding week of last year.——At the state penitentiary, Columbus, the disease is said to be epidemic, 14 cases having been reported.

## PENNSYLVANIA.

**Railway Killed and Injured.**—From the report of the secretary of internal affairs, it is learned that, for the year ended June 30, 1903, 3,719 persons were killed, and 22,784 injured on the steam and street railways of Pennsylvania.

**Unusual Vaccination Location.**—A barber of Alliance is reported to have brought suit against Dr. F. W. Forbes for alleged malpractice, asserting that the latter applied vaccine to scratches which he had accidentally received on the face, and that the vaccine vesicle has appeared in this area.

**Union Meeting.**—A committee has been appointed by the county medical society to arrange for a meeting of the regular profession of the censorial district of the counties of Philadelphia, Delaware and Chester early in January. The meeting will be in the form of a reception to members of the county societies and invited guests.

**Officials and Nurses Exonerated.**—In the case of the death of a girl in the Pennsylvania Training School for Feeble-Minded Children, in which the father of the girl had made accusation of violent treatment as the cause of death, after thorough investigation of the case by the board of directors of the institution, they exonerate Superintendent Barr and the other officials and nurses from any blame in the case.

**Annual Meeting.**—The annual meeting of the Berks County Medical Society was held in Reading, December 8, when the following officers were elected: President, Dr. John F. Feick; vice-presidents, Drs. George Hetrick and James W. Keiser; recording secretary, Dr. Daniel Longaker; corresponding secretary, Dr. Hiester Bucher; treasurer, Dr. Irvin H. Hartman; reporter, Dr. William S. Bertolette; trustee, Dr. George W. Kehl; censors, Drs. Oan J. Thompson, Christopher H. Shearer and William E. Fisher; curator, D. S. Grimm, and librarian, Dr. S. Banks Taylor, all of Reading.

**Prosecution or Persecution.**—An interesting situation has arisen in connection with the prosecutions which have been carried on vigorously for some time by State Dairy and Food Commissioner Warren against dealers in impure articles. Judge Miller of Mercer County has refused to sentence those convicted in his court, holding that the action of the department is persecuting and lacking in equity. He holds that the dealers, not being expert chemists, should be warned, previous to arrest, and be given an opportunity to determine whether their goods are pure or adulterated. Dr. Warren proposes to make an effort to compel the judge to pass sentence in cases where conviction has been secured.

**Smallpox.**—An epidemic of "Cuban itch" is reported to exist among the school children of Essington. It is thought to have been brought by sailors to the port.——Smallpox has appeared among the inmates of the Lehigh County Poorhouse near Allentown. *Five inmates are reported to have the disease and* there are some suspects. The like institution of Blair County has to deal with the same disease. Two inmates have died and there are at least two other cases of the disease.——Smallpox has reached such proportions in Wayne County that Dr. Graff, a member of the State Board of Health, is said to have written letters of warning against the section to health authorities of surrounding regions.

**The Situation at Butler.**—At a special meeting of the Citizens' Permanent Relief Committee, December 30, it was decided to close the Philadelphia Hospital at Butler, January 15, as it is believed that the epidemic at Butler will have been controlled by that time. A committee composed of John H. Converse, Dr. French, and the mayor, is to prepare a testimonial to the nurses and physicians of this hospital, all having gone from Philadelphia, laudatory of their services.——The relief committee at Butler had received up to December 29 $45,000, and it was estimated that $35,000 would still be needed to relieve those in distress because of the typhoid fever epidemic. The ninetieth death from typhoid fever occurred January 3, and 3 new cases were reported on the same day.

### Philadelphia.

**A New "Pathy."**—J. B. Brown, a self-styled "cereopathic physician," has been committed to prison by Coroner Dugan. Brown had been treating a child, celery tea being a principal remedy. At the coroner's inquest on the death of the child, it appeared that Brown had no legal right to practice medicine.

**Want To Be Inspectors.**—On December 31 about 200 physicians took examination before the civil service board for the position of assistant medical inspector of the department of health. The corps of inspectors now numbers 13, but 45 additional inspectors were recently authorized. It was to fill the 37 additional positions that the examination was held.

**Scientific Societies Meet.**—On December 29, 30 and 31, the Association of American Anatomists, the Society of American Bacteriologists, and the American Physiological Society met in Philadelphia. Dr. Frederick G. Novy, Ann Arbor, Michigan, was elected president of the society of bacteriologists, and Prof. Charles S. Minot of Harvard University, president of the society of anatomists.

**Alleged Cruelty to Epileptic.**—Charged with cruelty to a patient in the insane department of the Philadelphia Hospital, two keepers, Richard Moore and Thomas McBlain, were held, December 26, by a magistrate, in $800 bail each for a further hearing. The victim is said to be an epileptic with homicidal mania, and is asserted to have received his injuries while being subdued into submission by his keepers, whom he had attacked.

**Lectures to Teachers.**—A part of the scheme by Director Martin for the inspection of public school children is that of lectures to the teachers so that they may better aid the inspectors in their work of detecting disease among pupils. Dr. Martin reports that he has asked the county medical society and the College of Physicians to co-operate in revising the list of infectious diseases which physicians must report to the board of health. Pneumonia, whooping cough, tuberculosis and measles will, perhaps, be added to the list.

**Smallpox and Typhoid Still Prevail.**—There is no abatement in the prevalence of smallpox and typhoid fever, as shown by the health report of the week ended January 2. There were 74 new cases of smallpox, with 11 deaths, and 150 new cases of typhoid fever, with 20 deaths. There were 83 new cases of diphtheria and 123 of scarlet fever. Pneumonia is prevalent, 95 deaths being ascribed to that cause. There was a high death-rate, deaths from all causes numbering 602, as compared with 554 for the previous week and 532 for the corresponding period of the previous year.

**Philanthropy.**—The will of the late Charles Hart, a lawyer, directs that the estate, valued at $56,000, be distributed, at the death of decedent's mother, to charitable institutions. Five thousand dollars each are bequeathed to the Children's Seashore Home for Invalid Children, at Atlantic City; the Children's Country Week Association; Sanitarium Association; Pennsylvania Training School for Feeble-Minded Children; Home for Incurables; Children's Hospital, and the Western Home for Poor Children.——The will of the late Hannah Adler, recently probated, bequeathes $2,000 to the Jewish Hospital for furthering the work of the Mathilde Adler-Loeb Dispensary.

**Parsimony Aids Disease.**—Dr. Seneca Egbert, professor of hygiene of the Medico-Chirurgical College, in a recent lecture before the Academy of Natural Sciences, stated that an urgent need in the schools and colleges is a comprehensive course in anatomy and hygiene and sanitation. One half of the population is under 24 years of age, and education of this portion in sanitary matters would have great weight in sanitary regulations. The great need of a city officer was pointed out, whose sole duty should be to go from school to school to look after the heating, ventilation, and general sanitary condition of the buildings. The parsimony of Pennsylvania, which appropriates only $6,000 a year for the care of the health of her citizens, results in the prevalence of smallpox and other contagious diseases.

**Dr. Woodhead's Lecture.**—On the evening of December 29 Dr. G. Sims Woodhead, professor of pathology of Cambridge University, England, under the auspices of the Phipps Institute of Tuberculosis, lectured on "The Paths of Infection in Tuberculosis and the Relations of the Tissues and Clinical Manifestations of the Disease." (See editorial in this issue.) A large number of stereopticon views were used to illustrate the subject. The lecture was a comprehensive, simple, direct presentation of the best knowledge on the subject. Many of Philadelphia's eminent physicians vied with one another to do Dr. Woodhead honor. The following acted as his hosts at various times for luncheon, dinner or reception: Drs. W. M. L. Coplin, John H. Musser, Charles H. Frazier, Charles F. Judson, M. P. Ravenel, and Horace Jayne

### GENERAL.

**Multiple Angiomata of the Spleen.**—Dr. William C. Pumpelly, pathologist to the pathological department of the Georgia State Sanitarium, Milledgeville, reports that in the necropsy on the body of a negro, female, who died from pulmonary tuberculosis, the spleen was found to be enlarged, and on section to contain a number of circumscribed hemorrhagic areas about 3 cm. in diameter and composed of blood vessels supported by a delicate connective framework not distinctly incapsulated but circumscribed and separate from the spleen structure. There were possibly twenty of these areas.

### CANADA.

Diphtheria is still very prevalent throughout the province of Ontario.

**La Grippe Prevalent in Toronto.**—A severe epidemic of la grippe exists in Toronto, and fifteen deaths a day were recorded in that city from pneumonia last week.

**Smallpox Prevalent in Cape Breton.**—The smallpox situation throughout the Island of Cape Breton is becoming very acute, and the local health authorities are strenuously endeavoring to check a general epidemic. In several districts the disease is rampant and fears are entertained that it may appear in Sydney.

**Personal.**—Dr. J. F. W. Ross, Toronto, is spending a two months' vacation in Egypt.——Dr. James Stewart, Montreal, has gone to Egypt to recuperate, after a long siege of blood poisoning.——Dr. W. F. Langrill, formerly medical health officer of Hamilton, Ont., has been appointed medical superintendent of the Hamilton General Hospital.

**Sanatorium By-Law Passes.**—The by-law to provide for raising $50,000 for a municipal consumption sanatorium in Toronto, was passed by the ratepayers at the annual municipal elections, January 1, by a vote of 4,071 to 3,822. All of the leading papers demanded its defeat in view of the good work performed by the National Sanitarium Association.

**McGill University Dental Course.**—The corporation of McGill University has decided to establish a dental department. The course will be four years of nine months each. The degree of master of dental surgery will be conferred at graduation, and not less than one year after graduation the degree of doctor in dental science may be conferred under certain conditions.

**New Laboratory for Queen's University.**—Queen's medical faculty has asked the Ontario government to establish in connection with that institution a branch laboratory of the Ontario Board of Health, for the examination of pathologic specimens. The government laboratory is now situated in Toronto, and it is claimed for eastern Ontario that it is too distant in securing prompt and effective results. It is likely that the government will grant the request.

**The Prevention of Tuberculosis.**—The Montreal League for the Prevention of Tuberculosis is issuing an appeal for funds to enable it to carry on the war against tuberculosis in that city. The league needs this money now for the purpose of establishing free consulting rooms, and intends as soon as possible to erect a sanatorium at Trembling Mountain, at which place the provincial government of Quebec has made it a grant of land for the purpose. The league is under the patronage of the governor general, Lord Minto, Lord Strathcona, Sir Louis Jette, and Sir William Macdonald. Senator Drummond is the president.

**Life Assurance Statistics.**—Dr. MacPhail of Montreal has been making observations as to the liability to earlier death of persons rejected by insurance companies, as compared with the liability of those accepted. In 5,115 applications, 409 were rejected; of these he traced 235, of whom during fifteen years only 31 died, while according to insurance actuarial figures, had the 235 been "sound lives," no less than 25 should have died in that period. Dr. MacPhail comes to the conclusion that those who are rejected by insurance companies, as a rule, manage to live about the usual average. The reason for this is that they take better care of themselves once they have been rejected.

### FOREIGN.

**German Anticharlatan Congress.**—The German Society for Combating Quackery has issued an appeal for a general congress to be held at Berlin January 14 and 15. Addresses on charlatans' practice and on the legal means of restricting it will be the chief features of the congress. The organization is in charge of Dr. Siefart, Charlottenburg, Hardenbergsstr. 39.

**Garre Goes to Vienna.**—Professor Garré of Königsberg has accepted a call to Vienna as successor to Gussenbauer. He is Swiss by birth and is now in his forty-eighth year, a pupil of von Brüns. He has occupied chairs at Tübingen, Rostock and Königsberg, and his name is well known from his numerous articles on almost all branches of surgery. He was at one time editor of the *Corr.-Blatt f. Schweizer Aerzte.*

**Drug Mistake at Bonn Gynecologic Clinic.**—A nurse administered to a patient at night two tablespoonfuls of a solution of zinc chlorid instead of the chloral which had been prescribed. Professor Fritsch writes to the *Deutsche med. Wochft.* that the patient vomited immediately, and milk and sodium bicarbonate were given at once and the stomach rinsed out. All danger was past in a few hours, and the patient well and free from pain. The only symptom left is a slight smarting when she swallows. He adds that the mistake was unpardonable and incomprehensible as the remedies for external use are kept in bottles with eight corners and fluted sides, while the internal ones are in smooth, round bottles and the two kinds are kept in separate places.

**The Prizes of the Paris Academie de Medecine.**—An unusually small number of the prizes were awarded this year. There was no competition for several and nothing of value was received for others. The Tremblay prize of $1,240 was bestowed on Albarran for his works on affections of the prostate, with honorable mention of others by Guiard and Petit. The Tarnier prize of $600 was given to Strohecker of Paris for a study of fibromata of the broad ligaments. J. Comby of Paris received the Roger prize of $500 for his series of works on children's diseases. The Vernois prize of $140 was divided between two laymen, P. Strauss and A. Fillassier, the former a senator and the other a lawyer, for their legislative work in matters affecting the public health, and F. Battesti of Bastia for studies on malaria. Other prizes were given to Arloing for his work on tuberculous ulcerations in the stomach, to Jousset for his method of diagnosing tuberculosis by "inoscopy." Also to G. Weiss for studies in medical electricity, to Bezançon and Griffon for bacteriologic studies on tuberculosis, to Philippe and Cestan for their studies on the mental troubles in sclerosis in patches, to Meige for his therapeutic study of tics, and G. Thibierge for a work on syphilis and deontology. The recipients were all French, with one or two exceptions, although competition is open to the world. Few if any contributions were received from outsiders. The communications above mentioned on which prizes were bestowed have all been reviewed in The Journal during the last year or two. The Académie has about fifty endowed prizes to bestow annually as has been described from year to year in these columns. Full details of the competition were given in The Journal of January 24, 1903. The Labordie prize of $1,000 for "notable advance in surgery," was not awarded this year.

**The Recipients of the Nobel Prizes:** *Finsen.*—Nyls Ryberg Finsen was born in 1860 on one of the Faröe islands, between Scotland and Iceland, and was educated at Reykjavik, Iceland, and later at Copenhagen. After obtaining his medical degree he was for some years prosector at the Copenhagen medical school, and commenced his studies on the influence of light on biologic processes at this time. His light institute was founded in 1896, but he is now unable to direct it personally, as he is confined to his room by a severe chronic affection. The International Medical Congress at Paris in 1900 was the first introduction of his methods of phototherapy to the profession at large. He has divided the sum received in the prize between his Light Institute and a hospital at Copenhagen. *The Curies and Becquerel.*—Professor Pierre Curie has occupied the chair of chemistry at the Paris Municipal School of Applied Physics and Chemistry since 1895, and has also had a chair at the Sorbonne since 1900. His wife, a Pole by birth, is now 35 years old, and took a degree as bachelor of sciences at Paris some years ago. She lectures at the normal school at Sèvres. The discovery of radium by this couple was preceded by the discovery by H. Becquerel of the light-emitting properties of uranium, and the Nobel prize for physics was divided between the three, all residents of Paris. *Arrhenius.*—The prize in chemistry was awarded to Arrhenius, a Swede, whose textbook on electro-chemistry is not only one of the most recent but also one of the most authoritative on the subject. His chief claim to distinction is his theory in regard to ions, which he advanced to explain the dissociation of substances by electricity. *Nationality of the Recipients.*—These prizes during the three years since they have been awarded have been distributed among nineteen persons. Although Nobel himself was a Scandinavian, not until this year has a prize been given to any of this race, but now Denmark, Sweden and Norway are simultaneously complimented. To date, 4 Germans, 5 Frenchmen, 3 Dutchmen and 2 Englishmen, 1 Russian and 1 Swiss have been the recipients of the five prizes for medicine, physics, chemistry, literature and promotion of peace. Those in charge of the awards seem to rank research and discovery above invention. The physics prize the first year was given to Röntgen, and last year to Lorentz and Zeemann of Holland, who first announced that optic phenomena could be influenced by magnetic action. Fischer was the recipient of the chemistry prize for his work on the synthesis of sugars, although it was far from recent.

### LONDON LETTER.

#### The Commission on Arsenical Poisoning.

The Royal Commission on Arsenical Poisoning, which was appointed in 1901, after the epidemic of arsenical poisoning due to contaminated beer, has at last issued a final report. Not only the question of contaminated beer but the whole subject of the contamination of food by arsenic was the subject of inquiry. It may be remembered that the epidemic in question was due to the use of brewing sugar (supplied by a single firm) which had become contaminated with the arsenic present in the sulphuric acid used in the conversion of starch into the sugar. The consequent inquiry led to several interesting discoveries. Another source of arsenical contamination was found: Malt is liable to contamination by arsenic volatilized from the coke used in the kiln. The commission have no doubt that arsenical poisoning from this source has occurred, and they describe a small outbreak of this nature which occurred last year at Halifax and was traced to arsenical coke. Reasons are given for the belief that such outbreaks were not uncommon in parts of the country where brewers habitually used malt dried over gas coke, but their true nature was not recognized until Dr. E. S. Reynolds showed the cause of the 1900 epidemic. It is not surprising that arsenic was not previously suspected because the quantity which by constant repetition has been found capable of producing illness is small, and the symptoms differ widely from those of acute poisoning. Beside beer, other articles of food may contain arsenic in the absence of proper precautions. Glucose is an ingredient of several foods in everyday use, and sulphuric acid is used in preparing a variety of food substances, such as table syrups, treacle and some kinds of vinegar. The report also draws attention to the frequent presence of large amounts of arsenic in glycerin, which is a common ingredient in cakes as well as in several mineral and coal-tar coloring substances used in the preparation of foods. The commissioners refuse to regard as negligible any quantity of arsenic in food, however small, as by due care it may be totally excluded. But for practical purposes, in view of the great delicacy of the available tests, they declare that the quantity present should not exceed 1/100 gr. of arsenic per pound, or in the case of fluids 1/100 gr. per gallon.

#### The London School of Tropical Medicine.

At the London School of Tropical Medicine Sir Patrick Manson delivered a most interesting address on the achievements and requirements of the school. He said that since it was opened on Oct. 3, 1899, over 300 students had passed through its portals. In the earlier days of the school's existance many of the students came for one or two months only. Now a large proportion of the students remained during the full course of three months. When they left the majority had a genuine practical grip of their subject. They had seen, and most of them had applied for themselves, the most recent methods of diagnosis, and as far as teaching and opportunity could insure they were qualified for medical work in the tropics —qualified both to practice their profession and to advance the science of tropical medicine. Where two or three men took a languid interest in tropical diseases some five or six years ago, a whole army of eager investigators had arisen, mainly composed of men educated or inspired by the London and Liverpool schools of tropical medicine. This multiplication of investigators had already borne remarkable fruit. Without alluding to what had been done in Liverpool he pointed out not a few notable triumphs by men from the London school. He instanced Dr. G. C. Low's work in connection with the etiology of elephantiasis; the practical experiment of Dr. L. Sambon and Dr. Low as to the spread of malaria by mosquitoes; the discovery in the Gambia colony of a new blood parasite, which was subsequently recognized as a trypanosoma by Dr. J. E. Dutton of the Liverpool School of Tropical Medicine, and the demonstration by Dr. A. Castellani, of the association of this parasite with sleeping sickness. Referring to beri-beri he did not despair of getting light on this disease. Dr. C. W. Daniels, the late superintendent of the school, had been placed in charge of the research laboratory at Kurla Lumpur in the Malay States.

### Ankylostomiasis in Miners.

In connection with the Liverpool School of Tropical Medicine, on Friday, Mr. Charles Salter delivered a lecture in the Thompson Yates laboratory of Liverpool University on "Ankylostomiasis in Miners." He spoke of his investigations in Westphalia and Belgium and of the measures adopted to eradicate the disease. If a miner, after leaving work neglected to wash his hands before eating, the disease could easily be conveyed, if the dirt on the hands contained larvæ. Expert opinion was divided as to whether the disease could enter through the skin. In his investigation the lecturer could not learn of any instance of workers above ground contracting the malady, except through contact with contaminated miners' clothing. In one instance a boy got the disease through cleaning his father's pit shoes, and in another case a woman was affected by washing her husband's mining clothes. Dampness in mines, and want of sanitary precautions, were among the prime causes of the disease. Disinfectants were costly and useless in preventing the spread of the disease in mines. Proper and adequate sanitary conveniences, strict systematic medical examination, and cleanly habits among the men were requisite. Such precautions had been adopted in Germany and other places with marked beneficial results.

## Correspondence.

### Circulating Reprints Without Authority.

CHICAGO, Jan. 5, 1904.

*To the Editor:*—About a year ago I began a series of observations on the therapeutic effects of a new remedy that from analogy I believed would be a valuable sedative, especially for the relief of cough. I presented the unbiased results of these observations to the Illinois State Medical Society last May and the paper was published in the *Illinois State Medical Journal* with no title following my name except M.D. Reprints were made of the article and mailed to many physicians in the state. Subsequently a reprint of this article was republished by the manufacturers of the product without my knowledge or consent, and several titles were placed after my name on the cover page. I knew nothing of this until recently when I received a copy of the reprint with a protest from some physician whose name was not given to me. The titles were only such as may be found after the names of many physicians, yet I think the protest was fully justifiable, for I believe it in exceedingly poor taste to parade one's titles even before the profession, a thing which I am not in the habit of doing. I will deem it a favor if physicians will send me any copies of this reprint they may receive hereafter.

E. FLETCHER INGALS.

## Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### POSSIBILITY OF VACCINIA AFTER SMALLPOX.

SAGINAW, Dec. 29, 1903.

*To the Editor:*—1. Is it possible for vaccine to work on a person who has recently had smallpox? 2. If so, what would you say as to probabilities following a case in the last three or four years?

P. S. WINDHAM, M.D.

ANSWER.—1. Yes, but very improbable. 2. Very improbable, but less so than after recent smallpox. It should be remembered that some other disease may be mistakenly called smallpox and that a pus lesion may be mistaken for vaccinia.

### BLOOD AGGLUTINATION.

PHOENIX, ARIZ., Dec. 26, 1903.

*To the Editor:*—Please inform me through THE JOURNAL how one can determine the agglutinating power of the human blood and its increase and decrease; also what works, if any, there are on this subject.

JOHN W. FOSS, M.D.

ANSWER.—Agglutination experiments or tests are made by mixing variable quantities of blood serum with the agglutinable objects, e. g., blood corpuscles, bacteria, and then observing the absence or development of definite clumps and masses either under the microscope or in small test tubes. The power of agglutination is generally determined roughly by finding the highest dilution at which the serum causes distinct agglutination. But there is no fixed standard of agglutinating power; it is, in all cases, normal as well as pathologic, subject to variations within wide limits. Assuming that you are especially interested in the agglutination of bacteria by human serum under various conditions, agglutinations that serve as diagnostic helps, we refer you in the first place to such works on the blood as Cabot's, Ewing's, etc., and to the annual reviews of current literature (Progressive Medicine, etc.). So far as we know there are no special books on this aspect of agglutination alone. Numerous articles have appeared in American journals on various aspects of agglutination in various diseases, especially the practical significance of its presence or absence. As an example may be mentioned L. M. Loeb on "The Serum Diagnosis of Tuberculosis," in THE JOURNAL, May 23, 1903.

## Marriages.

L. G. STEWART, M.D., to Miss May Tondee, both of Ellaville, Ga., December 23.

FRANK ANTHONY, M.D., Sterling Ill., to Mrs. Allie Sneed of Dixon, Ill., December 26.

LUCIEN STARK, M.D., to Miss Marjorie Guilfoil, both of Hyannis, Neb., December 23.

P. MAXWELL FOSHAY, M.D., to Mrs. Emily Morgan Grim, both of Cleveland, Ohio, January 6.

J. FOSTER MCNARY, M.D., to Miss Mildred Anderson, both of Milwaukee, Wis., December 24.

ALBERT W. CLARK, M.D., to Miss Harriet G. Doran, both of Punxsutawney, Pa., December 9.

R. F. HILLIARD, M.D., Urbana, Va., to Miss Stella Evans of Essex County, Va., December 29.

HARRY A. COSLER, M.D., North Hampton, Ohio, to Miss Emma Myers of Dealton, Ohio, December 29.

HENRY B. A. KUGELER, M.D., San Francisco, to Miss Louise M. Coors of Golden, Colo., December 26.

FRANK P. STAFFORD, M.D., New Carlisle, Ohio, to Miss Alberta Dresback of Sidney, Ohio, December 23.

WILLIAM C. WEST, M.D., Kansas City, Mo., to Miss Estella Bottoms of Westport, Mo., December 16.

MONTGOMERY HUNT SICARD, M.D., to Miss Adelia Avenia Ireland, both of New York City, December 22.

ALFRED LEFTWICH GRAY, M.D., Richmond, Va., to Miss Alice Lear Clark, at Charlottesville, Va., December 23.

IRA E. SEWARD, M.D., Springfield, Ohio, to Miss Laura J. Foreman of Newark, Ohio, at Columbus, December 23.

F. LOMBARD WOODWARD, M.D., Glen Echo, Md., to Miss Maude L. Burnette of Washington, D. C., December 19.

CHARLES LYBRAND BONIFIELD, M.D., Cincinnati, to Miss Grace B. Finney of Northern Ohio, at Cincinnati, December 23.

## Deaths.

**Edgar L. Carr**, M.D. Medical School of Maine, Brunswick, 1864, assistant surgeon in the Thirty-fifth Massachusetts Volunteer Infantry, died at his home in Pittsfield, N. H., December 22, as the result of injuries received in a railway accident eight days before, aged 62.

**Charles Merrill Clark**, M.D. New York University, 1857, surgeon in the Army during the Civil War, at the close of which he was chief medical officer of the district of southeastern Virginia, died at his home in Chicago, December 28, aged 69.

**William H. Bryant, M.D.** Kentucky School of Medicine, Louisville, 1853, a pioneer physician of Savannah, Mo., and for many years a member of the state examining board, died at his home, December 24, after a prolonged illness, aged 71.

**John M. Otto, M.D.** New York University, 1889, of New York City, died at the New York Hospital, December 29, from the result of injuries received in a fall the night before, in which he sustained a fracture of the skull, aged 52.

**Ambrose L. Robinson, M.D.** Cleveland Homeopathic Medical College, 1895, of Wellsville, Ohio, died at New Castle, Pa., December 25, from injuries sustained by falling from a street car in Wellsville ten days before, aged 38.

**Daniel Embury Kissam, M.D.** for forty years a physician of Brooklyn, who retired from practice in 1888, died at his home at Huntington Harbor, Long Island, December 23, aged 86. He served as surgeon in the Civil War.

**Charles S. Owen, M.D.** Chicago Homeopathic College, 1883, of Wheaton, Ill., died at the Chicago Homeopathic Hospital, January 2, from injuries sustained in the fire at the Iroquois Theater, December 30.

**Turner P. Oliver, M.D.** Medical College of the State of South Carolina, Charleston, 1851, who had practiced for more than half a century in Oglethorpe, Ga., died at Marshall, Texas, December 24, aged 84.

**Wilbur F. Harding, M.D.** Hahnemann Medical College, Philadelphia, 1857, of Westfield, Mass., died in Northampton, Mass., from fatty degeneration of the heart, December 24, after a short illness, aged 73.

**Frances Emily White, M.D.** Woman's Medical College of Pennsylvania, Philadelphia, 1872, *professor of physiology and* hygiene in that institution, died at Jamaica Plain, Mass., December 29.

**S. Foster Quimby, M.D.** Harvard University Medical School, Boston, 1864, died from cerebral hemorrhage at his home in Salem, Mass., December 23, after an illness of four days, aged 63.

**John W. Van Zandt, M.D.** College of Physicians and Surgeons of New York, 1851, died at his home in Clarkston, Wash., December 23, from paralysis, after an illness of five days, aged 73.

**Alfred J. Kurtz, M.D.** Hahnemann Medical College, Philadelphia, 1893, died at his home in Philadelphia, December 25, from injuries sustained in being run over a few days before, aged 39.

**William J. Weeks, M.D.** Harvard University Medical School, Boston, 1897, died at his home in Malden, Mass., December 23, from scarlet fever, after an illness of four days, aged 40.

**J. Fenton Underwood, M.D.** University of Vermont, Burlington, 1896, died at his home in Penn Yan, N. Y., December 20, from pneumonia, after a short illness, aged 49.

**William Kenney, M.D.,** said to be the oldest physician in Bourbon County, Ky., died at his home in Paris, December 28, after a long illness, from paralysis, aged 85.

**Joseph P. Cain, M.D.** Medical College of the State of South Carolina, Charleston, 1859, of Pinopolis, S. C., died from pneumonia, December 16, in Charleston, S. C.

**Caleb L. Sample, M.D.** Pennsylvania, 1856, a surgeon in the Confederate service, died suddenly at his home in Stillmore, Ga., December 23, from heart disease.

**Stephen H. Duley, M.D.** Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, died in Morris, Minn., December 19, from cirrhosis of the liver, aged 75.

**William B. Shuttleworth, M.D.** Jefferson Medical College, Philadelphia, 1887, of Martin's Ferry, Ohio, died at Denver, from tuberculosis, December 18.

**Richard F. Scruggs, M.D.** Jefferson Medical College, Philadelphia, 1859, died at his home in Sweetwater, Tenn., December 28, from pneumonia, aged 70.

**Robert S. Reagan, M.D.** Jefferson Medical College, Philadelphia, 1880, died at his home in Broad Ford, Pa., December 13, from typhoid fever, aged 52.

**T. Erskine Todd, M.D.** Jefferson Medical College, Philadelphia, 1876, died suddenly from heart disease at his home in Laurens, S. C., December 25, aged 49.

**Edward M. Hardcastle, M.D.** Jefferson Medical College, Philadelphia, 1844, died at his home in Easton, Md., December 27. from pneumonia, aged 84.

**Samuel Pickering, M.D.** Hospital College of Medicine, Louisville, 1879, died at his home in New Castle, Ind., December 21, from paralysis, aged 55.

**Jacob De Hart, M.D.** Medical College of Ohio, Cincinnati, 1876, died at his home in Williamsport, Ind., December 24, after a long illness, aged 58.

**Henry Koch, M.D.** University of Heidelberg, Germany, 1874, of Rochester, N. Y., died in the City Hospital in that city, December 13, aged 57.

**John Gregory Wellington, M.D.** Harvard, but never a practitioner of medicine, died at his home in Middlebury, Vt., December 18, aged 86.

**Elias H. Frantz, M.D.** Jefferson Medical College, Philadelphia, 1873, died at his home in Reading, Pa., after a prolonged illness, December 26, aged 56.

**Edwin Andrew Millring, M.D.** Niagara University, Buffalo, 1890, died from peritonitis at his home in Stockton, N. Y., December 19, aged 34.

**Hugh M. Wallis, M.D.** Jefferson Medical College, Philadelphia, 1860, died at his home in Houma, near Covington, La., December 26, aged 67.

**George F. Bradbury, M.D.** University of California, San Francisco, 1878, died at his home in Modesto, Cal., December 22, from angina pectoris.

**Daniel E. Thomas, M.D.** University of Michigan, Ann Arbor, 1858, died at his home in Constantine, Mich., December 18, from pneumonia, aged 74.

**Nathaniel P. Hackett, M.D.** Vanderbilt University, Nashville, Tenn., 1887, died at his home in Sherman, Texas, December 21, from pneumonia.

**Horatio Dallas Holmes, M.D.** of Scircleville, Ind., died at Indianapolis, December 29, from arteriosclerosis, after a long illness, aged 57.

**Robert Boocock, M.D.** New York Homeopathic Medical College and Hospital, 1891, died at his home in Brooklyn, N. Y., December 28, aged 70.

**W. J. Scott, M.D.,** of Dalby, Northampton County, Va., was found dead in his carriage near Seaview, Va., December 24, aged about 70.

**Frank Lunbeck, M.D.** College of Physicians and Surgeons of Chicago, 1884, died recently at his home in Kingston, Ohio, from heart disease.

**Augustus D. Ruggles, M.D.** University of Pennsylvania, Philadelphia, 1865, died at his home in New York City, December 27, aged 63.

**Clifford Doyle Boal, M.D.** Western Pennsylvania Medical College, Pittsburg, 1901, died at his home in Baden, Pa., December 20, aged 24.

**William L. Banfield, M.D.** University of Tennessee, Nashville, 1900, died recently at his home in Olive Hill, Rowan County, Ky.

**Horace Clifton Taylor, M.D.** Eclectic Medical Institute, Cincinnati, 1849, died at his home in Brocton, N. Y., December 21, aged 90.

**Adin P. Waid, M.D.** University of Buffalo, 1874, died at his home in Buffalo, N. Y., December 21, from cerebral hemorrhage, aged 70.

**Isaac N. Gibson, M.D.,** *the oldest physician in* Tuscarawas County, died at his home in Uhrichsville, Ohio, December 18, aged 78.

**William D. Branyon, M.D.** Barnes Medical College, St. Louis, 1899, was shot and instantly killed at Prairie Lea. December 18.

**Owen C. Brown, M.D.** University of Toronto, 1874, died at his home in Detroit, Mich., December 29, after a long illness. aged 50.

**George O. Fraser, M.D.** Cleveland Medical College, 1876, died from endocarditis, December 26, at his home in Cleveland, aged 63.

**Isaiah B. Wilson, M.D.** Medical College of Ohio, Cincinnati, 1877, died at his home in Dayton, Ohio, December 28, aged 58.

**J. C. Adams, M.D.** Medical College of Ohio, Cincinnati, 1873, died at his home in Gridley, Ill., December 28, from paralysis.

**William H. Webb, M.D.** Jefferson Medical College, Philadelphia, 1866, died at his home in Philadelphia, December 22.

**W. P. Andrews, M.D.,** Atlanta and Philadelphia, died at his home in Shelby, N. C., after a short illness, aged 80.

**W. B. Scarbrough, M.D.** Memphis, died at his home in Huntington, Texas, December 14, from pneumonia.

**William Coulson Hyde, M.D.,** died at his home in Detroit, Mich., December 28, from apoplexy, aged 74.

**W. D. Bullington, M.D.** Baltimore, 1903, died at Rincon, N. M., after a long illness, December 25, aged 26.

**Wellington E. Kneeland, M.D.**, died at his home in Lawrence, Mass., December 14, from typhoid fever.

**Gabriel M. Gunn, M.D.**, died at his home in Versailles, Mo., December 19, from pneumonia, aged 50.

**William E. Jones, M.D.**, formerly of Cumberland, Md., died at Evansville, Ind., December 26.

**Henry Bronson, M.D.** University of Vermont, Burlington, 1887, of Chicago, died recently.

**Francis W. Keyes, M.D.**, died at his home in Wilawana, Pa., December 15, aged 69.

**Minor Guinn, M.D.**, died at his home in Blacksburg, S. C., December 9.

### Deaths Abroad.

**A. Maffucci, M.D.**, professor of pathologic anatomy at Pisa, died November 25. His researches on pathologic histology and on the physiology of the serous membranes have been valuable. He also first established that the tuberculosis germ can settle in the embryo without inducing any apparent manifestations, and yet develop later in the animal.

**T. von Schroeder, M.D.**, director of the Ophthalmic Institute at St. Petersburg, and for several years editor of the *St. Petersburger Med. Woch.*, died November 18, aged 50. The above journal publishes a list of his 22 most important scientific works, most of them appearing in German periodicals as well as in the Russian.

**A. T. Almen, M.D.**, chief of the official medical service in Sweden, died at Stockholm in November, aged 71. The improvement realized in late years in hospital management throughout the country was essentially his work.

**G. Lowenbach, M.D.**, assistant at the syphilis clinic at Vienna and a frequent contributor to the medical press, was killed by an avalanche in Switzerland, in November, at the early age of 31.

**C. Philippe, M.D.**, chief of the laboratory at the Paris Faculty of Medicine, and author of several works on the histology of the nervous system, died in Paris, December 2, aged 38.

**G. De Luca, M.D.**, editor of the *Revista Clinica e Terapeutica*, privat docent of medical pathology at Naples, died November 20.

## Book Notices.

Postmortem Pathology. A Manual of Postmortem Examinations and the Interpretations to Be Drawn Therefrom. A Practical Treatise for Students and Practitioners. By Henry W. Cattell, A.M., M.D., Pathologist to the Philadelphia Hospital. With 162 Illustrations. Cloth. Pp. 372. Price, $3.00. Philadelphia and London. J. B. Lippincott Co. 1903.

This is a unique book. Its title is altogether too modest, for in its 372 pages we are also given elaborate enumerations of etiologic factors, discussion of treatment of wounds sustained in autopsies, directions for autopsies on animals, medicolegal suggestions including the Prussian regulations for the performance of autopsies in medicolegal cases, and finally a chapter entitled: "Usual causes of death; their nomenclature, complications and synonyms." The book is well and profusely illustrated and contains much useful information. The directions for postmortem technic are clear and complete. Unfortunately, this can not be said of the discussions of the pathologic findings. Classifications and tabulations are everywhere indulged in, but they are often confusing and misleading. Unessentials are frequently dwelt on at length, while essentials are barely mentioned or altogether omitted. For instance, infarcts of the kidney are classified as follows (p. 146): (a) calcareous, (b) uric acid, (c) hemoglobin, (d) bilirubin, (e) caused by salts of silver. No mention is made of the common infarcts. The only tumors of the urinary bladder named are cavernous angiomata, dermoid and echinococcic cysts. The others are dismissed with the statement that a considerable variety of tumors exists. Of the causes of acute general peritonitis exposure to cold and wet is given the first place (p. 112). The following classification of cirrhosis of the liver is given: (a) alcoholic, (b) fatty, (c) hypertrophic, (d) capsular, (e) syphilitic, (f) cyanotic, (g) malarial, (h) scarlatinal, (i) tuberculous, (j) rhachitic, (k) anthracotic. This mix-up of etiologic and anatomic factors is noticeable throughout the book. The author leaves us to guess what rôle he means "micro-organisms" to play in various diseases when he merely enumerates the word along with other factors. For instance, chronic bronchitis (p. 98): (a) certain occupations, (b) old age, (c) saprophytic and other organisms, (d) repeated attacks of acute bronchitis. The splenic form of leukemia is called splenic anemia (p. 80). The directions for securing material for bacteriologic examination at autopsies are unsatisfactory. The author does not tell us that it is possible to keep fluids in sterile pipettes and pieces of the organs in sterile test tubes or dishes until one can inoculate media at one's leisure after the autopsy. He describes under separate headings "acute cerebrospinal meningitis" due to the *Diplococcus intracellularis*, and "acute cerebrospinal leptomeningitis." Among the organisms found in the latter the "*Meningococcus*" is mentioned first. On the whole, it seems to us that the book would have been more useful if it had been confined to postmortem technic, gross pathology, and medicolegal suggestions. To scatter a syllabus of general medicine into such a work only creates confusion.

A Text-Book of Clinical Anatomy. For Students and Practitioners. By Daniel N. Eisendrath, A.B., M.D., Clinical Professor of Anatomy in the Medical Department of the University of Illinois (College of Physicians and Surgeons). Beautifully Illustrated with 153 Illustrations, a Number in Colors. Cloth. Pp. 515. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The term "Clinical Anatomy" is used to mean "anatomic knowledge as applied to every branch of clinical work," or the study of anatomy from the living subject rather than in the dissecting room. The chief feature of this work which distinguishes it from the ordinary is an attempt to outline in black on the surface of the living body the supposed location of the various organs, structures, tissues, etc., and then the photographing of the subject. As a result erroneous ideas are often conveyed. For instance, Figure 16 shows the region occupied by the parotid gland as decidedly too small, and the direction of the spinal accessory nerve as too transverse. Figure 32 shows the carotids as diverging, which is not correct, and they appear to become superficial, directly under the skin, while they are deeply situated. The division of the innominate is shown much too high, as is also the lower border of the pleura. While there are slight variations in the normal location of the kidney, Figure 42 can not be considered to represent the average normal relation of right kidney, lower edge of pleura and twelfth rib. Many of the illustrations can be looked on as simply diagrammatic and only roughly representing conditions present. There is altogether too much duplication of illustrations. For instance, Figure 21 has been introduced four times, Figure 52 three times, Figure 48 three times, while many others have been introduced twice. As the lettering and description is identical in each case there does not appear to be any good reason for so much duplication. Occasionally the text does not agree with the illustrations; for instance, on page 207 it is stated that "the lowest point of the kidney reaches down to a line drawn between the lower borders of the curves of the tenth costal cartilages." This does not agree with Figure 42. These criticisms are made with the best of motives; a book such as this should be absolutely correct and reliable; if it is not, those who expect to rely on it should be informed. The general idea and the plan of the book are most excellent, and the work will be of great value to operators who are not sure of their anatomy. The illustrations, as a rule, are excellent and reliable, and some of them, particularly those taken from actual dissections, are very good.

A Text-Book of Obstetrics. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania; Gynecologist to the Howard, the Orthopedic, and the Philadelphia Hospitals, etc. Fourth Edition, Revised and Enlarged, with 746 Illustrations, 39 of Them in Colors. Pp 899. Philadelphia, New York, London: W. B Saunders & Co. 1903.

The previous editions of Hirst's book have received adequate review; the present volume, the fourth within five years, has many additions to the text, and the illustrations have been considerably increased, which materially enhance its value. Two topics which largely have been carried from the first edition, however, are not above question. In view of the recent advances in the operative dilatation of the parturient os, and the behests of Denman and others a century ago that the os must be completely dilated before forceps may be applied, it seems unwise to recommend that forceps be applied through a partially dilated os, and to overcome the resistance of a cicatrized contraction of the cervix by traction. Likewise, the advice to perform version, then rapid extraction, through the partially dilated, rigid os, generally will mean a dead baby, and extensive, dangerous lacerations into the parametrium: it is a teaching which can not be too strongly deprecated. Under the caption of "Puerperal Sepsis" one may well be surprised to find an absence of detailed description of saprophytic or putrid infection; the mere incidental reference is not commensurate to the importance of the subject—the diagnosis, prognosis, and treatment differ so materially from the coccic infections that the omission is a grave one. We can not countenance the mandate that when in doubt all thermal disturbances in the puerperium should be considered puerperal infection and treated accordingly. Further, the growing conviction of obstetricians is against the routine curettage and repeated intrauterine douching. It seems unfair to ignore these recent teachings, and to recommend unqualifiedly these two procedures is running counter to the accumulating evidence that an expectant policy often gives best results, and sometimes active interference directly jeopardizes the patient. This expectancy is especially indicated when doubt as to the true nature of the malady is present. In spite of these criticisms, however, Hirst's text-book deserves the success it has had as a working guide for the student. The publishers' work has been done as beautifully as before.

The Worth of Words. By Dr. Ralcy Husted Bell. With an Introduction by Dr. William Colby Cooper. Third Edition, Revised and Enlarged. Cloth. Pp. 307. Price, $1.25. New York: Hinds & Noble.

This book is made entertaining by the author's pointed and humorous style and by his frequent use of pertinent anecdote. We agree with a certain reviewer of the book who regretted the title given it, because he feared that it would keep the book away from a great many persons who ought to read it, and from many more who would delight in it. But to recommend Dr. Bell as an authority is another matter. It is a delicate undertaking to sit in judgment on the constantly changing English language, of which some one has well said that it is hard to tell which is the rule and which the exception. Dr. Bell says he is not dogmatic; we fear some would so describe him. At least, he is partial and inconsistent in some particulars, for example: he condemns telegram, but admits telegraph; while he approves epigram, epigraph, monogram and monograph. He condemns photographer and gives his reason—its being made from two languages—but he says "geographer and biographer are exceptions firmly fixed in the language." We think photographer is as firmly fixed. He says bread-knife is a good word, being an abbreviation for "knife for bread," but he says cook-stove is vulgar. Is this not an abbreviation for "the stove of the cook," and is not Dr. Bell's criticism a case of the pot calling the kettle black? It is noticeable that the author himself occasionally slips into what we would call unjustifiable slang, as when he speaks of a rather innocent nickname (sky pilot) as fitting its subject "so ghastly well." Another matter for criticism is that when he is noticing his own critics his hatred of cacology, like Dowie's piety, does not prevent him from using expressions that are hardly permissible in polite usage. In spite of these, however, the book will certainly interest its readers.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-patient Medical Department of the Jefferson Medical College Hospital. Volume III. September, 1903. Diseases of the Thorax and Its Viscera, Including the Heart, Lungs and Blood Vessels; Dermatology and Syphilis; Diseases of the Nervous System; Obstetrics. Cloth. Pp. 398. Price, $2.50. Philadelphia and New York: Lea Brothers & Co. 1903.

This work, which is properly a serial, is a summary of the advance in certain lines of medical science. The subjects here discussed are diseases of the thorax and its viscera, including the heart and lungs, of which the recent literature is very adequately epitomized by Dr. William Ewart; dermatology and syphilis by William S. Gottheil; diseases of the nervous system by Dr. William G. Spiller and obstetrics by Dr. Richard C. Norris. In all four departments the book will be found well up to date and contains a well-digested summary of the principal contributions to the recent literature. We can say nothing but good of this series which Dr. Hare has so ably edited during the past few years.

Surgical Diseases of the Abdomen, with Special Reference to Diagnosis. By Richard Douglas, M.D., Formerly Professor of Gynecology and Abdominal Surgery, Medical Department Vanderbilt University. Illustrated by 20 Full-page Plates. Cloth. Pp 883. Price, $7.00. Philadelphia: P. Blakiston's Son & Co. 1903.

This work of nearly 900 pages treats of practically all the diseases and injuries of the abdomen which are likely to come under the care of the surgeon, or to require surgical treatment. As is to be expected from the title, questions relating to diagnosis are most extensively elaborated, but the other phases of the subjects have not been neglected. Treatment is the least touched on of all. Under this heading only generalities are given, and no attempt has been made to enter into the details of operative procedures or methods of treatment. This is a disappointment, for had the author extended his earnest and conscientious style so as to include this phase, it would have enhanced the value of an already excellent work. The views expressed are clearly those of a modern and aggressive man, and there is little to criticise in this regard. There is some tendency to repetition, and condensation at times would improve the text. The illustrations, only 20 in number, could be materially increased with advantage. The work, as a whole, however, is excellent, and one which should be consulted by the physician as well as the surgeon.

Nose and Throat Work for the General Practitioner. By George L. Richards, M.D., Fellow American Laryngological, Rhinological and Otological Society. Cloth. Pp. 330. Price, $2.00. Published by International Journal of Surgery Company, N. Y.

This is one of the smaller text-books which makes no pretense to being complete, but aims to meet the needs of the general practitioner. For such it will prove useful and practical.

## Miscellany.

**A Libel Exposed.**—The following item has been going the rounds of the newspapers, in a few instances commented on editorially against the profession of course:

### MUST FIRST SEE A FEE.

DOCTORS WHO WON'T SERVE UNLESS PAID IN ADVANCE.

Indianapolis, Dec. 22.—The long-heralded trust of physicians formed in Anderson has finally been demonstrated to be a fact. As a result of its operations the infant child of Mr. and Mrs. Albert Graham will die of burns received three days ago.

The Graham family is poor, and when the child was injured Mrs. Graham was forced to admit to the physicians she attempted to summon that she could not pay the fee for services until later. The agonized mother called on sixteen different doctors in vain, all refusing to attend the child until paid in advance.

The trust is said to have been formed several weeks ago. All the prominent doctors of the city are alleged to be members, binding themselves to treat no patient who owes for former professional services, and at the same time agreeing to attend no patient whose financial standing is not assured until the fee is paid in advance.

Knowing that there was little, if any, truth in the above, we wrote to Dr. O. E. McWilliams, Anderson, Ind., secretary of the Madison County Medical Society, asking him to give us the facts in the case. The following is his reply:

Anderson, Ind., Dec. 26, 1903.

*To the Editor:*—In replying to yours of the 24 inst., I have to say that I called on the Mrs. Graham to-day, and this is her statement:

That on Dec. 16, 1903, her child received a burn and she immediately called a physician by telephone; the first physician she called was not at home, the second was busy in his office and could not leave at once. She thought after calling these two she would go back home and see how bad the child was, as she was scared at first and she thought, perhaps, it was not as bad as she first thought it. When she arrived at home she saw the burn was not bad and said she would dress it herself, which she did. On the following morning, December 17, she thought she would be better satisfied if a physician should see the burn and she called a physician, who answered the call at once. Not having been informed as to the nature of the case, he had nothing with him to dress a burn, and advised the mother to call the township trustee and have him send a physician, which the mother did and the township trustee furnished a physician at once. The burn covered an area of two by six inches on the arm and the skin was not destroyed across the middle of the burn. It was a superficial burn of no consequence, nor did the mother think it of any consequence, but thought she would be better satisfied to have a physician see it. The mother said the physicians called said nothing to her about the pay for the calls, neither did she say anything about the money part of the transaction, nor does she suspect or have the least information of the notoriety she has had.

For the medical profession of Anderson, I can say that I think we have as honorable physicians as can be found any place, and I think they are all upright, honest gentlemen. I wish I could say as much of the newspapers here. They are always trying to manufacture sensational articles, and mostly out of nothing, as in this case. O. E. McWilliams.

---

**Prophylaxis of Color Blindness.**—Dr. R. Roselli has examined 100 children in respect to their color-sense. He found that it was more developed the more intelligent the children, and was most acute in girls. In a large proportion, however, it was defective; the children were unable to distinguish between various colors, but by exercises and training them to discriminate he found that all soon acquired normal color sense. He deduces the conclusion that non-acquired color blindness in the adult is due to the lack of exercise in distinguishing between colors in early life. The nerve fibrils for perception of colors become atrophied from disuse, and this in time entails an optic impotency for colors.—*Annali di Ottalmologia*, xxxii, 7-8, 1903.

**Collargol Injected Per Rectum.**—Schlesinger of Vienna proclaims that his experience has established that collargol is as effective injected by the rectum as when the intravenous route is followed. In certain cases the latter is impracticable, owing to the small size of the veins or the obesity of the patient. He found that the course of severe sepsis changed decidedly for the better in 3 cases under the influence of rectal injection of .15 to .3 gm. collargol in 75 gm. distilled water, repeated twice daily and kept up for eight days. One was a puerperal process, another thrombophlebitis after typhoid fever. In 4 other cases these injections had to be abandoned on account of pneumonia, septic diarrhea or negative results. Six febrile consumptives treated with the collargol per rectum have not shown any benefit to date.

## The Birth and Origin of Syphilis.

BY JOHN KNOTT, M.D.

DUBLIN, IRELAND.

It is a singular fact in the history of medicine that the date and the locality of the origin of syphilis have never been settled, although both have been frequently discussed ever since that disease was first definitely described in writing. A widespread story of its origin was that it was imported to Europe by the crews of Columbus from Hayti—having previously been utterly unknown on that side of the Atlantic. And that it was communicated to the French besiegers by the Spanish garrison of Naples in 1494, and thence rapidly dispersed throughout Europe. The degree of credit which the French received for its propagation is well shown by the epithet by which it was most generally known and described by physicians for the succeeding couple of centuries: that of *morbus Gallicus*. From the original locus of its European center of propagation, it was sometimes referred to as *morbus Neapolitanus;* and, on account of the ascribed Spanish-American importation, it also received the compound epithet of *scabies Hispanica*.

The racial antipathies of dirt-throwing patriots sometimes found partial vent in transferring the pathologic scandal to the nationalities whom they respectively most detested. In this way the Gallic surname of the loathsome plague was from time to time fitfully displaced in favor of that of each of the other warring nations. So that it has been called the "German disease," "Polish disease," "Turkish disease"; by the Turks the "Christians' disease," and so on. Even the name *syphilis*, by which it is now universally known, remains to the present day the *pons asinorum* of medical etymologists. Whatever may be the actual derivation of the term, its history does not appear to be traceable further back than its use by the famous Italian poet-physician, Jerome Fracastorio (1482-1553), whose metrical description of the disease, under the name *syphilis, sive morbus Gallicus*, still remains the best of the early accounts of its prominent features.

### THE ORIGINAL EUROPEAN EPIDEMIC OF SYPHILIS.

Short and very sketchy accounts of the new plague began to appear in the closing years of the fifteenth century; indeed, almost from the date of the famous siege of Naples (1494), at which it was then said to have made its first appearance. But, in connection with the story of the West Indian source of the infection, it is specially significant to note that there was no such statement made before the year 1525. But if the assertion of an American genesis of the venereal germ is conspicuous by its absence, its place is supplied with a kaleidoscopic variety of statements and theories which collectively give a very impressive idea of the infantile inventiveness and credulity which characterize the pathology of the Renaissance period.

Two of the most prominent and learned physicians of the day confidently announced their belief that the origin of the "French disease" was due to the close "conjunction" of the sun with the planets Mercury, Jupiter and Saturn, which occurred in the year 1483—which also marked the advent of one of the greatest sources of moral disturbance and destructiveness of vested interest which Europe had experienced for many centuries, in the birth of the religious iconoclast, Martin Luther! As it so happened that the year in which the great initial epidemic of venereal disease spread over Italy was also characterized by exceptionally heavy rains and inundations, the still more famous physician, Nicolaus Leonicenus, discarded the astrologic theory of Corradino Gillini and Gaspare Torella, and advanced the less elevated meteorologic one—that the outbreak of this foul disorder was really engendered by the excessive amount of moisture then existing in the heavens above and in, as well as on, the earth beneath. The great reputation of this physician governed the opinion of many subsequent authorities.

Manardi and Paracelsus both ascribed the origin of the new disease to the intercourse of a leprous man and a prostitute; the former knew of the case—the man was a Valentian by birth; the evidence possessed by Paracelsus was similar, but the male partner in his case was of French nativity. The celebrated Antonius Musa Brassavola of Ferrara informed the professional world that the original epidemic of the French evil spread from the person of a female camp-follower of the French army at the siege of Naples. But a widely different account was furnished by the famous Gabriel Fallopius of Modena—of anatomic immortality—who avers that the Spaniards, when hard-pressed by their French besiegers, poisoned the wells from which the latter obtained their supply of water, and that the new epidemic arose from that cause alone.

The celebrated Andrea Cesalpino—of physiologic immortality—tells us that he learned from persons who had been present at the siege of Naples and the other operations of that campaign that the disease really originated at the siege of Lomma, a village of the Vesuvian territory. There was a great quantity of an excellent (and much-coveted) Greek wine shut up there. One night the besieged Spanish garrison managed to effect their escape, leaving behind them the greater part of their wine—which they had previously mingled with the blood of the sick of San Lazaro. The French besiegers, on entering the place next day, with the usual pillaging instincts of "that dissipated nation," drank freely of the luscious wine —after which they soon began to develop venereal symptoms. The noted Bolognese physician, Leonardo Fioravanti, states that he was informed by the son of a person who had been sutler to the army of Alfonso, King of Naples, that when the meat supply began to run short on account of the prolonga*tion of the war this sutler* supplied the camps with dressed human flesh instead. The unconscious cannibalism which followed the grewsome fraud was the immediate cause of the development of the *morbus Gallicus*. Indeed, the famous English philosopher, Lord Chancellor Bacon, quotes this story, as he does so many other "old wives' tales," with patronizing credulity; and informs us, too, that the human flesh supplied on that epoch-making occasion was of men killed in Barbary, and which had been prepared and dressed after the manner employed with that of tunny-fish.

While so much mythologic lore remains connected with the origin of the great epidemic of syphilis which swept Europe at that date, it is no matter for surprise that the question of the existence of the disease in ancient times still remains a matter of dispute.

## State Boards of Registration.

### COMING EXAMINATIONS.

Indiana State Board of Medical Registration and Examination, Indianapolis, Jan. 13, 1904. Secretary, Dr. W. T. Gott, Crawfordsville.

Board of Medical Examiners of South Dakota, Cataract Hotel, Sioux Falls, Jan. 13-15, 1904. Secretary, Dr. H. E. McNutt, Aberdeen.

Wisconsin Board of Medical Examiners, Milwaukee, Jan. 12, 1904. Secretary, Dr. F. R. Forsbeck, Milwaukee.

State Medical Board of Arkansas, Little Rock, Jan. 12, 1904. Secretary, J. P. Runyan, Little Rock.

Vermont State Board of Medical Censors, Y. M. C. A. Bldg., Burlington, Jan. 13-14, 1904. Secretary, Dr. S. W. Hammond, Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, Jan. 14, 1904. Secretary, Dr. Wm. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, Jan. 14-16, 1904. Secretary, Dr. J. A. Egan, Springfield.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

New York State Board of Regents, at New York, Albany, Syracuse and Buffalo, Jan. 26-29. Secretary, James Russell Parsons, State Capitol, Albany.

Texas Report.—Dr. M. M. Smith, Austin, secretary of the Board of Medical Examiners for the State of Texas, reports the written examination held at Ft. Worth, Oct. 13 to 15, 1903, as follows: Subjects, 13; questions, 125; percentage required, 75; candidates, 34; passed, 24; failed, 10. Undergraduates numbered 8 of those who passed, or one-third, and 5 of those who failed, or one-half. The graduates are listed below:

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Chattanooga Medical College | 1903 | 75 |
| Medical Department Tulane University | 1902 | 86 |
| Medical Department Tulane University | 1902 | 84 |
| Jefferson Medical College | 1875 | 75 |
| Med. Dept., University of Tennessee | 1898 | 86 |
| Illinois Medical College | 1902 | 81 |
| Indiana Medical College | 1903 | 77 |
| Med. Dept., University of Texas | 1903 | 83 |
| Hospital College of Medicine (Louisville) | 1903 | 87 |
| Medical Department, University of Kentucky | 1903 | 79 |
| Dallas Medical College | 1903 | 77 |
| College | 1903 | 84 |
|  | 1903 | 88 |
| " | 1898 | 75 |
| " | 1894 | 75 |
| " ine (Louisville) | 1885 | 83 |

FAILED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| University of Louisville (Kentucky) | 1878 | 70 |
| Chattanooga Medical College | 1901 | 69 |
| Medical College of Ohio | 1901 | 72 |
| Illinois Medical College | 1903 | 71 |
| Tennessee Medical College | 1899 | 71 |

The questions asked were as follows:

#### GYNECOLOGY.

1. Give the blood and nerve supply of the uterus, ovaries and vagina. 2. What are the means used in examination of the pelvic organs of the female? 3. Describe the preparation necessary for an aseptic gynecologic operation in private practice. 4. Give the etiology, pathology, diagnosis and treatment of vulvitis pruriginosa, or pruritis of the vulva. 5. Give the pathology, symptoms, prognosis, complications and treatment of specific vaginitis. 6. (*a*) Give the subjective and objective symptoms of imperforate hymen. (*b*) Describe the operation for its relief. (*c*) The dangers attending or following operation and after-treatment. 7. (*a*) Give the ascribed causes of calculus in the female bladder. (*b*) The most common varieties. (c) The different methods of treatment of the same. 8. What are uterine fungosities; symptoms and technic of treatment? 9. What are the most common benign growths found in the cavity of the uterus; causes, symptoms and treatment? 10. (*a*) Give the causes of retroversion and retroflexion of the uterus. (*b*) Give the differential diagnosis between the two. (*c*) The treatment of each.

#### CHEMISTRY.

1. How would you test for albumin in the urine by heat. State possible errors. 2. What is Heller's test for albumin in urine? 3. What is Trommer's test for sugar in urine, and how made? 4. Give Marsh's test for arsenic. 5. Describe an electric battery, and explain the operations of the chemicals used. 6. Give the chemistry of respiration, showing what is inhaled, what is exhaled and how the gases enter and leave the blood. 7. How is oxygen administered to a patient in bed? 8. What are the chemical antidotes to be used in carbolic acid poisoning? 9. What chemical antidotes should be used in corrosive sublimate poisoning? 10. What chemical antidote should be used in arsenical poisoning, and how would you prepare it?

1. Define blood pressure and the different agencies by which it is maintained. 2. Name the two chief divisions of the nervous system, and explain the difference in function between an afferent and an efferent nerve. 3. Explain the function of bile and the glycogenic function of the liver. 4. Explain the mechanism of respiration and the changes which take place in the blood and the air breathed during the same. 5. Name the important constituents of gastric juice and the final product of gastric digestion. 6. What route does fat take to reach the blood stream? 7. What is the ordinary temperature of the body in health, and how is it maintained? 8. Give the origin and function of the different fibers of the trifacial nerve. 9. Name the respiratory center and give the function of the tenth cranial nerve. 10. Describe the temporary and permanent teeth and the usual age for the eruption of each.

#### PATHOLOGY.

1. What diseases are attended with ulceration of the intestine? 2. What diseases are attended with cardiac hypertrophy? 3. What general pathological lesion characterizes chronic alcoholism? 4. What degenerative changes occur in the walls of an artery? 5. Give pathology of malarial cochexia. 6. Give pathology of scarlet fever. 7. What diseases are characterized by the formation of a membrane in the throat? 8. Give pathology of locomotor ataxia. 9. What changes are produced in the cerebral tissues by a thrombus? 10. Give pathology of acute pleurisy.

#### HISTOLOGY.

1. Name different varieties of epithelium. 2. Describe the periosteum. 3. Where is non-striped muscular tissue found? 4. Name and describe the coats of an artery. 5. Describe the wall of a capillary blood vessel. 6. Describe a lymph gland. 7. Give the structure of the pia mater of the brain. 8. Give the structure of a hepatic lobule. 9. Describe an air cell. 10. Give structure of a malpighian corpuscle.

#### MEDICAL JURISPRUDENCE.

1. Of what does medical jurisprudence treat? 2. What do you understand by the term "medical expert"? 3. State the difference between criminal and civil malpractice. 4. Give in detail the duties of the practitioner who is called to inspect a dead body. 5. What precautions are absolutely necessary to make a physician's testimony of value, when vomited matters, medicines, articles of clothing, blood stains, or any part of the human body is committed to his care for inspection or analysis? 6. Name some of the violent causes of death. 7. Give in detail the conditions which would warrant the induction of abortion by the practitioner. 8. At what stage of intrauterine life does the fetus become viable? 9. What are the evidences of a live birth subsequent to respiration? 10. Define the word "insanity."

#### PRACTICE OF MEDICINE.

1. Mention briefly the diagnosis and treatment of yellow fever, and the measures to prevent its spread. 2. Give the symptoms and treatment of diphtheria. 3. Give the varieties of malarial fever and their treatment. 4. Give the treatment of typhoid fever, and state briefly the measures to prevent infection. 5. Give in detail the early diagnosis of tuberculosis of the lungs, and briefly the treatment. 6. State briefly the care and treatment of scarlet fever until dismissed. 7. Give the diagnosis and treatment of lobar pneumonia. 8. Give the diagnosis and treatment of Bright's disease. 9. Give briefly the management and treatment of smallpox. 10. Give the medical treatment of appendicitis.

#### OBSTETRICS.

1. (*a*) Give the anatomy of the ovaries, (*b*) the uterus, (*c*) the vagina, and (*d*) the anatomic relations of each. 2. Describe the phenomena of ovulation and menstruation. 3. Describe the development of the fetus in the different months of pregnancy. 4. Give the causes and prevention of abortion, and treatment of inevitable abortion. 5. State some of the more important physiologic changes in the genitalia during a normal pregnancy. 6. State some of the more important changes in the maternal organism during pregnancy. 7. (*a*) Is the pregnant woman immune from any disease? (*b*) Does pregnancy modify or increase the severity of acute infectious diseases? (*c*) What are the chief dangers? (*d*) State in full what is the duty of the physician in regard to pregnant women during epidemics. 8. Puerperal infection: Give its etiology, pathology, diagnosis, prevention and treatment. 9. (*a*) What is the difference between the insanity in the pregnant woman and the puerperal state and that at any other period of the woman's existence? (*b*) What are the predisposing causes of insanity in the pregnant and puerperal state? 10. What are the symptoms of the so-called puerperal insanity? Give an outline of its treatment.

#### MATERIA MEDICA AND THERAPEUTICS.

1. What is (*a*) Fowler's solution, (*b*) Donovan's solution, (*c*) brown mixture, (*d*) Monsell's solution? 2. Name the principal local systemic emetics, and give their doses. 3. Physiologic action and therapeutics of pilocarpin. 4. What is (*a*) *Mentha peperita* and (*b*) *Mentha virides*, with their preparations and doses. 5. What are (*a*) escharotics, (*b*) antipyretics, (*c*) anthelmintics and (*d*) emollients? Name principal drugs belonging to each group. 6. What is (*a*) an alkaloid, (*b*) a decoction, (*c*) a tincture, and (*d*) a fluid extract? 7. What is the physiologic action of amyl nitrite, and for what is it used? 8. For what is arsenic used? Give symptoms and treatment of a case of arsenic poisoning. 9. Name the various groups of cathartics. Give the names of members of each group with their different actions. 10. What is the source of digitalis? Name its preparations and their doses.

### SURGERY.

1. Give the rules to be observed in administering a general anesthetic. 2. In case of threatened death from general anesthesia, what measures should be instituted? 3. Describe an amputation of the middle third of the thigh, and the antiseptic precautions before operation. 4. Under what circumstances should you operate in a case of gangrene? 5. Under what circumstances should you operate in a case of appendicitis? 6. Give the different varieties of stricture of urethra and methods of treatment. 7. Classify the different dislocations of hip joint, and treatment of each. 8. Give different methods of arresting arterial hemorrhage. 9. Give different methods of treating hemorrhoids. 10. Give diagnosis and treatment of fistula in ano.

### EYE, EAR AND THROAT.

1. Give diagnosis and treatment of iritis. 2. Give diagnosis and treatment of acute glaucoma. 3. Give diagnosis and prognosis in recurrent fibroma of nose. 4. Give etiology and treatment of mycosis of external ear. 5. Give diagnosis and treatment of mastoid disease or suppurative otitis media.

### HYGIENE.

1. At what temperature would you keep a sick room, and how ventilate it for a patient with pneumonia? 2. Give details of fumigating a room, recently occupied by a patient with scarlet fever, with sulphur and with formalin. 3. In hospitals, prisons, etc., what should be the minimum number of cubic feet of air space allowed for each occupant? 4. How soon should a child be allowed to return to school after having had scarlet fever? 5. What is the best general method of purifying drinking water? 6. Where is the contagion of typhoid fever found; how carried, and how is the spreading of the disease prevented? 7. At what temperature is it necessary to heat milk to sterilize and pasteurize it? 8. Below what degree of temperature is it necessary to keep milk to prevent its souring or "turning"? 9. What per cent. of the oxygen inhaled is consumed during an ordinary inspiration? 10. What per cent. of carbonic acid gas is there in exhaled air during ordinary respiration?

### ANATOMY.

1. Describe the upper third of the femur. 2. Describe the ankle joint, giving also the articulation of bones entering into its formation. 3. What anatomic structures would be cut in an amputation of the upper third of the leg? 4. Describe the fourth ventricle. 5. Give the origin, course and distribution of the inferior maxillary nerve. 6. What is Scarpa's triangle? Give its boundaries and relation of the vessels and nerve. 7. Give the origin, insertion, nerve supply and action of the following muscles: Pronator radii teres, biceps, and levator ani; describe each separately. 8. Give the origin, course and branches of the external carotid artery. 9. Describe the kidney, giving its relation and also the relation of the structures entering and leaving it. 10. Give a brief anatomy of the entire alimentary tract.

---

# The Public Service.

## Army Changes.

Memorandum of changes of stations and duties of medical officers, for the week ending Jan. 2, 1904:

Williams, A. W., asst.-surgeon, leave of absence extended for twenty-three days.

Truby, W. F., asst.-surgeon, granted leave of absence for one month.

McMillan, Clemens W., contract surgeon, relieved from further duty in the Division of the Philippines, and at the expiration of his two months' leave of absence, to proceed to Fort Myer, Va., for duty.

Stone, Frank P., contract dental surgeon, relieved from further duty in the Division of the Philippines, and at the expiration of his month's sick leave of absence, will report for duty at the Presidio of San Francisco.

Hammond, William G., contract dental surgeon, when relieved from duty at the Presidio of San Francisco, will proceed to Manila for duty in the Division of the Philippines.

Watkins, Victor E., contract surgeon, now at San Francisco, is ordered to duty in the Department of California, and will not go to the Philippines.

Gibson, Edward T., contract surgeon, recently arrived at Fort Ethan Allen, Vt., with the 15th Cavalry from the Philippine Islands, has been granted leave of absence for one month.

Kemp, James F., contract surgeon, recently returned to Washington, D. C., from Philippine service, has been granted leave of absence for one month.

Fisher, William C., contract dental surgeon, is now in Washington, D. C., on leave of absence from Fort Wayne, Mich.

## Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Jan. 2, 1904:

Marcour, R. O., asst.-surgeon, detached from the *Franklin* and ordered to the *Dixie,* for duty with the Panama Marine Brigade.

Brister, J. M., asst.-surgeon, detached from the *Isla de Cuba* and ordered home.

Guthrie, P. A. surgeon, ordered to the *Franklin.*

Freeman, G. F., P. A. surgeon, ordered to the naval station, Olongapo, P. I.

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Jan. 2, 1904:

### SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, Dec. 12-19, 1 case.

California: San Francisco, Dec. 13-20, 3 cases.

Colorado: Denver, Nov. 14-28, 3 cases.

Illinois: Chicago, Dec. 19-26, 4 cases.

Indiana: Evansville, Dec. 19-26, 1 case.

Louisiana: New Orleans, Dec. 19-26, 1 case.

Maine: Dec. 19, Brewer, 1 case; Old Town, 9 cases; Orono, 1 case.

Massachusetts: Dec. 19-26, Brockton, 1 case; Fall River, 1 case; Haverhill, 1 case.

Michigan: Dec. 19-26, Flint, 1 case; Port Huron, 2 cases.

Nebraska: Omaha, Dec. 19-26, 1 case.

New Hampshire: Manchester, Dec. 19-26, 2 cases.

New York: New York, Dec. 19-26, 1 case.

Ohio: Cincinnati, Dec. 18-25, 8 cases; Dayton, Dec. 19-26, 4 cases; Youngstown, Dec. 12-19, 12 cases.

Pennsylvania: Altoona, Dec. 12-19, 1 death; Dec. 19-26, Erie, 1 case; Philadelphia, 66 cases, 14 deaths; Pittsburg, Dec. 16-23, 18 cases, 6 deaths.

South Carolina: Charleston, Dec. 19-26, 1 case, imported.

Tennessee: Memphis, Dec. 19-26, 17 cases.

Wisconsin: Milwaukee, Dec. 19-26, 10 cases.

### SMALLPOX—FOREIGN.

Austria-Hungary: Nov. 28-Dec. 5, Prague, 20 cases; Trieste, 1 case.

China: Shanghai, Nov. 14-21, 1 death.

Colombia: Barranquilla, Dec. 5-13, 3 deaths.

France: Paris, Dec. 4-12, 17 cases.

Great Britain: Dec. 5-12, Birmingham, 2 cases, 1 death; London, 2 cases; Manchester, 2 cases; Newcastle-on-Tyne, 1 case; Nottingham, 1 case; Glasgow, Dec. 11-18, 28 cases, 1 death.

India: Bombay, Nov. 24-Dec. 1, 1 death.

Netherlands: Rotterdam, Dec. 5-12, 1 case.

Russia: Moscow, Nov. 21-Dec. 5, 5 cases, 3 deaths; Odessa, Nov. 28-Dec. 5, 6 cases; St. Petersburg, Nov. 16-Dec. 5, 81 cases, 2 deaths.

Turkey: Beirut, Nov. 28-Dec. 5, present; Smyrna, Nov. 22-29, 7 deaths.

Uruguay: Montevideo, Sept. 5-Oct. 31, 12 cases.

### YELLOW FEVER—UNITED STATES.

Texas: Laredo, Dec. 26, 1 case.

### YELLOW FEVER—FOREIGN.

Colombia: Cartagena, Nov. 23-30, 1 death.

Mexico: Dec. 6-12, Ciudad Victoria, 3 cases, 2 deaths; Merida, 2 cases, 1 death; Vera Cruz, 9 cases, 2 deaths.

### PLAGUE—INSULAR.

Philippine Islands: Manila, Oct. 24-Nov. 14, 2 cases, 2 deaths.

### PLAGUE—FOREIGN.

Australia: Brisbane, Sept. 1-30, 1 case, 1 death.

China: Hongkong, Nov. 7-14, 1 death.

Egypt: Nov. 21-28, Alexandria, 1 case, 1 death; Minieh, 3 cases, 1 death.

India: Bombay, Nov. 24-Dec. 1, 51 deaths; Calcutta, Nov. 14-28 43 deaths; Karachi, Nov. 22-29, 8 cases, 7 deaths.

Mauritius: Nov. 12-Dec. 3, 208 cases, 114 deaths.

### CHOLERA—INSULAR.

Philippine Islands: Manila, Oct. 24-Nov. 4, 19 cases, 18 deaths; Provinces, Oct. 24-Nov. 14, 551 cases, 418 deaths.

### CHOLERA—FOREIGN.

India: Madras, Nov. 14-20, 3 deaths.

Japan: Nagasaki, Nov. 21-30, 1 death.

Straits Settlements: Singapore, Nov. 7-14, 5 deaths.

---

# Medical Organization.

## Iowa.

Lyons County Medical Society.—The physicians of the county met at Rock Rapids, December 29, and organized a society on the standard plan, with 19 charter members, and the following officers: President, Dr. Z. T. Holtsclaw, Larchwood; vice-president, Dr. W. W. Bartine, Rock Rapids; secretary and treasurer, Dr. W. T. Schwabland, Lester, and censors, Drs. John E. North, Rock Rapids, John F. Brott, Doon, and Alexander Macnab, Rock Rapids.

## Maryland.

Carroll County Medical Society.—This society was organized at Westminster, December 8, with the following officers: President, Dr. J. Howell Billingslea, Westminster; secretary-treasurer, Dr. Charles R. Foutz, Westminster, and vice-presidents (one from each district) Dr. Clotworthy Birnie, Taneytown; Luther Kemp, Uniontown; John J. Stewart, Silas M. Gorsuch, Finksburg; Daniel B. Sprecher, Sykesville; James H. Preston, Manchester; Joseph T. Hering, Westminster; Richard C. Wells, Hampstead; Edwin D. Cronk, Westminster, Charles H. Diller, Double-pipe Creek; G. H. Winterson, W. Durbin Brown, Union Bridge, and William E. Gaver, Mountairey. Drs. J. McPherson Scott, Hagerstown, and G. Milton Linthicum, Baltimore, representing the Medical and Chirurgical Faculty of Maryland, were present, and made addresses on the needs, purposes and benefits of medical organization.

### New Jersey.

**Camden County Medical Society.**—At a meeting held in Camden, December 8, the District Medical Society reorganized under the standard plan, as the Camden County Medical Society.

### North Carolina.

**Sixth District.**—Dr. Hubert A. Royster, Raleigh, councilor for this district, announces under date of December 26 that he has effected organization in all counties in his district with the exception of Warren County, where his efforts have as yet been unsuccessful.

**Vance County Medical Society.**—This society has been organized by Dr. Hubert A. Royster, Raleigh, councilor for the Sixth District, with the following officers: President, Dr. Robert J. Gill, Henderson; vice-president, Dr. Fletcher R. Harris, Henderson; secretary and treasurer, Dr. George A. Coggeshall, Henderson, and censors, Drs. John H. Tucker, Henderson, C. G. Ferabee, Kittrell, and William McAllister, Middleburg.

**Franklin County Medical Society.**—Dr. Hubert A. Royster, Raleigh, councilor for the Sixth District, announces the organization of this society with the following officers: Dr. James E. Malone, Louisburg, president; Dr. J. J. Mann, Stallings, vice-president; Dr. Samuel P. Burt, Louisburg, secretary and treasurer, and Drs. Ivy G. Riddick, Youngsville, Richard B. Henderson, Franklinton, and John R. Wheless, Centerville, censors.

### Ohio.

**Ninth District Medical Society.**—This district society, the first to be organized in the state, met at Jackson, December 3, and with the aid of Dr. John E. Sylvester, Wellston, councilor for the district, perfected its organization and elected the following officers: Dr. Orrin C. Andre, Waverly, president; Dr. Joseph S. Rardin, Portsmouth, vice-president, and Dr. Lester Keller, Ironton, secretary and treasurer. About 60 physicians were present, including Dr. Brooks F. Beebe, chairman of the council, and Drs. Charles L. Bonifield and Horace J. Whitacre, Cincinnati.

### South Dakota.

**Sixth District Medical Society.**—The secretary notifies us that the report of the election of officers of this society, which appeared in The Journal, December 26, should be amended so as to read that Dr. Rodell E. Warne, Mitchell, was elected delegate to the state society, and Dr. Roscoe H. Goodrich, Chamberlain, alternate.

### Texas.

**El Paso County Medical Society.**—This society was reorganized at El Paso, December 12, in compliance with the rules and regulations of the American Medical Association, with the following officers: President, Dr. Junius A. Rawlings; vice-president, Dr. M. P. Schuster; secretary, Dr. Gottlieb Wehrle; treasurer, Dr. Edward H. Irvin; delegate to Texas State Medical Association, Dr. Stephen T. Turner, and censors, Drs. William H. Anderson, Marcus O. Wright and Herbert E. Stevenson, all of El Paso.

### Wisconsin.

**Dane County Medical Society.**—This society, which was formed September 17, perfected its organization by adopting the standard constitution and by-laws at its meeting in Madison, December 15, at which the following officers were elected: President, Dr. Cornelius A. Harper, Madison; vice-president, Dr. William F. Pinkerton, Mazomanie; secretary and treasurer, Dr. Reginald H. Jackson, Madison, and Dr. Niels C. Evans, Mount Horeb, delegate to state society.

---

# Society Proceedings.

## SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Sixteenth Annual Session, held in Atlanta, Ga., Dec. 15-17, 1903,*

*(Continued from page 53.)*

### Neoplasms, Wherever Situated, Should, if Possible, Be Removed, Whatever Their Apparent Nature.

**Dr. Maurice H. Richardson**, Boston, gave reasons for the rule, stated in the title, pertaining chiefly to neoplasms of the breast and of the female pelvis, but applying with certain exceptions to all parts of the body. These reasons, all of which were illustrated by specific cases of his own, were as follows:

1. The uncertainty of the diagnosis, even by those most experienced and skilful, makes palliative treatment hazardous, especially in doubtful cases. Cases were referred to; as of breast tumors apparently benign which had proved malignant, or in which minute foci of malignancy were discovered, or which after many years developed a fatal malignancy, etc.
2. Benign tumors may become malignant.
3. The wisdom of exploration in certain apparently hopeless tumors is illustrated by cases in which a benign and easily remediable condition was found, and in which impending death was averted by a safe operation. Thus supposedly malignant tumors proved to be curable tuberculosis foci; epigastric tumors, apparently cancerous, to be pancreatic cysts, etc.
4. Certain organs have a malignancy-inviting nature, especially the breasts and the ovaries.
5. The benign often masks the malignant, especially in pelvic tumors. For example, the obscuration of a uterine sarcoma by an overlying fibroid.

The rule of universal extirpation has numerous exceptions. It should not apply to superficial tumors, clearly benign, which can not be removed without great disfigurement unless they show a tendency to ulceration and malignancy; or to other benign tumors, the removal of which would cause needless suffering, disability, disfigurement, or danger; or to tumors of all kinds in which the dangers and sufferings of removal outweigh the dangers and sufferings of the tumors themselves.

#### DISCUSSION.

**Dr. Henry T. Byford**, Chicago, said he belonged to the Chicago Academy of Medicine, whose motto is: "When you see a head, hit it." He thought this would fittingly apply to the removal of tumors as soon as they were seen. He cited a tumor the size of a hickory nut, situated between the bladder and uterus, which the attending physician said did not amount to much, arguing against operation. The woman subsequently became pregnant, miscarried at the fifth month, the tumor having attained the size of an egg. No matter whether a tumor is going to become malignant or not, it is a foreign body and should be removed as soon as possible.

**Drs. W. P. Nicolson**, Atlanta, and **W. B. Coley**, New York, narrated cases, the latter speaking of an eminent surgeon, who watched a tumor for a year, telling the patient not to have anything done until he thought she needed it. When the tumor was finally pronounced cancer and removed, recurrence soon caused death. Dr. Coley thought these growths should be removed without waiting to determine whether they were malignant or not.

**Dr. W. P. Carr** thought that a routine practice of examining microscopically all small benign tumors removed would show many of them to be malignant.

**Dr. J. M. Baldy**, Philadelphia, supported the essayist in saying that these neoplasms ought to be removed, no matter where they occurred. In the past year he had reoperated twice on cases of cancer that had been subjected to *x*-ray treatment, and in one he had operated a third time for the return of the disease after *x*-ray treatment, although the physician who had used the *x*-ray had said the patients were doing satisfactorily.

**Dr. J. Shelton Horsley** mentioned a case of cancer of the breast in which there was local recurrence after operation, and the patient was treated by the *x*-ray without benefit.

### Intestinal Cancer.

**Dr. J. G. Sherrill**, Louisville, Ky., in a paper on this subject, stated that cancer of the intestine, while rare, was more frequent than physicians were led to believe; that sarcoma was much less frequent than carcinoma, and selected especially the small intestine, while carcinoma most often attacked the large bowel. The appendix is the seat of both carcinoma and sarcoma, although occurring infrequently. The literature shows that men suffer from both forms oftener than do women. Adenocarcinoma is the type most frequently seen, while the round-celled sarcoma or the lymphosarcoma occurs oftenest. The author reported two cases. He said that the treatment was to be largely determined by the extent of the involvement. Resection of the intestine and extirpation of the growth offer the only hope of a permanent cure, and this chance should be taken as early as possible.

### Amputation of the Hip-Joint for Sarcoma, with a Report of Seven Cases Without Mortality.

Dr. Wm. B. Coley, New York, in a paper on this subject, said that the tumor originated in the bone or periosteum of the femur in 5 cases, and in the soft parts in 2. The age of the patients ranged between 6 and 56 years. In 6 cases Wyeth's pins were used, but the growth extended above Poupart's ligament and pins could not be used, so the external iliac artery was first tied. All of the patients made a good recovery from the operation, but only one patient survived operation long enough to be called a cure. This was a sarcoma of the thigh in which the mixed toxins of erysipelas and *Bacillus prodigiosus* were used for two months before amputation. In one recent case the patient was still alive without recurrence; in all the other cases death occurred from local or general recurrence in from four months to two years after amputation. Of 4 other cases of sarcoma of the femur and thigh, treated by high amputation, just below the trochanter, 2 patients died at the end of four months; 1 died at the end of two and a quarter years, and 1 had recurrence in the gluteal region, which disappeared under the mixed toxin treatment, and the patient is alive at present without recurrence, six years afterward.

The extraordinary malignancy of sarcoma of the femur was shown by the very small number of patients known to have survived for more than three years after amputation. He advised systematic use of the erysipelas toxin after primary amputation as a prophylactic against recurrence. He would not advise such treatment prior to amputation in sarcoma of the femur. on account of the great liability to early metastases.

The method advocated by Mikulicz, resection of the femur, Coley did not think should be adopted as a substitute for amputation, as there were no cases treated by this method that had been observed for longer than a year, hence nothing could be said as to permanent cure.

The *x*-ray, he believed, should never be used unless the patient absolutely refused amputation.

### Surgery of Urinary Tuberculosis in Women.

Dr. Guy L. Hunner, Baltimore, reported 35 cases occurring in the services of Dr. Howard A. Kelly and his associates in Baltimore. These patients were all women with an average age at the onset of symptoms of 28 years. The disease was unilateral in 31 of the cases, and it was probably primary in the kidney, as regards the urinary system, in 30 or more of the cases; 31 cases had bladder symptoms at some time in the course of the disease, although only 18 cases had bladder lesions at the time of operation; 11 of these 18 cases still had some bladder symptoms, and 5 were known to have bladder lesions, although 9 of the 11 had had systematic bladder treatment. Tuberculosis of the bladder does not heal with the ordinary methods of treatment, and if the disease persists a year and does not occupy more than half of the bladder, it should be excised. Of 22 ureters examined microscopically, 17 showed tuberculosis, while 5 were chronically inflamed. If a tuberculous ureter remained either in part or *in toto*, the wound usually remained open at least two years, while the removal of the ureter with the kidney resulted in rapid closure of the wounds. Five cases died, three after six and eleven weeks, and two years, respectively, from involvement of the other kidney, and two, in fifteen and six days, because of the operation. Sixty-six per cent. of the patients were enjoying fairly good or excellent health.

### Spurious Dysmenorrhea.

Dr. Henry T. Byford, Chicago, read a paper with this title in which he made a plea for more rational treatment. The absurdity of the nasal cure was emphasized and the cures referred to as spurious. The trend of the paper was to condemn writers for bringing the symptom into the foreground when it should be kept in the background, and for wasting their own time and that of their readers in ridiculous speculations.

### Memorial Address on Dr. W. E. B. Davis.

Dr. Richard Douglas, Nashville, Tenn., spoke eloquently of the work that had been accomplished by Dr. Davis, and pointed out in a masterly manner the distinguishing characteristics of the deceased.

### Diagnosis and Treatment of Congenital Misplacement of the Hip in Infancy.

Dr. Albert H. Freiberg, Cincinnati, had been able to ascertain that in several cases children with congenital misplacement of the hip had been late in walking, though they were able to stand at the usual age for walking. In some few instances mothers observed these things and possibly also that the apparent breadth of pelvis and perineum was unusually great. It was, therefore, urged that in the presence of any of these signs which had been referred to attention be paid to the possibility of congenital luxation, and that in the event of any doubt the *x*-ray be resorted to as a final means of precision. Experience has abundantly shown the feasibility of operative procedure after the age of one year, and that the results amply justify the great additional care which was necessary to prevent the dressings from becoming soiled in so young a patient.

### The Progress of Ureteral Surgery.

Dr. J. Wesley Bovée, Washington, D. C., president of the association, after referring to the deaths of Drs. W. E. B. Davis, George J. Engelmann, and J. McFadden Gaston, spoke on the surgery of the ureter, giving its history and present status. The *x*-ray is the simplest procedure for diagnosis of calculi, but it is not at all times reliable. For this reason especially other plans of examination should be employed.

In the treatment of ureteral calculi he advocated extraperitoneal ureterolithotomy, as infected urine was usually associated with this condition and easily produced peritonitis. If pus was not present, the establishment of ureterocutaneous fistula would seldom be necessary, though careful drainage of the wound would be advisable. The ureteral wound should be made longitudinally whenever possible, and sutured after lithotomy. If there was much necrosis of the ureter resection or exsection, with uretero-ureteral anastomosis or ureterocystostomy might be required. Frequently pyonephrosis accompanied calculous ureteritis. Incision and drainage, and probably nephrolithotomy would be needed in addition. For ureteral fistula nothing need be done unless obstruction of the duct below the fistulous opening existed. In such a case the caliber of the canal must be restored. In subcutaneous injury of the ureter, no treatment is advisable unless evidence of extravasation of urine or of ureteral obstruction exists. Abnormal ureteral terminations of congenital origin might be corrected by ureterocystostomy, usually by the vaginal route. In complete ureterectomy or nephro-ureterectomy in women probably the loin and vaginal incisions constitute the best plan.

## THE WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Thirteenth Annual Meeting, held at Denver, Dec. 28 and 29, 1903.*

The Association met at the Brown Palace Hotel, under the Presidency of Dr. Alexander Hugh Ferguson of Chicago.

### Carcinoma of the Lung and Pancreatic Cyst.

Dr. W. W. Grant, Denver, reported two cases of carcinoma of the lung, and one of pancreatic cyst. He reviewed the literature, which shows convincingly that the disease is essentially surgical, and that delay in operating is as dangerous and fatal as in appendicitis. The suggestion in the treatment of the sac was to dissect it out if small, but in the case of a large sac this attempt is manifestly unsafe and dangerous. The extensive adhesions make it exceedingly difficult, and extravasation of pancreatic juice or septic material will probably destroy the patient. Patients have died from this treatment; while to attach the sac to the abdominal peritoneum, if not already adherent, and drain, is safe and undoubtedly the best treatment of a large cyst. Pancreatic juice out of its normal channel produces fat necrosis. Pancreatic disease often simulates intestinal obstruction, and the statement may be safely accepted that if the surgeon opens the abdomen and does not find obstruction or perforation of the stomach, but observes fat necrosis, the pancreas is, in all probability, the source of the trouble.

### DISCUSSION.

Dr. M. L. Harris, Chicago, spoke of the great value of colonic and systematic distention of the intestines. In going over the literature of pancreatic cyst he found that in 95 per cent. of the cases the transverse colon took a distinct circle below the tumor and the stomach above. There is practically no other tumor or cyst in which this relation is found.

Dr. Grant said several writers had considered the differential diagnostic point mentioned by Dr. Harris, but when it was remembered that cases of pancreatic cyst were more frequent in very fat subjects, and that there was very uniform distention of the intestines, the stomach not being so much distended because of the pressure of the tumor, or, if so, it was entirely out of its normal location, it was difficult, if not impossible, to isolate the transverse colon and the stomach. He had never succeeded in getting any benefit from artificial distention in other cases, although he did not try it in this case.

## Accidental Perforations of the Uterus.

Dr. D. S. Fairchild, Des Moines, Iowa, said that the use of the sound and the curette in gynecologic practice was probably the most frequent cause of this accident in legitimate practice. The facility with which the sound can be used in exploring the interior of the uterus and in replacing a retrodisplaced organ is no doubt responsible for some of these accidents. The curette, however, is often used in an indiscriminate manner and as a routine treatment in a great variety of uterine difficulties that can be better treated by other means with a greater prospect of permanent results.

### DISCUSSION.

Dr. Donald Macrea, Council Bluffs, Iowa, mentioned a case in which the upper part of the cervix was perforated by a modified Goodell dilator in the hands of a young practitioner, and a portion of the intestine pulled through the opening and pulled off.

Dr. H. G. Wetherill, Denver, said the great dangers associated with the use of the curette were beginning to be appreciated both by the profession and laity, not only in the hands of the inexperienced, but in the hands of experts. He detailed a case which illustrated the ease with which the uterus could sometimes be perforated. A woman attempted to induce abortion by inserting an umbrella ring into the uterus; this went through the posterior vaginal wall, perforated the liver and the diaphragm, and was found in the right pleural cavity.

## Symposium on Gastric Ulcer.

Dr. H. D. Niles, Salt Lake City, Utah, presented the following conclusions: 1. Postmortem statistics, clinical experience and recent operating-room observations all tend to confirm the belief that neither the frequency nor the grave importance of gastric ulcer is fully appreciated by the profession generally, and the majority of cases are not recognized as such in life. 2. An earlier and more positive diagnosis means greater alertness in our observation and interpretation of symptoms, and more frequent exploratory operations. 3. In the history of every benign or malignant ulceration situated in a safely accessible region, there is always a time when the pathology can be corrected or favorably modified by appropriate mechanical means. 4. The recognized indications for operative procedures in gastric ulcer have been the symptoms produced by the remote resultant pathology, as hemorrhage, perforation, pyloric obstruction, cancer, etc., but our aim should be to make an earlier diagnosis and by timely and rational treatment prevent these later and more serious manifestations. 5. Taking into stricter account the local etiologic factors will undoubtedly aid us in the prevention, diagnosis and treatment of gastric ulcer. 6. The causative pathology deserves more consideration in the surgical treatment than it has yet received. 7. Perforation always demands the promptest surgical interference. 8. Hemorrhage from gastric ulcer is best treated by gastrojejunostomy. 9. Open or cicatrized ulcers near the pylorus always indicate rest for the parts and a sufficient outlet for the stomach contents. 10. A posterior gastrojejunostomy with sutures gives a minimum risk and the most satisfactory results, and hence is usually the operation of choice. 11. Our future advancement in the treatment must come from an earlier recognition and better understanding of the antecedent coexisting and resultant pathologic processes rather than from any further refinements in operative procedures.

### ETIOLOGY, SYMPTOMATOLOGY AND DIAGNOSIS OF GASTRIC ULCER.

Dr. Frank C. Davis, Des Moines, Iowa, said that clinically and pathologically gastric ulcer might be classified as acute, acute secondary and chronic. Each classification was expatiated on. Hematemesis is a sign of such unmistakable value that one only needs to exclude a few other sources for the blood to establish a diagnosis by it alone. The symptoms were detailed.

A conservative estimate of perforation places it at about 5 per cent. It occurs most frequently in females.

### PERFORATING GASTRIC ULCER.

Dr. Archibald MacLaren, St. Paul, Minn., said that perforating gastric ulcer was fully as common as extra-uterine gestation, and that when the eyes of physicians were opened to this fact, they would be able to see them, diagnose them early, and save many lives that were now lost. In this country he did not believe that the perforation cases reached the hospitals as often as they did abroad. His experience led him to believe that Dr. Richard Harte was correct when he said that rigidity or tension of the abdominal muscles was the keynote to the early recognition of peritoneal perforation from whatever source. The pain might subside, the temperature might not be elevated, but the rigidity continued even up to the end. He believed that many cases could be correctly diagnosed, as was proved by a few cases which he reported, and by the many cases which were constantly being published in the journals. He detailed three cases.

### DISCUSSION ON GASTRIC ULCER.

Dr. Charles W. Oviatt, Oshkosh, Wis., mentioned the case of a man, 62 years of age, a laborer, who had never complained of any symptoms of gastric ulcer. He had eaten a hearty meal, laid down on the lounge feeling perfectly well shortly after, but within an hour he rolled over on to the floor with agonizing pain. A physician was called, who gave large doses of morphin hypodermically, without any benefit, and the patient died within a few hours. Postmortem examination revealed a perforating ulcer in the posterior wall of the stomach, which seemingly had attempted to heal. There was no blood in the stomach, but the abdominal cavity was filled with stomach contents.

Dr. B. B. Davis, Omaha, said that stagnation accounted practically for a large proportion of cases, and without it there was no ulcer.

Dr. Leonard Freeman, Denver, detailed a case he observed some time ago, in which perforation occurred early in the morning, but rigidity of the muscles of the abdomen did not follow until 2 o'clock in the afternoon. This caused failure to recognize the case, and operation was done too late.

Dr. Charles H. Mayo, Rochester, Minn., said that after examining 1,100 stomachs by test meals, laboratory testing and physical examination, anemia was a very important factor; next, long-continued neurasthenic symptoms. Welch also found in an examination of 788 cases of ulcer of the stomach that only 28 occurred in the greater curvature, so that the greater proportion of them were found in the pyloric end of the stomach. Of cases of cancer of the stomach, Dr. Mayo had elicited a history of chronic ulcer covering a period of from one to fifteen years. His statistics showed 88 per cent. of gastric ulcer, and 12 per cent. of duodenal ulcer. The tendency was more and more to class the first two and a half inches of the duodenum as a part of the stomach. In 31 cases of acute perforation of the stomach and duodenum, 11 occurred in the duodenum in this first two and a half inches, and he had operated on 26 cases of ulcer of the duodenum.

Dr. M. L. Harris, Chicago, said the extensive experimental work of Fütterer showed it was impossible to produce gastric ulcer in an animal until the hemoglobin of the blood had been reduced below a certain point; that all lesions of the mucosa produced in healthy animals readily healed. When the hemoglobin is reduced below a certain point, producing a marked anemia, then these lesions develop into typical ulcers. These observations show the importance of an examination of the blood in these cases. The examination of the feces may show hematin crystals—a means of diagnosis in obscure cases.

### Symposium on the Treatment of Hematemesis by Gastro-enterostomy.

Dr. F. Gregory Connell, Leadville, Colo., classified the operative treatment of hematemesis into direct and indirect. Under direct he included (1) excision of the ulcer; (2) partial gastrectomy or pyloroplasty; (3) ligation of the principal artery; (4) cauterization or curettage of the ulcer; (5) ligation of the mucous membrane, and (6) ligation of all coats. Under the indirect he mentioned (1) gastro-enterostomy; (2) pyloroplasty, and (3) gastrotomy. The direct methods are not in common use, because of such objectionable features as the difficulty of locating the ulcer, the fact that the lesion is frequently multiple, the presence of firm and complicating adhesions, and the indistinct limitations of the pathologic tissue. The high mortality rate of some and the impracticability and unreliability of others have caused a general turning to the indirect method, as exemplified by gastro-enterostomy. The manner in which a gastro-enterostomy allows an ulcer to heal is well understood and practically settled, but as to this same operation acting as a hemostatic measure, no such substantial reasons as those advanced for the healing can be presented. While rest and drainage undoubtedly favor clotting and the cessation of hemorrhage from small blood vessels, it is difficult to understand how they can arrest hemorrhage from a large artery with a lateral opening.

Gastro-enterostomy is indicated in hematemesis (1) after a thorough search has failed to reveal the source of the hemorrhage: (2) where the source of the bleeding is discovered, but in such condition as to make direct treatment impracticable or impossible.

#### TWO CASES OF ACUTE HEMATEMESIS IN WHICH GASTRO-ENTEROSTOMY WAS PERFORMED.

Dr. Leonard Freeman, Denver, detailed two cases in which he performed posterior gastro-enterostomy, using the Murphy button. In one recovery was uninterrupted, but death followed recurrence about seven months later. In Case 2 the stomach showed no external sign of ulcer, and no internal exploration was attempted. The organ was markedly dilated with gas and fluid. Reaction from the operation was so satisfactory that hopes of recovery were entertained; but in spite of no recurrence of the hemorrhage, death occurred at the end of fifty hours, due apparently to the great loss of blood. Autopsy revealed an ulcer as large as a watermelon seed on the posterior wall, at the junction of the lower with the upper two-thirds of the stomach. A small atheromatous artery, plugged by a thrombus, could be seen in the floor of the ulcer.

#### DISCUSSION.

Dr. H. D. Niles believed that in cases of acute hematemesis any operative procedure would be attended with a high mortality. It was difficult to diagnose gastric ulcer from the external appearance of the stomach with sufficient accuracy to deal directly with it, at least, to determine on an operation. Gastro-enterostomy was not, in his opinion, an infallible remedy for the treatment of gastric hemorrhage. Unless one knew positively the source of the hemorrhage before opening the stomach, he thought it was better to perform the operation before hemorrhage was dangerous.

Dr. James E. Moore said the treatment of gastric hemorrhage by gastro-enterostomy at the present time was more or less empirical. The profession had not arrived at that point when positive statements could be made as to its value. The past history of cases showed that a considerable proportion of them not only recovered from immediate hemorrhage, but permanently without operation.

Dr. O. Beverly Campbell, St. Joseph, Mo., said, in regard to the closure of the opening made in gastro-enterostomy by the suture method, he had performed sixteen experiments on dogs. In 12 he used the Kocher method of suturing, and in all of them he did an anterior gastro-enterostomy. The opening in each instance was large. The dogs were reoperated on at periods of from three to six months, and at the end of three months in six cases the opening was reduced to such an extent that the index finger could not be passed through it without a little force. In six of the cases there was almost total obliteration of the opening at the end of six months. In four there was a slight opening through which only a small probe could be passed. A vicious circle was established in 40 per cent. of the cases. These experiments showed a tendency, where there was no obstruction at the pylorus, for the opening to close, whether it was made with the Murphy button or by the suture method. A larger opening was obtained if the Connell suture or the Kocher suture was used, and in every case the speaker made a rather large opening. Six dogs, in which a vicious circle was established, began to fail in flesh at the end of about two months, and at the end of the third month they were opened and a vicious circle found. In every instance there was more or less narrowing of the opening.

Dr. Charles H. Mayo reported a case in which gastro-enterostomy failed to arrest hemorrhage. During the past year he operated on a man, 40 years of age, who gave a history, extending over a few years, of occasional stomach disturbance and vomiting of blood. By the laboratory test a little blood was found in the stomach. At the operation, in examining the stomach, he did not find any external evidence of the ulceration. The stomach was dilated. He did a gastro-enterostomy, but there was more hemorrhage after it than before, and the man died at the end of four days. He was very anemic at the time of operation. At the autopsy the intestines were found filled with blood. The gastro-enterostomy was a posterior one, after the Mikulicz method, and the line of suturing was perfect. There were no large ulcers in the stomach, but there were two or three points of erosion.

Dr. D. S. Fairchild said a distinction should be made between chronic gastric ulcers which bled and fissure ulcers which sometimes gave rise to profuse hemorrhage. The chronic ulcers could be treated by gastro-enterostomy, but in fissure ulcers, where the hemorrhage was considerable, gastro-enterostomy was not sufficient, and it became necessary to dissect the ulcer out. A case was narrated in point.

Dr. Connell had had recently three cases of acute hematemesis under observation. One bled very profusely. Operation was advised, but refused, and it was thought the patient would die. But she recovered. There were no signs of ulcer. The second case was that of a child, four years of age, who had acute hematemesis. Operation was refused, and the child died. The third case he operated on, having in mind Moynihan's advice, that it was unnecessary to search for the bleeding point, as gastro-enterostomy would cause a cessation of the hemorrhage. He operated, but the patient died. From the postmortem examination in this case he felt confident that had he made a careful examination of the stomach with the object of finding the bleeding point, he would have found it, and had the ulcer been dissected out, in all probability the patient would have recovered.

Dr. Freeman said there were two kinds of cases on which the surgeon had to operate: First, those in which the surgeon could take time and search for the ulcers; and if he found them, he could deal with them accordingly. The other class was illustrated by the two examples cited in the paper.

---

## Therapeutics.

**[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]**

### Scrofula.

In the treatment of scrofula, so states the *Med. Press*, cod-liver oil should be given during the winter months if the stomach can retain it. In the summer, the syrup of the tannate of iodin or the following may be given:

| | | | | |
|---|---|---|---|---|
| ℞. | Calcii iodidi | ʒiss | 6 | |
| | Aq. calcis | ℥ii | 60 | |
| | Aq. menth. pip. | ℥iv | 120 | |

M. Sig.: One teaspoonful in a small amount of water twice daily after a meal.

Every second day a bath should be taken, the water containing sodium bicarbonate two ounces (60.) and sodium chlorid thirty-two ounces (960.). The body should receive a thorough rubbing daily, after which the following should be applied:

| | | | | |
|---|---|---|---|---|
| ℞. | Eau de cologne | | | |
| | Spts. lavendulæ, āā | ℥iii | 90 | |

M. Sig.: To be rubbed thoroughly over the body.

The diet should be rich in fats and phosphates. Consequently the patient's food should consist mainly of milk, eggs, farinaceous compounds, meat, chicken and dry vegetables. The country and seaside are better locations for these cases.

### Neurasthenia.

In the *Med. Press*, M. Albec outlines the following treatment of neurasthenia: Suppress as much as possible the cause of the nervous exhaustion by withdrawing the patient from all business and enjoining strict rest of mind and body. He should be instructed to retire early and rise late. Every third day a bath should be ordered lasting for fifteen minutes, followed by a massage; this may be alternated with static electricity, placing a negative pole in communication with the patient.

As general tonics the following combinations are recommended by the author:

| | | | | |
|---|---|---|---|---|
| ℞. | Tinct. nucis vom. | | | |
| | Tinct. conine, āā | ʒi | 4 | |
| | Tinct. calumbæ | | | |
| | Tinct. gentianæ, āā | ʒiss | 6 | |
| | Essentiæ anisi | m. x | | 65 |

M. Sig.: Twenty drops in water before each meal.

During the meal, or following it, a combination similar to the following is recommended taken in wine:

| | | | | |
|---|---|---|---|---|
| ℞. | Strych. arsenatis | gr. 1/60 | | 001 |
| | Calcii glycerophos. | gr. v | | 30 |
| | Syr. aurantii | ʒi | 4 | |

M. Sig.: At one dose in a wineglassful of wine after each meal.

### Sodium Sulphanilate in Exophthalmic Goiter.

Kirnberger, according to an abstract in the *N. Y. and Phila. Med. Jour.*, recommends the sodium salt of sulphanilic acid in the treatment of exophthalmic goiter. He treats it in this manner on the hypothesis that the disease arises from an excessive production of iodothyrein by the thyroid gland. The preparation may be given in one of the following forms:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi sulphanil. | ʒi-ʒiss | 4-6 | |
| | Sodii carb. | ʒi | 4 | |
| | Aq. destil. | ℥ix | 270 | |

M. Sig.: From three to five dessertspoonfuls daily; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Sodii sulphan. | ʒi-ʒii | 4-8 | |
| | Aq. destil. | ℥ix | 270 | |

M. Sig.: Six dessertspoonfuls daily.

According to the author this preparation produces rest and vigor and causes the patient to increase in flesh, and it very perceptibly diminishes the tachycardia.

### Heroin to Relieve Cough.

The following combination containing heroin is recommended by Haas and de Santos in *Buffalo Med. Jour.* for the relief of cough:

| | | | | |
|---|---|---|---|---|
| ℞. | Heroin hydrochlor. | gr. 1/16 | | 004 |
| | Ammon. hypophos. | gr. iii | | 20 |
| | Balsami tolutani | gr. iv | | 25 |
| | Ext. hyoscyami. | gr. i | | 06 |
| | Glycerini q. s. ad | ʒi | 4 | |

M. Sig.: To be taken at one dose and repeated every two, three or four hours.

They recommend it in the treatment of pertussis, pulmonary tuberculosis, asthma and in acute bronchitis.

### Local Anesthesia of the Pharynx and Larynx in Tuberculosis.

According to Pollatschek in *Internat. Med. Mag.*, changes in the upper-air passages, especially those in the larynx, are important factors in pulmonary tuberculosis. In his opinion the cause of the cough in tuberculosis can be found in the upper-air passages in fully 70 per cent. of the cases. He has employed, in a great many cases, anesthesin locally for the relief of the conditions in those passages, and with very satisfactory results. He uses the following emulsion injected directly into the larynx or in the form of an inhalation:

| | | | | |
|---|---|---|---|---|
| ℞. | Menthol | gr. xxiiss | 1 | 50 |
| | Pulv. gummi arab. | | | |
| | Ol. amygd. dulcis. | | | |
| | Aquæ destil, āā | ʒiiss | 10 | |
| M. | Ft. emulsio; add: | | | |
| | Anesthesini | gr. xlv-ʒi | 3.-4 | |
| | Spts. vini conc. | ʒx | 40 | |
| | Aq. destil. | ℥ii | 60 | |

M. Sig.: Inject into the larynx.

The anesthetic effect lasts from three to thirty hours, and in some cases longer, and no symptoms of intoxication have been noticed.

The following combination containing anesthesin may be employed as an inhalation:

| | | | | |
|---|---|---|---|---|
| ℞. | Anesthesini | gr. xlv | 3 | |
| | Spts. rectif. | | | |
| | Aq. destil., āā | ℥ii | 60 | |

M. Sig.: As an inhalation.

For local application to the pharynx the following is serviceable:

| | | | | |
|---|---|---|---|---|
| ℞. | Anesthesini | ʒii | ·8 | |
| | Mucil. acaciæ | ʒiv | 15 | |

M. Sig.: To be painted on the painful areas by means of a swab.

To relieve the pains caused by external wounds on different parts of the body, such as by burns, etc., anesthesin is said to be of value applied in the form of an ointment:

| | | | | |
|---|---|---|---|---|
| ℞. | Anesthesini | ʒi-ʒii | 4-8 | |
| | Lanolini | | | |
| | Liq. petrolati, āā | ℥i | 30 | |

M. Ft. unguentum. Sig.: Apply locally; or it may be used as a dusting powder as follows:

| | | | | |
|---|---|---|---|---|
| ℞. | Anesthesini | ʒi | 4 | |
| | Bismuthi subgal. | ʒiss | 6 | |
| | Pulv. amyli | ℥ss | 15 | |

M. Sig.: Apply locally as a dusting powder.

Dr. E. Fletcher Ingals, after using this preparation a satisfactory length of time, states that the anesthetic effects produced on unbroken membranes are slight, but it has proved to be of benefit as an anesthetic on the broken surfaces, after cauterizations of the nose and tonsils.

### Methylene Blue in Insomnia of the Insane.

After studying the effects of methylene blue in several cases, including the various psychoses of the insane, Zaitzer and Taporkov, in *Merck's Archives*, states that this preparation is not only a sedative in maniacal excitement, but is also a good hypnotic in insomnia without maniacal excitement. It is superior to other hypnotics in being free from after-effects. They administered it hypodermically in doses ranging from grain one half (.03) to grains two (.12) or per os in three-grain (.20) doses three times a day, combined with pulverized myristica.

### Scabies.

The following formula is recommended by Fournier in the treatment of scabies:

| | | | | |
|---|---|---|---|---|
| ℞. | Potass. carb. | ℥ss | 15 | |
| | Sulphuris sublim. | ℥iss | 45 | |
| | Mucilaginis tragacanthæ | gr. viii | | 50 |
| | Glycerini | ℥iiiss | 100 | |
| | Essentiæ menth. pip. | | | |
| | Essentiæ lavendulæ, āā | m. x | | 65 |

M. Ft. unguentum. Sig.: Apply locally night and morning.

The following combinations are also of service in the treatment of scabies:

| | | | | |
|---|---|---|---|---|
| ℞. | Sulph. precip. | ℥ss | 15 | |
| | Naphthol resublim | ʒss | 2 | |
| | Lanolini | | | |
| | Liq. petrolati, āā | ℥ss | 15 | |

M. Ft. unguentum. Sig.: Apply locally twice daily; or:

| | | | | |
|---|---|---|---|---|
| R. | Menthol | gr. xx | 1 | 30 |
| | *Adipis benzoinati* | ℥ss | 15 | |

M. Ft. unguentum. Sig.: Apply locally night and morning.

Hyde recommends that one of the following combinations be substituted for the ordinary sulphur ointment in the treatment of scabies:

| | | | | |
|---|---|---|---|---|
| ℞. | Liq. styracis | ʒi | 4 | |
| | Liq. petrolati | | | |
| | Ol. olivæ, āā | ℥ss | 15 | |
| | Balsam. Peruv. | ʒiiss | 10 | |
| | Spts. sapon. viridis | ʒv | 20 | |

M. Ft. unguentum. Sig.: Apply locally; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Potass. sulphuret. | ʒiiss | 10 | |
| | Saponis alb. | ʒx | 40 | |
| | Ol. olivæ | ʒii | 8 | |
| | Ol. thymi | m. viii | | 50 |

M. Ft. unguentum. Sig.: For local application.

### Prurigo Gravis.

The following combination is recommended by De Beurmann in *Rev. Fran. de Med.* as of value in the treatment of prurigo Hebræ:

| | | | | |
|---|---|---|---|---|
| ℞. | Pulv. camphoræ | | | |
| | Picis liquidæ, āā | ʒi | 4 | |
| | Sulphuris | gr. xl | 2 | 65 |
| | Olei gynocardiæ (chaulmoogra) | m. xv | 1 | |
| | Liq. petrolati | ʒv | 20 | |

M. Ft. unguentum. Sig.: To be applied locally.

## Medicolegal.

**Physicians Only May Complain of Discriminations.**—The Court of Civil Appeals of Texas, in the case of Sweeney vs. Webb, wherein the validity of the local option law was assailed, says that one of the contentions was that the act denied equal protection of the law, and was therefore unconstitutional, because one section forbids the prescribing of intoxicating liquors by any one who does not follow the practice of medicine as his principal and usual calling. But the court says that the only discrimination shown was between physicians who practice medicine occasionally and those who make it their principal calling, and since the parties suing were not physicians, they could not successfully complain of that clause.

**Privilege Does Not Cover Prescriptions and Druggists.**—The First Appellate Division of the Supreme Court of New York says that, in the personal injury case of Deutschmann vs. Third Avenue Railroad Company, the company called as a witness a druggist, who testified that he knew the party suing, that he had filled prescriptions for her, identified the prescriptions made by a physician who had treated her, and stated that he had filled them for her. The prescriptions were then offered in evidence, and the party objected to them on the ground that they constituted a confidential communication of the physician who gave them, and were therefore inadmissible in evidence; and such objection was also urged to the testimony given by the witness. These objections were overruled, and the evidence given by the witness was received, as were also the prescriptions. In holding that there was no error in this the court says that it is to be borne in mind that at common law the mouth of the physician was not closed as to any matters which were pertinent and competent on the issue, the subject of investigation. And it is always competent for the patient himself to make disclosure of any matter which has been communicated by the physician. The prohibition of the statute relates to the physician alone. It is his mouth that is closed. And the physician's mouth is only closed as to communications necessary to enable him to act in a professional capacity toward the patient. The necessity of having physicians' prescriptions filled by druggists may furnish a reason for the legislature to say that public policy will interpose to prevent them from making disclosures of the information thus obtained, but it is enough now to say that the statute in question has no application to such a situation. Having parted voluntarily with the prescriptions by delivery of them to a third person, the party suing could not exclude the testimony offered from such a source. Therefore, no error was committed in receiving in evidence the testimony of the druggist, and accompanying the same with the prescriptions which the party suing had delivered to him. Undoubtedly the mouth of the physician would be closed, as he could at no time either authorize another to disclose, or disclose himself, any communications made to the party suing, whether oral or written. His certificate filed in a public office pursuant to the requirements of a statute may not be given in evidence, and is within the prohibition of the statute, as it remained at all times his communication of matter which he received in a confidential capacity, and is therefore inadmissible. But that rule was without application here, for the evidence was of a disclosure made by the party suing of the physician's communication to a third party, and that, being her voluntary act, authorized proof of the matter disclosed. Evidence from experts to show that the prescriptions called for specifics for syphilis was also competent for the same reasons. The party suing having refused to waiver her privilege and permit a physician to testify, the court thinks, in view of the fact that the statute is silent on the subject, that the jury were not precluded from considering the entire attitude of the party, and drawing such inference therefrom as was fairly deducible from the situation which had been created.

**Validity of Contract Not to Practice in Certain Place.**—In the Illinois case of Ryan vs. Hamilton, it appeared that the party sued, a physician, signed a contract agreeing never, either separately or as one of a firm, to practice general medicine in or within eight miles of a certain place, without the consent of the other party, while the latter practiced in said place or within eight miles thereof (unless forced to by some unforeseen circumstances, in which case he agreed to pay the other party a reasonable sum). The Supreme Court of Illinois says that the principles of law applicable to this case are the same as those governing the specific performance of contracts in restraint of trade. That contracts in general restraint of trade are generally held to be illegal is beyond controversy. But the rule admits of well-defined exceptions, among which are such contracts as in this case. Contracts of this class, where the limitation as to territory is reasonable, and there exists a legal consideration for the restraint, are valid and enforceable in equity, and in such cases relief by injunction is customary and proper. In all such cases it is not the business of a court to inquire whether the consideration is adequate, or of equal value to that which the party loses by the restriction; it is impossible for courts to tell how valuable to the complainant or how injurious to the defendant may be the restraint sought. It is sufficient to uphold such contracts if the court concludes that there is some legal consideration; but the adequacy of the consideration is within the exclusive dominion of the parties where they contract freely and without fraud. In this case the consideration for the contract appeared to be the purchase from a partner of the physician signing the contract certain personal property of the former, which the firm had used in and about their practice, so that the signer of the contract might be enabled to carry out a purpose he had of becoming a specialist and re-entering into business with his former partner. The court holds that it could not be reasonably contended that there was no consideration though the signer received no money. Moreover, the court thinks it sufficient that the injured party showed that the signer of the contract returned and engaged in practice after making an effort to form a partnership with him and an effort to purchase his (the injured party's) business, and, if there was anything other than the ordinary business motives that prompted the signer of the contract, it was the latter's duty to have disclosed it, to be protected by the provision excusing him if forced by some unforeseen circumstances. Nor does the court consider this provision too indefinite to permit of the enforcement of the contract. It says that in interpreting such writings it is the duty of courts to give them a reasonable and sensible construction, and, as far as may be, carry out what was the intention of the parties. The modern trend of the law has been to recognize a person's property right in the good will of a business built up by him, and the tendency is to remove the restrictions formerly placed on its sale. And, according to well-established rules of law in this and other states, the court regards the restrictions imposed by the contract in this case as reasonable.

*December 26.*

1 *Tumors of the Ponto-Medullo Cerebellar Space. Acoustic Neuromata (Central Neurofibromatosis) Joseph Fraenkel and J. Ramsay Hunt.
2 *The Present Status of the Treatment of Lateral Curvature Jacob Teschner.
3 *Intestinal Fermentation as It Interests the Surgeon. Robert T. Morris.
4 *Submucous Resection of the Nasal Septum. Felix Cohn.

1. **Tumors of the Ponto-Medullo-Cerebellar Space.**—This condition is not a rare one according to Fraenkel and Hunt. The underlying active factor in all the cases is a teratologic one. Five cases are reported; the symptomatology is that of tumor of the posterior fossæ of the skull preceded by symptoms referable to disease of the fifth and eighth nerves. The cases all show the common origin from the cranial nerve trunks. Pathologically they are neurofibromata, pure or in various stages of metamorphosis and transformation. The locality is in all forms similar—the angle formed by the junction of pons, medulla and cerebellum; symptomatically analogous. The authors remark that the certainty of locality, the essentially benign nature of the growths and their loose attachment, make them favorable ones for surgical interference.

2. **Lateral Curvature.**—Teschner criticises the authorities for their neglect of his method of gymnastics in the treatment of lateral curvature, and calls the attention of physicians to the necessity of carefully and understandingly examining cases of faulty posture and gait and the advisability of proper treatment. He explains the difference between his system and ordinary gymnastics, and the proper learning and directing of them.

3. **Intestinal Fermentation.**—The surgical factors in intestinal fermentation are noted by Morris, who includes among them intestinal adhesions, especially about the appendix and cecum. He remarks that we are apt to overlook other adhesions such as those about the sigmoid and gall bladder which are also of importance. Normal involution of the appendix is also a cause of intestinal fermentation in his opinion. Reflex irritation from contraction of the connective tissue and injuring of the terminal filaments of the entrapped nerves is liable to produce such disorders. Still other causes are loose kidneys, and he credits a large group of cases of intestinal fermentation to eyestrain. Those who have suffered from chronic constipation since childhood he thinks are victims to the presence of hypertrophied rectal valves. In conclusion he remarks that he is curious to know what proportion of intestinal fermentations are really medical cases, and not curable by surgical resources.

4. **Submucous Resection of the Nasal Septum.**—The method recommended by Cohn is that of submucous resection, the operation of which is described. He uses a weak cocain solution and adrenalin in most of his cases, and usually places his patient on his back with head slightly raised and chin depressed, the head slightly turned away from the deviated side, the nostrils being held back by retractors. A slightly convex incision is made through the whole length of the mucous membrane as near to the point of greatest convexity as possible, and only through the membrane. The mucous membrane is then held back with a small, sharp hook and the cartilage, after being as much exposed as possible, is nicked and gradually separated from the mucosa of the opposite side. After it has been as fully freed as it can be, care being taken not to dislocate it, an incision is made parallel to the ridge of the nose, in order to prevent external deformity, and a second incision made below and the cartilage finally dissected out posteriorly. The first piece usually embraces the greater portion of the protuberating cartilage. The still projecting pieces must be removed seriatim, working from before backward, if necessary even removing the bony portion with small bone forceps. An occasional reversing of the mucous membrane is the best guide as to the amount to be removed. After the cartilage has been removed the mucous membrane is carefully replaced, and, if required, one or two sutures may be added. The nares are then lightly packed with gauze and the patient kept in bed for a day or two with ice applications over the nose and a change of dressing every twenty-four hours for two or three days. After that no further treatment is usually required except an ointment or spray to prevent the formation of crusts. Of course those cases that can be operated on by simpler measures with the knife, saw, chisel, or drill, for instance, should be excluded. The results of submucous resection are uniformly excellent. After-treatment is unnecessary.

5. **Bronchopneumonia.**—Conner discusses some of the forms of bronchopneumonia, noticing the general predisposing causes, of which he puts age among the first, the season, in which it seems to follow the same rule as lobar pneumonia, and the previous condition of health, which is exceedingly important. Of secondary bronchopneumonia measles is usually the first associated cause, but influenza, diphtheria and scarlet fever as well as bronchitis of children are to be mentioned. As a complication of debilitating disease it is especially seen in old age, though it may occur at other ages. Aspiration pneumonia is common in conditions of stupor and unconsciousness, when sensibility of the larynx is reduced, or swallowing is difficult, and irritating matter passes down the wrong way. The bacteriology is discussed at length. In about 50 per cent. of the cases of primary bronchopneumonia, the pneumococcus is found

either alone or in conjunction with other germs, most commonly streptococci. Next in frequency comes the streptococcus, and after that the pyogenous staphylococci, Friedreich's bacillus, the influenza bacillus, etc. In secondary bronchopneumonia, the bacterial list includes the same forms, together with others, such as those of diphtheria, typhoid and the *Diplococcus meningitidis*, etc. While the pneumococcus is the one perhaps most frequently found, it is much less common than in primary cases, and recent researches have shown the pure culture of diphtheria, influenza and other bacteria in cases following those disorders. In typhoid bronchopneumonia, the typhoid bacillus does not seem to be found in the lungs as a rule, and the disease from this cause is apt to be a secondary or heterologous infection, as infection through the air-passages by the typhoid bacillus is very unlikely. In tuberculous bronchopneumonia the pneumococcus seems to be frequently found. It appears to be the belief of many that the tubercle bacillus is responsible only for the caseation which follows the infection and that the pneumococcus or streptococcus is the active agent. In bronchopneumonia following conditions other than the infectious diseases, the streptococcus and staphylococcus have been found, and the bacillus coli in a small percentage of cases. The significance of this latter seems to be that it indicates only a postmortem or at most an agonal invasion and is not a causal agent. Other micro-organisms than bacteria may occasionally be associated with bronchopneumonia, such as streptothrix. The question whether or not the bronchi in health contain bacteria has not been definitely settled, the weight of evidence seems rather to be against it. It seems probable that such germs are usually absorbed by epithelial cells and destroyed. They may, however, under abnormal conditions find congenial soil in the bronchial tubes.

6. **Tuberculosis.**—Cobb discusses the reasons why the apices of the lungs are most frequently the primary seat of tuberculosis. He concludes that the germs are taken in through the blood current, and that the constant deposit in the apices of the lungs lies in the fact that the pressure from the front by the great veins and lymph vessels in the angles of the neck causes enough suction to create a counter lymph current and an area of lymph stasis in the apices of the lung where a bacillus will become much more quickly arrested.

7. **Nose and Throat Operations.**—Sinexon calls attention to the need of caution in nose and throat operations and enumerates from the literature many cases where serious and even fatal accidents have followed trifling operations on the nose and throat. The possibility of fatal hemorrhage is to be considered in these cases. Even epistaxis has been known to be fatal. In intubation, too, the possibility of the membrane extending further down the trachea than the length of the tube employed, and being pushed down below it is a thing to be thought of. It is imperatively necessary that one should be prepared to perform tracheotomy in all cases where intubation is employed.

9. **The Laryngeal Complications of Typhoid.**—After a detailed discussion of the subject and a report of cases, Dupuy concludes that the 256 collated cases, reported in the last fifty-eight years, which for evident reasons are only approximately correct, afford eloquent proof that the subject of typhoid affections in the larynx calls for general recognition.

> Evidence, bacteriological and clinical, strongly supports the view adopted by the majority of observers, that the laryngeal involvement in most instances is a direct typhoid infection.
>
> A high death rate, as shown by statistics, when this complication exists, teaches the salutary lesson of always examining the larynx when the danger signals of hoarseness, dyspnea or dysphagia set in.
>
> The favorable results which follow operative interference offer such a contrast to the high mortality without operation that there can be but unanimity of opinion as to its propriety.
>
> Tracheotomy is the most approved, because in most cases the only possible surgical procedure which can save life.

10. **Baldness.**—The cause of baldness is attributed by Gilbert to tight hatbands. He remarks that women and savages do not suffer from the condition, and suggests the use of small cork fenders around the hatband, avoiding pressure to certain parts or sections, leaving the intervening space free for normal blood supply and free ingress and egress of air from the hat chamber above. This would, of course, require a little larger hat than usually worn, but no larger than is demanded by the ordinary corrugated sweatband.

11. **Typhoid Fever.**—Bass has used castor oil in typhoid fever in a large number of cases and finds that it has a valuable influence on the condition of the bowels, preventing diarrhea and also controlling the temperature by preventing the absorption of poisons from the undigested, decomposing bowel contents. It is better than other purgatives for it goes through the bowels unchanged and disturbs the patient least. The method he thinks best is to begin with a dose of pure castor oil every twelve hours, regardless of the stage of the disease. The dose should be so regulated as to cause one or two actions, varying from one to eight drams, depending on the patient, the stage of the disease and the condition of the bowels. He continues it through the whole disorder.

14 *Diffuse (Combined) Degeneration of the Spinal Cord. E. W. Taylor and G. A. Waterman.
15 *Historical Notes on the Laws Governing Civil Malpractice in the Ancient Times and the Middle Ages. Charles Greene Cumston.
16 The Bitzer Homicides. George P. Twitchell.
17 *Malaria and Mosquitoes of Worcester. A Year's Observations on the Habits of Culex and Anopheles. (Concluded.) William W. McKibben.

14. **Diffuse Combined Degeneration of the Spinal Cord.**—Two cases of this syndrome are reported by Taylor and Waterman, the first showing marked arteriosclerosis in the brain—internal capsule, diffuse quasi-systemic degeneration of the cord involving the dorsal and lateral tracts, most marked in the thoracic region, and nerve roots undegenerated as also the gray matter, no cachexia or anemia. In the second case there was diffuse degeneration in a patient dying with symptoms of pernicious anemia, the lesions sharply limited to the dorsal and lateral columns of the cord, but not anatomically confined to the neuron systems. There were no noteworthy alterations of the nerve cells of the ventral horns and no general changes in the blood vessels, either without or within the cord, and the nerve roots were unaffected. Both cases belong in the general group of diffuse (combined) spinal degenerations; those in the first case being much more diffuse than in the second, which is noteworthy in its relation to the fact that cases associated with anemia have been declared to be more diffuse than others. The authors are inclined to think that the various concomitant conditions associated with this type of nerve degeneration are not etiologically significant, but that there is some unknown cause, which they may call a toxemia. They review the opinions of various authorities on the subject and hold to their previously expressed opinion that no fundamental characteristics of the lesion have been found dependent on different causes, and that for the present diffuse or diffuse (combined) degeneration is as near an exact designation of the anatomic conditions as can be made. This, of course, excludes other cases, such as those of Friedreich's disease or paresis, where true systemic degeneration of the lateral and dorsal tracts may take place. In conclusion they remark that cases which present during life a high degree of spasticity with slight ataxia seem to be more chronic in their course than those where the ataxic symptoms are more pronounced and early.

15. **Malpractice.**—Cumston's paper is an interesting historical review of the recognition of civil medical liability under the law. It shows that it has been sustained by the courts at all former times. He does not take up the question of criminal malpractice.

17. **Malaria.**—McKibben finishes his article on malaria at Worcester, Mass, showing how general it has become, and how directly its origin is traced to infection by mosquitoes and the neglect of local authorities in meeting the case.

18. **Neuritis.**—Pritchard reports six cases illustrating as many different types, the first being a neuritis of the seventh nerve. He points out the difference between central and peripheral facial palsy, and describes the treatment. He has much faith in electricity in these cases. Sciatica is next mentioned; here he would advise the use of morphin where it is indicated, as preferable to other drugs that have been recommended to relieve the patient. As regards nerve stretching or surgical interference, he advises extreme conservatism and mentions a case where paralysis followed operative measures. He says do not forget in all cases to examine for diabetes or gouty states or lead poisoning, the blood for malarial and other parasites, the pelvis for tumors and uterine disease, and the bones for hyperplastic inflammatory disorders, the blood vessels for aneurisms or varicosities, all of which may aggravate sciatica. The third form described is intercostal neuritis associated with zoster. He dispenses with the use of local treatment in these cases as a rule, and regards the application of galvanism through a bare metal electrode as often positively harmful. Neuritis of the fifth nerve or tic douloureux is described at considerable length. He calls particular attention to the habit tendency. The nerve function when perverted is particularly prone to habit tendencies. Starting in some local definite cause or in some equally positive constitutional state, he says, a neurosis, motor, sensory, or vasomotor, quickly develops the habit tendency, which results in a continuation of the neurosis after the cause has ceased or has been removed surgically or otherwise. He protests against radical surgical procedures in this form, and says be sure that your patient has a trial of everything else and that the condition can not be made worse before you resort to them. He mentions the castor-oil treatment, which has occasionally been followed by relief, and it should be tried if other more legitimate methods fail. Dana's method with progressive massive doses of strychnia he has found in a few cases to have a marvelously happy result, but if no result is obtained by the fifth day and reaching doses of 1/12 of a grain, it is useless and sometimes dangerous to carry the treatment further. His own plan of treatment is, after having antagonized all local and constitutional predisposing causes, to have recourse to the constant current guided as to quantity by the meter. Mild currents with long seances is a safe general rule, and he puts his patients on full doses of hyoscin hydrobromate, 1/100 to 1/50 of a grain, two or three times daily, and follows this with the anodyne prescription of sodium salicylate, 3 gr., quinin 1 to 2 gr., codein, 1/4 to 1 gr. One such every three, four or five hours. Heroin may be used instead of codein. Lastly, he mentions traumatic neuritis and remarks on its medicolegal bearings. In conclusion he summarizes the following points: 1. The importance of functional rest in all cases of neuritis often to the extent of mechanical enforcement. 2. The value of forced nutrition, especially with fats, constitutionally and locally. 3. His great confidence in electricity and massage, neither of which, however, should be used empirically, and both of which require the utmost nicety of personal adjustment. 4. The maintenance of an equable surface temperature in all forms of sensory neuritis. 5. The recognition of the neurotic habit, tendencies and predispositions, and recognition of the fact that is almost axiomatically true that all cases of neuritis, except perhaps the traumatic and mechanical, are associated with and often dependent on states of altered metabolism and perverted nutrition, to which recognition is logically correlated the necessity of tonic, alterative and nutritional measures.

19. **Adenoids.**—Gradle first remarks on the adenoid face, which is not always significant, as it may occur with other conditions, and may be wanting where the pharyngeal tonsil is enlarged enough to be of clinical importance. Most patients breathe easily enough while standing, but on lying down the difficulty begins. He is inclined to attribute the greater destruction during sleep to the turgescence of the posterior ends of the turbinals—the inferior and also to some extent, the middle. This also explains the characteristic adenoid "dead" voice. Aprosexia, or the lack of ability to give attention, seems to depend on the size of the hypertrophy and not on the obstruction by vascular distension. In all his cases it occurred with large tonsils. He thinks it has not been sufficiently emphasized that most of the mischief from adenoids results from inflammatory attacks of the tonsil when enlarged. The inflammation, often subacute from the start, extends into the nasal passages, to the ears and not rarely to the bronchi. He is not inclined to think that mechanical stoppage of the Eustachian tube occurs as a rule. Eustachian catarrh has usually a favorable prognosis, and he thinks the danger to hearing has perhaps been a little overstated, but the relation of adenoids to eye affections has not received the attention it deserves. In children suffering from phlyctenular keratitis a large majority have hypertrophied pharyngeal tonsils, and he has followed the practice of removing the adenoids in such cases with good results. The effect on the general nutrition is marked, and it almost seems that some adenoids exert a poisonous influence. He has seen anemia improve rapidly after operation. In older children the results are not quite so satisfactory because of the hyperplastic lesions in the upper-air passages often induced by the adenoids. The cause of adenoid growth of the pharyngeal tonsil he found in the repeated attacks of coryza in predisposed subjects, and the history of his cases confirms this belief. The relation of adenoids to scrofula is mentioned as a not yet fully solved problem, as apparently scrofulous children are more liable to these conditions. He thinks the indication is to remove any enlarged pharyngeal tonsil that causes disturbance, and he regards a tonsil as morbidly enlarged whenever it projects above the surrounding mucous membrane. Operation in his hands is usually performed without narcosis, which he thinks would make it a rather more severe procedure. If an anesthetic is to be used nitrous oxid gas is best, but outside of multiple tonsillotomy the adenotome enables the operator to do his work as well and more quickly with a wide-awake child than a narcotized one.

20. **Dysmenorrhea.**—Dilatation and curettage is the method here described by Parke, which is, he thinks, a simple operation, not, however, wholly unattended with danger. It should not be undertaken without physical examination to determine the absence of contraindications, and without the greatest care as to antisepsis and the avoidance of accidents.

21. **Stomach Inflation.**—Three cases of death following stomach dilatation for diagnostic purposes with $CO_2$ gas are reported by Behrend. In the first case death resulted from hemorrhage at the base of the ulcer; in the second case the patient was prostrated from its use and never rallied, dying the following day. It was one of carcinoma of the esophagus and stomach with cholelithiasis and pericholecystitis in a very debilitated patient. The third case was in a man suffering from carcinoma of the esophagus and the patient was semi-conscious from the administration of the gas until the time of his death. He thinks that these cases show that the use of carbonic acid gas in inflating the stomach is rather a serious operation, infinitely more dangerous where there is a disease of the esophagus and the cardiac end of the stomach. This may be due to pressure exerted within the narrowed limits. If used, the procedure must be employed only with discretion and in selected cases.

22. **Kidney Diseases.**—The title of this article explains it. Lower calls particular attention to the cryoscopic method as an important supplement to other methods of examination and as the best-known way at present of determining the functions of the kidney.

24. **Tuberculosis.**—Huber recognizes the hereditary tendency to tuberculosis manifested chiefly by what he calls a scrofu-

lous temperament with pallid skin and flabby flesh with often a chronic blepharitis; phlyctenulæ are frequent, the nose is large and broad, adenoids and hypertrophied tonsils are common, so that the patients are frequently mouth-breathers; there is generally a sluggish, torpid metabolism. Besides these anatomic defects he notices also the narrow chest and projecting shoulder-blades, the small respiratory muscles as well as the defective development of the aorta, congenital heart lesions, small heart, anemia, chlorosis, slow teething, deficient ossification, and so on. Other defects are functional in character, and this is an important point, as functional rather than anatomical modifications are transmitted. The latter are more dependent on the former. He also recognizes the possible transmission of tuberculosis congenitally, and questions the inhalation theory of its transmission, believing that the alimentary tract plays a much more important part in the spread of the disease. Faulty metabolism plays an enormous part in predisposing the tissues. The decomposing nitrogenous matters in the body afford culture ideal media; impaired circulation, alcohol with its accompanying poverty and ill health are also important factors. He notices also the subtle relation between insanity and tuberculosis, the bad diet such as is customary in the country, intermarriage, the constipation habit, etc. Tuberculosis is prone to follow on other diseases, such as bronchitis, influenza and neglected colds, and there are a number of trades which seem to stand in a direct causative relation to it, also direct injuries from contusions, wounds, etc. Psychic factors are also to be considered, such as excitability, overwork, shock, etc., deranging the functions. He considers that the bacillus itself is not the only thing to be combated, but thinks that its discovery has benefited matters on the whole by leading to the adoption of principles of prophylaxis and sanitation. While there are some immunizing serums which promise much, he remarks that they will never exceed in value such immunizing agents as fresh air, sunlight, cleanliness, well-drained and ventilated houses, good food and good hygienic measures.

25. **Ligation of the Internal Jugular Vein in Lateral Sinus Thrombosis.**—The advisability of ligating the internal jugular in lateral sinus thrombosis is discussed by Oppenheimer, who notices Jansen and Brieger's views, and reports cases where it was indicated and performed. The most difficult cases in which to determine whether to ligate or not are those in which no operation has as yet been performed on the sinus, especially when pyemic symptoms are not well marked or the vein itself does not give indication of septic or thrombotic changes. Where the infection has extended into the jugular vein and resulted in suppurative phlebitis, the vein should be heated as low down to the clavicle as possible, the second ligature placed high up and the entire vein removed between them. He considers that the presence of a high temperature, and rapid remissions, quick alterations and repeated rigors are very important symptoms, and beginning or well-marked neuroretinitis is also an indication for operation. Profuse sweating should be noted, while vomiting, anorexia, and accelerated pulse rate may help to elucidate the case. Where the sinus has been exposed but not operated on, and aspiration shows that the lower portion is beginning to disintegrate, one is certainly justified in immediately ligating the vein. It is indicated even more if septic symptoms of even a minor degree are present, though no emboli have as yet entered the circulation. Another indication for ligating after exposing the sinus is the presence to the eye of the movement of respiration transmitted to the sinus, the dangers of embolism of air under these conditions, and the implied presence of a thrombus entering into the torcular, warranting the immediate ligation of the vein in the neck before the sinus is opened. This must be rare, however, as he has never seen a case in which this phenomenon was well marked. Infiltration of the soft tissues is a valuable sign, indicating phlebitis and thrombosis of the internal jugular vein, etc. In the third group of cases where the sinus has been opened and a large thrombus extending down into the jugular with coexisting purulent disintegration is seen, not before recognized, and it is not practicable and possible to remove the putrid mass without dislodging dangerous particles, the indications are perfectly clear to ligate the vein in order to prevent disintegration of septic matter. Another indication is the presence of a large firm thrombus, filling the sinus and extending well down into the vein, even if no septic or disintegrating changes be present. It has seemed advisable to Oppenheimer from his observation in cases of sinus phlebitis, to ligate the vein whenever local symptoms indicating its involvement were present. When there was sepsis, and especially irregular temperature and rigors, and when, after the mastoid has been opened, the presence of pus is evident in the vessel.

26. **Chorda Venerea.**—Peterkin considers this condition due to a local gonorrheal diseased area inaccessibly situated, and he would treat it by rest, if possible, prevention of erections, cleanliness, thorough flushing, a regulated diet, keeping clear of excitants and stimulants. In severe cases a fluid diet is needed, instructing the patient to sleep on a hard mattress with light covering and not to rest on the back, to avoid sexual excitement, emptying the bladder at least once during the night, the use of sandalwood oil and local baths to the part, etc., keeping the bowels free and avoiding wet feet. He would also use hot bactericidal, solutions, but speaks particularly of the value of massage of the prostate and seminal vesicles in acute gonorrhea as a valuable method in these cases. These relieve the desire for sexual excitement, remove abnormal stimulus and relieve congestion. He gives directions as to the methods of conducting massage by distending the bladder with water, pushing it down and massaging or stripping through the rectum until the prostate and seminal vesicles are emptied of their contents. Once or twice a week is usually sufficient. He thinks at the same time antiseptic injections to cleanse the bladder and urethra should be employed.

27. **Reflex Urethritic Eruptions.**—Two conditions especially noticed by Ravogli are herpes, which he finds, at least in the relapsing cases, to be generally associated with posterior urethritis, and pruritus of the anus, prostate and scrotum, which he found to largely depend on prostatic congestion. In the former disease he would treat the cause, using only local treatment for the herpes, usually washing with soap and water and using absorbent powders for drying. For pruritus he would advise massage of the prostate to relieve the condition of chronic pruritus, and the local use of ichthyol. When the excoriations have healed up and the eczema is improved, employ oxid of zinc ointment, etc. In the case of stricture he would use the sound freely, applying it every two or three weeks and then once a month until no more mucus comes out after its application.

28. **Eye Diseases.**—Marshall calls attention to the value in certain diseases of the eye of warm medicated sprays. They are indicated, he thinks, in almost all the diseases of the conjunctiva, such as acute catarrhal, chronic, epidemic, gonorrheal, trachomatous and phlyctenular conjunctivitis; in corneal diseases like ulcer, infiltration and interstitial keratitis and in iritis.

33 *The Islands of Langerhans in Congenital Syphilitic Pancreatitis. Richard M. Pearce.
34 *Some Experiments with Radium on Bacteria. Frederick Van Beuren, Jr., and Hans Zinsser.

29. **Typhoid Fever and Tuberculosis.**—Osler points out that these diseases may be concurrent. He thinks enteric fever is rarely mistaken for tuberculosis, but that much more frequently tuberculosis is mistaken for typhoid, and he gives illustrative cases where this mistake is most possible. In rare cases pulmonary consumption follows typhoid, but he does not think that the facts warrant the statement often made that typhoid convalescents are especially liable to tuberculosis. He believes that many of these cases are tuberculous from the outset.

30.—See abstract in The Journal, xli, p. 1105.

31. **Talma's Operation.**—Allyn reviews the statistics of this operation, including a list of 125 cases, 38 of which died within thirty days after the operation; 35 were not improved, and 51 were improved. About 60 per cent. altogether were not improved. He thinks, however, that a better selection of cases will reduce the mortality and increase the number of cures. In several cases where cure was finally obtained repeated tappings were necessary after the operation and the collateral circulation was only established after months. Certain contraindications, such as feebleness of the heart with chronic nephritis, nervousness, restlessness, etc., are also noted. He believes that in suitable cases the operation deserves a trial. He reports a case which was unsuccessful.

33. **Islands of Langerhans.**—Pearce briefly reviews the literature of the subject and gives the result of certain studies of the development and pathology of these bodies in the embryo. He finds that in the pancreas of the third month the islands are still connected with the acini by solid processes of cells. The proportion of connective tissue is very large, as the rapid glandular growth does not occur until the fifth or sixth months. Any disease of the pancreas occurring at this time would influence the development of the organ, and the evidence of this faulty development would be present at any subsequent stage. Syphilis of the pancreas has been observed as early as the fifth month, and it seems justifiable to conclude that syphilitic infection occurs earlier, at the third or fourth months, when the islands are still connected with the gland tubules, and that the newly-formed connective tissue causes atrophy of the gland, but spares the more resistant islands, as his studies show.

34. **Radium.**—Van Beuren and Zinsser have experimented with radium on bacterial growths, generally with negative results; only in one case, that being dubious, was there an apparent effect. The length of time employed, however, was shorter than that of Pfeiffer and Friedberger's experiments, and only one of the experiments was made in the dark chamber. The interposition of glass between the active substance and the matter to be acted on is also to be considered in estimating their experiments. They think that on the whole their researches point to the conclusion that we can not expect very much bactericidal action from radium.

*December 15.*

41 *A Plea for Child-bearing Women. William E. Ground.
42 Modern Renal Surgery. J. E. Moore.
43 *Some Complications of Strangulated Hernia, with Cases. Arthur T. Mann.

37. **Appendicitis.**—Conley advocates the medical treatment of acute appendicitis. He would himself, if called early, give a saline cathartic, but if vomiting is persistent and pain intense he would use ¼ to ½ grain of morphin hypodermically; then follow with a saline. Give as little opium after this as possible and apply the ice bag. As soon as the diagnosis is made insist on absolutely no food being taken by the mouth. If the stomach has not been thoroughly emptied by vomiting use lavage; otherwise he does not advise it. If the bowels are distended with gas and uncomfortable give 8 or 10 drops of turpentine. If the patient insists on taking something, give small doses of tincture of nux vomica or salol or salicylate of sodium. On the third or fourth day he would begin the rectal feeding, using predigested food or simply pure milk with normal salt solution. If the temperature drops to normal with no sign of abscess for two or three days, begin to give milk in small quantities. If an abscess forms, open and drain it. Later in any case if the patient does not recover or has much trouble with recurring attacks have him go to a hospital for operation.

41. **A Plea for Childbearing Women.**—Ground's paper emphasizes the need and greater attention to woman during pregnancy as to her general physical condition, and the accidents that are liable to occur and the percentage of narrowed pelves which seems to be nearly that of 13 or 14 per cent. In the Johns Hopkins Hospital two separate series showed almost identical figures of about 13.1 per cent. Others have given still higher figures. It is a matter that certainly needs the attention of the practitioner. The pregnant woman is subject to all of the diseases that others are liable to with added risk. Typhoid fever is a dangerous complication, causing fetal mortality in about 70 per cent. of cases. The same may be practically said of pneumonia, influenza, scarlet fever, measles, smallpox, etc. Chronic conditions of the heart, lungs and kidneys are badly influenced by pregnancy. Valvular disease of the heart is a very serious complication, especially with failing compensation. Tuberculosis, while it may apparently cause temporary improvement, is a very serious matter to the pregnant woman. There are also pathologic conditions peculiar to the state, such as kidney involvement, which is not by any means too carefully looked for. Slight hemorrhages after the beginning of pregnancy are too often neglected, though they may indicate tubal pregnancy, placenta previa or miscarriage. It is only by timely attention to these complications that safety can be obtained. The position in presentation should be looked after at the seventh month and every two weeks thereafter until the termination of the term, and the possibilities of dystocia should be borne in mind. As regards labor, he speaks of the necessity of absolute asepsis so far as possible. While his talk is elementary he thinks it nevertheless called for. Postpuerperal examination is a feature that is very commonly neglected. An investigation of gynecologic cases show the frequency with which women date their illness from pregnancy and parturition, and all these things mean something. After the immediate repair of the perineal laceration it is necessary to observe the patient for a month or two. There should be an examination four to six weeks after delivery to ascertain if the pelvic floor has sustained injury, if there is any tendency to retrodisplacement, etc., to observe the condition of the cervix and to estimate the process of involution. As regards retrodisplacements, Ground says that much can be done by not allowing the woman to lie on her back during the puerperium, and on every other day during the next three or four weeks having her take up the knee-chest posture and apply ichthyol and glycerin tampons, also not allowing her to hang heavy skirts from her waist. Postpuerperal retroversion can be prevented by compelling the woman to lie on her side after the first forty-eight hours.

43. **Strangulated Hernia.**—Mann notes complications and illustrates them by cases such, for example, as reposition of strangulated hernia *en masse* without attention to whether the strangulation at the neck of the sac still continues. The case here reported shows that lack of pain and localized tenderness is no absolute security. When there is no surgeon at hand taxis may be applied for a longer time, and it may be used with care under anesthesia. But if fecal vomiting and the duration of the strangulation indicates the death of the bowel, further delay is dangerous. The physician, however unwilling he may be, will then do well to operate if he can get the proper assistance.

### *Medical Fortnighty, St. Louis.*

*December 10.*

44 *The Life Insurance Question with Special Reference to Cardiac Lesions. O. E. Lademann.
45 *Spinal Injuries. N. B. Carson.

44. **Heart Disease and Life Insurance.**—Lademann holds that individuals with a slight defect in the mitral segments, which he calls favorable mitral insufficiencies, who lead a quiet life with light work, such as office work, whose habits are good, are but little more risky for life insurance than healthy individuals in the majority of cases. In the majority of cases such patients when told of their condition will live a life compatible with Nature's efforts to overcome the defect, and it will not be materially shortened by their infirmity.

45. **Spinal Injuries.**—Carson reviews the various forms of spinal injuries, dislocation, trauma to the cord itself, etc., and favors prompt operation in these cases. He has had the opportunity of examining Stewart's case of resection of the cord on two occasions, and is more than ever convinced that if he were called on to operate in a case of crushed cord, he would certainly resect and attempt approximation of the divided ends. He reports a case of dislocation which he reduced by suspension. The patient was totally paralyzed from the waist down and the eleventh vertebra projected beyond the one above so that he could bury three fingers under the projection. The patient ultimately completely recovered. In future cases, however, he would operate instead of using suspension, as his later experience teaches him that laminectomy is less dangerous.

46 Tuberculosis of the Brain and Its Meninges. E. G. Wood.
47 *A Brief Anthropological Study in Color. Q. W. Hunter.
48 The Card and Envelope System of Records. A. L. Benedict.

47. **Color.**—Hunter discusses the cause of color variations in the human race which seems to be independent of the anthropological stock. The Arabs and other non-Ethiopians in Africa are often as black as the natives. Native Africans may vary in color from a yellow-brown to a jet black, even in the same districts in different tribes. Another point is why the color of the offspring of the darker races is lighter at birth than later in life, and he notices varying statements in this regard. He believes that the offspring of full-blooded negro parents is a creamy yellow when born, gradually becoming darker, reaching the maximum or natural standard of color from six months to two years after birth. The offspring of a white or light mulatto mother and a full-blooded father will almost invariably be black or extremely dark, while full-blooded negresses have frequently given birth to light yellow offspring, the fathers being white. It is as difficult to explain the variations in color in the different races as it is to explain other peculiar racial characteristics, such as the almond-shaped eyes of the Mongolian, the high cheek bones of the Indian and the flat nose and kinky hair of the negro.

50 *Glossary of the Aphasias, Asymbolias and Alexias, with Comments. Charles H. Hughes.
51 *Mixoscopic Adolescent Survivals in Art, Literature and Pseudo-ethics. (To be continued.) James G. Kiernan.
52 *Note on Automatic Retrospective Slumber. Charles H. Hughes.
53 Out-door Sports for the Insane. J. T. W. Rowe.
54 *Outlines of Psychiatry in Clinical Lectures. (To be continued.) C. Wernicke.

49. ***Responsibility and Crime.***—Wherry's article is a plea for the recognition of partial responsibility of the insane. He insists that a large proportion of them are more or less responsible for their acts. To make them irresponsible there should be established a direct connection between the crime and the insanity. He says let the physician determine whether or not insanity is present, and then let the jury decide whether the prisoner is responsible or irresponsible by weighing all the facts and decide whether or not the crime is the direct sequence of the insanity. This, he thinks, would give better results than the methods now in vogue.

50. ***Aphasias.***—Hughes' article is a definition and discussion of the various forms of disturbances of speech and other methods of communication. It seems to cover the ground quite thoroughly, and is illustrated with schematic diagrams showing the presumed routes of the different forms of aphasic disturbances.

51. **Myxoscopic *Adolescent* Survivals.**—Kiernan's article is to be continued.

52. **Automatic Retrospective Slumber.**—What is understood by this title is explained by Hughes as a condition in which some extremely neurasthenic persons suffer from having the facts and actions of the day pass through the mind after sleep sets in, the mental ground of the preceding waking state being gone over again by the mind in a dream. For a long time these cases escaped his attention, he says, as he regarded them as only ordinary dreaming, but they differ from ordinary dreaming in that they are a repetition of the acts of the preceding waking period. The condition, he says, is plainly a brain tire symptom, similar in causation to the autopsychorhythmia previously described by him.

54. **Delirium Tremens.**—Wernicke's lecture covers this entire subject.

58 *Nature's Immunization of the Race Against Alcoholism—A Review and Criticism of Dr. G. Archdall Reid's Work on Alcoholism. Winfield S. Hall.
59 The Treatment of Inebriates. A. M. Roseburgh.

56. **Sea Voyages for Inebriates.**—Westcott points out the advantages and disadvantages of sea voyages for curable cases of inebriety. For the confirmed sot they are useless, and he thinks that excepting under favorable circumstances they are not advisable even for other cases. It is only where the patient will allow himself to be thoroughly under control and be absolutely restricted from all alcoholics that they will be of value. Under such circumstances there is no doubt that he might derive considerable benefit from the fresh outdoor life and change of surroundings of a sea voyage.

58. **Racial Immunity Against Alcohol.**—Hall accepts much of Archdall Reid's theory that the race becomes more or less immune or free from the alcohol appetite by natural selection, but thinks that his theory of the method is too pessimistic, and that much can be done by the proper care by the state of the children of inebriates.

64 Action Taken by the Department of Health on the Report of a Case of Smallpox. A. Blauvelt.
65 *Report of Committee of the Laboratory Section of the American Public Health Association on Bacillus Tuberculosis in Man and Animals. Mazyck P. Ravenel.
66 The Development of American Bacteriology. H. L. Russell.

61. **Tetanus and Vaccine Virus.**—Huddleston has experimentally examined to find whether calves used in vaccine laboratories are likely to be infected with tetanus germs. He concludes that the feces of calves fed on hay may contain the tetanus germs. They do not appear in the glycerinated virus. If any form of vaccine virus, either dry points or tubes of glycerinated virus, is infected with tetanus it may convey it. Small amounts of infection easily fail of demonstration, both by animal and by cultural tests. If the tetanus germs are applied in quantity to the inoculated areas of a calf at any time during the period of vaccine production, the tetanus may be present in the vaccine virus. Inoculation by scarification is a possible method of inducing tetanus in susceptible animals. He holds that it is probable that precaution against the issue of infected vaccine virus consists less in tests of the virus than in the care taken during the production, and especially in the cleanliness of the methods in use in the stable and laboratory.

65. **The Tubercle Bacillus in Man and Animals.**—This report is signed by de Schweinitz and Moore, and says that in summing up the available evidence there is strong ground for

believing in the genetic unity as well as the intertransmissibility of the human and bovine races of the tubercle bacillus. The committee considers that it has been positively proven that a certain proportion of persons, chiefly young children, meet their death through infection with the bovine tubercle bacillus, but the extent of this danger is not ascertainable with present knowledge.

74 *An Operation for Permanent and Quick Cure of Hemorrhoids. Almost Bloodless and Painless. John C. McAfee.
75 The Treatment of Gonorrhea. S. D. Warnock.

74. **Hemorrhoids.**—McAfee operates for hemorrhoids by divulsing the sphincter, using a clamp devised by Dr. Earle of Baltimore, to whom priority of the operation belongs, applied to the base of the pile in its linear axis at junction of normal mucous membrane, and then locked. Then using a double-thread catgut suture (Lee's No. 2) he sews under the clamp at the muco-cutaneous junction, catching the two distal ends of the thread in a forceps. After the needle is drawn through under the pile clamp, one of the threads on the needle side is cut off to facilitate tying. Then, cutting off the pile above the clamp a continuous suture is carried round and round the clamp, proceeding toward the upper end of the pile tumor. When the upper end is reached it is tied, the clamp withdrawn, the suture tightened and the lower end tied. This procedure is then carried out with each pile tumor till all are removed. He has performed this operation in 25 cases without any complications or trouble. The loss of blood is practically *nil* and the approximation of the cut edges is perfect and there is no tissue constriction. Anodynes are often not needed after the operation. A patient can return home in a week, and usually returns to work at the end of ten days.

81 Two Unusual Obstetrical Cases. W. S. A. Castles.

77. **Experimental Medicine.**—Krauss' article is an exposition of the conditions of immunity and contagion according to the Ehrlich theories.

78. **Cesarean Section.**—Farris holds that the life of the infant, under certain conditions, justifies cesarean section, which has as low a mortality as easy ovariotomy. Classical cesarean section is less mutilating than Porro's operation, and with the patient in good condition is the elective method. The Porro cesarean has about the same mortality as hysterectomy for fibroids, and it should be performed when the patient demands it or when infection or neoplasm makes it necessary. The practitioner should be prepared in the case of a multipara with a history of one or more dead children to perform the operation if necessary. If he does not possess the necessary surgical training he should call in surgical assistance.

18. **Mental Disorders Associated with Decay.**—Savage holds that senility is only relative and that premature senility gives the same results that the normal does; that environment has much to do with it. A man might retain the possession of his faculties to a good old age under quiet country life who would break down much earlier under the stimulus and surroundings of the city. He points out the characteristics of senile breakdown, more especially the defects of memory for recent events, which distinguishes the condition from the dementia of paresis where memory for recent events is generally retained. He holds, however, that paresis may occur in old age, though it is exceptional. There is also a loss of control as evidenced by maniacal outbreaks and in the lack of moral inhibitions. Special attention should be given to the characteristic cases of senile melancholia of the hypochondriacal type frequently associated with ideas of intestinal obstruction. There may be melancholia without melancholy, that is, the patient may not be actually depressed. A visible sign is the monotonous habit of repeating things and many of the patients who pass into senile chronic melancholia really do not suffer. Visual hallucinations are not uncommon and may be present with comparatively little general derangement.

21. **Gastric Cancer.**—Moynihan reviews the operations and the statistics. The questions he says that are in urgent need of settlement are: 1. Will palliative operation on the stomach prolong life? 2. Will it make the remnant of life more tolerable and the patient feel that the ordeal of the operation is justified in the greater comfort that he has obtained? 3. Will resection give reasonable promise of cure? 4. Will it not, if followed by recurrence, give increased length of days and better health? Kronlein's statistics are quoted and his conclusions stated, namely, that carcinoma of the stomach without operation is usually fatal within a year; that gastro-enterostomy prolongs the life of the patient for about three months on an average and that gastrectomy, so far as it is followed by recurrence, prolongs the life on an average fourteen months. Mikulicz' statistics are also given and compared. The results are almost the same as those of Kronlein, though the number was considerably greater. Moynihan says it must be admitted that we rarely obtain cases early enough to be hopeful and until more accurate methods of diagnosis are established, it is absolutely imperative that we should have recourse to exploratory laparotomy. To better our results we must explore not to confirm, but to make a diagnosis. While gastro-enterostomy has been spoken of unfavorably, excepting where there is pyloric obstruction, by Kronlein, von Mikulicz and others, Moynihan says there is no doubt it is occasionally productive of remarkable benefit, even when the growth does not actually obstruct by its blocking of the passage of food. In the majority of cases, however, little or no benefit results. If after exploration a growth is found obstructing the pylorus or narrowing the stomach and causing an hourglass condition, or if food stasis is present gastro-enterostomy will give very decided relief, but if the growth is confined to one or other of the curvatures without stenosis or stasis, this operation will not prolong life or make it more comfortable. The operation of gastrectomy in the hands of von Mikulicz, Carle and Fantino has given less mortality than gastro-enterostomy. It prolongs life more and there is a greater degree of comfort to the patient. He is relieved by the removal of a foul ulcerating growth and while, in the majority of cases, the growth will recur either locally or generally, the question arises whether it should not be performed deliberately as a palliative operation even when an early secondary deposit can be seen elsewhere. He sums up its advantages over gastro-enterostomy thus: In the most competent hands its mortality is even less; that prolongation of life for ten months longer than the period for gastro-enterostomy is the rule and that the comfort, general health and appetite are all emphatically better and the patient has a chance, though it may be a slim one, of complete recovery. Taking all these into consideration no doubt the operation of choice will be gastrectomy. If it is found on opening the abdomen that neither of these operations can be performed, some relief may be obtained by performing duodenostomy or jejunostomy. The scope of these operations is limited, but where prolongation of life for a few weeks is of great importance they are justified. The operations are simple, easily done, cause little or no shock and if it is necessary can be done under cocain anesthesia.

31. **Night Urination in Cardiovascular Affections.**—Retention of urine during the day and excessive urination during the night is not restricted alone to diabetes and sclerosis of the urinary apparatus, but is encountered also in affections involving the major or minor or the portal circulation. Péhu's clinical study of the subject indicates that the nycturia is due to insufficiency of the heart musculature which is unable to eliminate the fluids ingested during the day. They remain stored up in the tissues until the system relaxes during sleep and the arterial pressure rises. Elimination of the fluids then proceeds more rapidly. From this point of view nycturia may be regarded as an important sign of cardiac insufficiency outside of definite periods of "asystolie" (insufficient contraction of the left ventricle). Nycturia indicates reduction of the intake of fluids in order to lessen the task imposed on the heart.

32. **Diet in Albuminuria.**—Experience has convinced Daremberg that fish is an excellent article of diet in albuminuria, taken two or three times a week at noon. Two glasses of Vichy daily aid in maintaining the balance. After three or four weeks of this combination beef can be resumed with impunity, and finally an ordinary diet, abstaining only from alcohol, tomatoes and asparagus. His experience has been very favorable with this régime in cases of variable albuminuria—relic of a renal affection due to some infectious disease. Study of the relations between the albumin, the uric acid and the total acidity of the urine has shown that they all increase and decrease in parallel proportions in normal conditions. When the curves of the uric acid and total acidity are found to be at variance, the reappearance of albuminuria is imminent and should be guarded against by careful dieting.

34. **Tabes.**—Belugou remarks that tabes is extremely rare in women; all but 4 per cent. of his 1,960 patients were men. Syphilis was beyond question in 77 per cent. of the total number. The affection was rapid and fatal in 36 per cent.; 5 per cent. recovered, and in 59 per cent. the course was mild,

either arrested or with remissions. Antisyphilitic treatment coincided with marked improvement in 20 per cent., but improvement was equally marked in 23 per cent. who were not treated medicinally in any way. Antisyphilitic treatment should be tried in every case, he concludes, but it should be watched, as it is liable to aggravate the condition. Aggravation was noted among 44 per cent. of the 332 under mercurial treatment, and only in 24 per cent. of the 260 not treated. Mercury should, therefore, be abandoned if no benefit is apparent after a fair trial.

**45. Sugar Metabolism in Relation to Diabetes.**—Lépine has long sustained the theory that the pancreas, by means of its internal secretion, has a marked promoting influence on sugar destruction. Further research has shown, he states, that several glycolytic processes take place in the tissues, variable in their factors and mechanism. Also that there are a number of glycolytic ferments, and that the one in the blood is aërobic. Sugar metabolism is reduced in diabetes, and the glycolytic power of the arterial blood is likewise reduced in asphyxia, in concussion of the brain and after removal of the pancreas in dogs. The glycolytic power of the blood is enhanced by slightly increased alkalinity, and by stimulation of the pancreas. The latter was accomplished in his research by faradization of the nerves accompanying the pancreatico-duodenal artery, or by heating or massaging the organ. Simple ligature of the pancreatic duct also enhances the sugar-destroying power of the blood, and this effect is much more pronounced if accompanied by ingestion of an acid drink. This latter fact he attributes to the influence of the acidity of the stomach on the production of pancreatic juice, which fact Pavlov has established. Lépine refers to Cohnheim's announcements that pancreatic juice and muscle juice combined have a much more powerful sugar-destroying action than either alone. (See editorial on page 1480 of last volume.) He adds that this discovery was forecast in his own work published in 1899, in which he announced that pancreas tissue favored alcoholic fermentation, and further, that this favoring influence was much magnified by previous stimulation of the pancreas. In some of his experiments the fermentation was three times as active after the pancreas tissue had been previously stimulated, than in the control tests. These results were obtained the same even after the organ had been cooked. In later research on dogs he has shown that lymph from the thoracic duct of a dog promoted alcoholic fermentation much more when it was taken after preliminary excitation of the nerves of the pancreas. In conclusion he asserts that recent experiences have demonstrated that the *x*-rays have a marked influence in promoting sugar metabolism in the blood *in vitro* and in the living dog.

**46. Laryngeal Crepitation as Sign of Tuberculosis.**—Remouchamps confirms the great value of Cybulski's sign of crepitation heard with maximum intensity in the larynx as the examiner listens with his ear 5 to 10 cm. from the subject's slightly opened mouth. The sound resembles that of the scratching of a pen. This laryngeal crepitation persists during the entire course of the tuberculosis, and when very pronounced it can be heard by an experienced ear at a distance when the subject is speaking. This sign was noted regularly in about a hundred tuberculous patients, and was the means of establishing the diagnosis in a number of cases in which the tuberculosis was in the earliest stages. The specific crepitation differs from that noted in bronchitis, etc., by the absence of sonorous and sibilant râles and by its persistence.

**48. Kidney Organ Therapy.**—Renal opotherapy has been generally abandoned since its failure in Bright's disease, but Cassaet reports excellent results from its administration in a case of severe pyonephrosis consecutive to lithiasis. His patient ate raw kidneys every day for two weeks, and by the end of this time the extremely purulent urine had become limpid. This diet was continued without interruption for about six months, and the patient can now be considered completely cured. Arnozan of Bordeaux has also reported excellent results from ingestion of organic juices in cases of suppuration of the viscera.

**51. Adrenalin in Gynecology.**—Fénoménov has found that adrenalin affects different parts of the mucosa of the genitalia in a different manner, the same as its action is different on the mucosa of the nose, mouth or larynx. It does not seem to affect the mucosa of the vagina, but has a pronounced action on that of the uterus. He even found that ischemia was marked throughout the entire uterine mucosa when the adrenalin was applied to the cervix alone. He was able to curette the uterus with a minimum loss of blood after merely tamponing the cervix with gauze impregnated with a .2 per 1,000 solution of adrenalin. This difference in the response to adrenalin between the mucosa of the vagina and of the uterus could be noted on the same subject.

**54. "Gastrophor" for Gastro-intestinal Operations.**—Narath devised this instrument primarily for posterior retrocolic gastro-enterostomy, but finds it useful in all intestinal and gastric anastomoses. It dispenses with an assistant to hold the stomach, and prevents escape of any stomach contents into the abdominal cavity, even when the patient vomits, strains or coughs. It also prevents hemorrhage and facilitates operating as the field is less obscured, and the parts can be sutured as if spread out on a pincushion, while there is no danger of the button's falling into the stomach.

**56. Influence of Roentgen Rays on Epithelial Tissue.**—Perthes accidentally noticed that a wart on his hand vanished while he was working with the *x*-rays. He consequently applied this treatment in 18 cases of warts, finding that 16 vanished completely under the action of the rays. He has been equally successful in curing cases of ulcus rodens of the brow and recurring carcinomatous nodules in the breast. [In the discussion that followed this communication at the German Congress of Surgery, Lassar mentioned that the *x*-rays have a remarkable curative action on the professional dermatitis of physicians and chemists. Kümmel reported a case in which an ulcer developed after *x*-ray treatment and from the ulcer a carcinoma, compelling amputation of the limb.—Ed.]

**57. Perineal Prostatectomy.**—Voelcker reviews 11 cases of hypertrophied prostate in Czerny's service treated by perineal prostatectomy. One patient died soon after the intervention, and another from sepsis proceeding from injury of the rectum. He warns that in deciding on the mode of operation it must be agents of rabies were discovered in the hippocampus major in two of the animals, a dog and a rabbit.

96. **Immunization Against Tuberculosis.**—Friedmann announces that he has overcome the difficulties connected with attempts at immunization against tuberculosis with either human or bovine bacilli. He has succeeded in rendering guinea-pigs and other animals immune to virulent doses of these bacilli by previous injection of tubercle bacilli derived from a large turtle which had succumbed to spontaneous tuberculosis. Animals treated with cultures of the turtle bacilli respond with a local infiltration, but it soon heals, leaving scarcely a trace, and the animals remain in the best of health while they tolerate without reaction otherwise fatal doses of human and bovine infection. When killed after three months the guinea-pigs showed no traces of infection except scattered, occasional, minute nodules similar to those described by von Behring and others in their immunized animals. No bacilli could be found in any of them, and in time they would probably entirely retrogress. Turtles infected with turtle tuberculosis soon die with millions of bacilli in every section of any organ, but if previously treated with human or bovine tuberculosis cultures they are uninjured by infection with turtle tuberculosis, while all the controls die in a week or two. Experiments are now under way to immunize larger animals, cows, horses, sheep, pigs, asses and goats, by this preliminary treatment with the turtle stem culture. The guinea-pig, however, is considered the touchstone of the method. As it does not seem to be injured in any way by the turtle tubercle bacilli, Friedmann thinks that we are justified in assuming that they will not harm any mammal. On the other hand, as the susceptible guinea-pig is so readily and completely immunized against tuberculosis from other sources by this method, we must assume that the turtle bacilli possess high immunizing power. We thus have in the turtle stem culture a vaccine material which is not only harmless but confers high immunity.

101. **Causes of Acid-Fastness.**—Delbanco shows that the resistance of the tubercle bacillus to decolorization is due to the presence of a solid fat which protects it. This acid-fastness is shared by lycopodium spores, by cork cells and by certain other plant cells, and is due in each to the same cause, the presence of a fat more or less resembling tallow in its consistency. The presence of a non-solid fat does not confer this resisting power.

102. **Treatment of Pigmented Nevi with Hydrogen Dioxid.**—A 30 per cent. solution of hydrogen dioxid is applied twice daily to the nevus, a single drop on a glass rod. It is left to dry for fifteen minutes. The applications can be repeated several days in succession. They cause no appreciable pain. Cohn describes 3 cases thus treated at Unna's clinic. In each the nevus was very extensive, but under this treatment almost the entire extent of the nevus patches was cleared up in four weeks, and the few spots still left will undoubtedly subside under further applications at home, as the comparatively harmless substance can be safely entrusted to the mothers. One patient was a child of 5 with numerous dark moles over the entire trunk. In less than a week a large number of the nevi had disappeared completely under the applications of this 30 per cent. solution. Druggists have only recently succeeded in producing a concentration of this strength.

105. **Differentiating Staining Technic.**—Pappenheim describes some of the complex laws which govern the staining properties. Among others he notes that delicate differentiation of certain plasmatic substances is best done with what he calls an "adjective" staining with basic stains. On the other hand, differential nucleus staining is best accomplished with a "substantive" stain with basic stains, or an "adjective" staining with acid stains (alumhematoxylin).

115 Aristochin bei Bronchial-Asthma. K. Dresler.

108. **Ankylostomiasis.**—Zinn states that there are 17,161 cases of this affection known among the 181,730 miners in Germany. He reviews its history in other countries from the discovery of the parasite in 1838 to date, but apparently does not know of any American contributions to the subject.

109. **Phototherapy at Breslau.**—Krause reports that he treated 20 cases of erysipelas by keeping the patients in a room lighted only by a red light as tested by sensitized photographic plates. Comparison with 75 patients treated by other means showed that the average duration of the fever was a little shorter, 4.3 days with the red light and 6.2 without it, but in other respects the results were on the whole better without the red light. His experience with the electric reflector (Schuckert's Scheinwerfer) in 51 cases of various affections, including 5 of erysipelas, was more favorable, and he thinks the results observed warrant further trials of this measure. The benefits were most marked in rheumatism, lumbago, and neuralgia, the 28 patients in this class all asserting that they were much relieved during and immediately after the sittings. The effect was temporary at first and required several dozens of twice daily applications before complete cure.

110. **Therapeutic Application of Natural Gastric Juice.**—Pavlov's method of obtaining natural gastric juice from dogs has been successfully applied to pigs. The gastric juice thus derived has been tested at von Noorden's clinic, and in every case marked benefit was observed. Five cases are described in detail by Mayer out of a much larger experience. All the patients gained in weight during the five to seven weeks' course of treatment with this "dyspeptine." It not only substituted the inefficient or missing gastric juice but seemed to have also the power of healing the inflamed gastric mucosa and promoting the insufficient secretion. It was found especially useful in tuberculosis, restoring the appetite and slightly increasing the weight. In several cases of chlorosis and anemia accompanied by loss of appetite and vomiting, administration of the natural gastric juice just before meals cured these symptoms. The "dyspeptine" is not unpalatable, and the taste can be completely disguised by the addition of peppermint, lemon juice or beer. Stomach affections of any kind, acute or chronic, in which there is a deficiency of gastric juice indicate treatment with "dyspeptine" in doses ranging from 10 to 15 c.c. either just before or with the meals. As its action is both symptomatic and curative it can be regarded as a superior "stomachicum."

111. **Drug Treatment of Fissura Ani.**—Katzenstein deadens the sensibility of the nerve terminals in the fissure by applying cocain. He abolishes the spasmodic contraction with belladonna, and he disinfects the parts, to allow them to heal, with

a coating of ammonium sulpho-ichthyolate. His formula is .5 gm. extract belladonna, .05 gm. cocain hydrochlorate, and 6 gm. ammonium sulpho-ichthyolate. This mixture is warmed and applied on a piece of cotton twisted into a cord about the size of a knitting needle. It is inserted in the rectum along the wall opposite the fissure, and left until expelled. This application repeated twice a day will usually complete the cure of the fissure in a week or two at most.

**118. Clinical Diagnosis of Typhoid Fever.**—Gebauer thinks that it is usually possible to diagnose typhoid fever from the combination of temperature, pulse, roseola, spleen and early diazo reaction. The typhoid tongue and diarrhea are less characteristic but also useful when present, as also the palmoplantar sign, hypoleucocytosis, behavior of the urine and ileocecal phenomena. On the other hand, herpes labialis, icterus, sweats, speak against typhoid infection, as also coryza and conjunctivitis. His article is a comprehensive summary of what has been published on this subject in the last few years.

**121. Roentgen Treatment of Acne.**—Torök and Schein report 7 cases of acne vulgaris treated with the *x*-rays. The results indicate, they say, that this is the most effective and reliable of any method of treatment known to date. These cases were particularly encouraging as the affection had previously resisted every other known means of treatment. It is not invariably effectual as one of the 7 cases was not cured. The acne in this case was very extensive and the *x*-rays, instead of healing up the patches as usual after the second sitting, seemed to aggravate the affection. A diffuse inflammatory infiltration of the skin followed the second application with numerous subcutaneous nodules and superficial folliculitis. A minimal reaction to the rays is not always accompanied by the cure of the acne, but a moderate degree of Röntgen dermatitis should be aimed for. The disadvantages of the treatment are the pigmentation liable to follow in brunette subjects, the possible, slight atrophy of the skin and the exceptionally severe dermatitis reaction. The *x*-rays cause the lanugo hairs to drop out, and evidently check the secretion of sebum. They think that the beneficial action of the rays is due to this action on the sebaceous glands. Their parenchyma becomes more indurated and this explains the lasting benefit derived in nearly every case from Röntgen treatment.

**122. Orthodiagraphy of the Heart.**—Radioscopy of the heart gives very contradictory findings in clinical experience, and Hornung shows that these are due to inherent sources of error in the method itself. He gives cuts of hearts injected with plaster in the cadaver, showing that even extreme dilatation of the heart fails to cast a corresponding shadow, and that deductions based on radioscopy are eminently liable to be misleading. He comments on the implicit confidence of the general practitioner in the announcements from the university medical centers. He never troubles himself to verify the correctness of these announcements, and consequently errors take root and thrive, as in the case of orthodiagraphy (from the Greek term *orthos*, straight.

**123. Placenta Previa.**—The tampon and colpeurynter suffice for the majority of cases of placenta previa, but in case of a very rigid cervix and severe hemorrhage cesarean section may be necessary. Braun-Fernwald affirms further that when severe hemorrhage occurs once or more times during the last months of pregnancy the patient should be artificially delivered. He accomplishes this with a strip of iodoform gauze inserted past the internal os, packing the cervix and vagina tight with gauze. This procedure has always been successful, although it is better adapted for lateral than total placenta previa, as the gauze can be inserted higher up. As a last resort he advocates trying the method of clamping with forceps the uterine arteries as high up as possible. No mishap was observed from so doing in Henkel's 6 and Koblanck's 2 cases thus treated. If this fails, total extirpation by the vagina should follow, and without too long delay.

**125. Intestinal Occlusion.**—In one of the cases described the diagnosis in the case of an elderly woman wavered between carcinoma and simple coprostasis. A strong calomel purge resulted in the expulsion of a hard mass the size of a pigeon's egg, after which all symptoms subsided. The mass proved to be wax, and it was learned that the patient was in the habit of eating large quantities of unstrained honey. In 3 children the occlusion was due to cherry stones, or similar substances, which had accumulated in the rectum and had to be mechanically removed.

**126. Palmar Keratoma.**—Sack has been able to banish these horny tumors by bandaging them with freshly made, sweet cream cheese. The casein in this form has hygroscopic properties like glycerin. It is applied thick and covered with an impermeable dressing, left undisturbed for eight to twelve hours at a time. In a day or two the keratoma scales off to a soft, pink excrescence, which he then treats with a mixture of equal parts of borax and salicylic acid, 5 parts to 10 parts spirit. vin. and 80 parts glycerin.

**128. Diazo Reaction.**—The discredit into which this reaction has fallen in some quarters is ascribed by Ott to lack of proper precautions in the technic.. The reagents must be pure, undecomposed, the urine recently obtained and it must be known that the subject has taken no medicines for some time previously to the test. The proper tint must be obtained. When the test is positive the color is a cherry red or like that of raspberry juice, sometimes with a bluish tinge. The color fades more or less rapidly, but at latest in twenty-four hours, and this fading is an important characteristic of the true test. The color is most marked in the foam induced by shaking the fluid. He attributes great importance to positive findings of this test in the unfavorable prognosis of phthisis.

145 (No. 21.) Infantile Mortality and Cows' Diseases. O. Wyss (Zurich).—Kindersterblichkeit im ersten Lebensjahr und Blasenseuche der Milchtiere.

146 (No. 23). Ueber die Diagnostik der accidentellen Herzgeräusche im Kindesalter (heart sounds in children). Rheiner.
147 Cholelithiasis. Chologen-Behandlung Operation. Häberlin.

**130. Renal Tuberculosis.**—Suter reviews 19 cases of tuberculosis of the kidney treated by surgical intervention at Burckhardt's clinic. The mortality was 1/7, generally in cases with a tendency to a rapid course which the operation was powerless to arrest. The cure was complete and permanent in all the cases in which the affection was operated on before the tuberculous process had spread to other organs. When all the morbid parts could be removed the patient was cured. In 2 cases that came to necropsy the other kidney was found perfectly sound, as anticipated, although the bladder and prostate were involved as diagnosed before the operation. The first symptoms are vague; sometimes there is no pain at first, and the urine remains normal until after caseous degeneration of the nodules and communication is established between the cavities and the urinary passages. The bladder is usually assumed to be the seat of the lesion as the presence of pus in pathologic urine causes symptoms on the part of the bladder which are liable to mask those in the kidney. The orifice of the ureter and its vicinity become irritated early by the pathologic urine, and the subjective symptoms are of absolutely no value for the diagnosis of renal tuberculosis. Every case of spontaneous catarrh of the bladder in a subject between 20 and 40 should suggest the probability of tuberculosis of the kidney as the primary affection. The urinary findings correspond to the character of the tuberculous lesions and vary with their different phases. In case of a simple cavity the urine contains traces of albumin and little pus. In case the kidney is more diffusely affected, the proportion of pus and of albumin increases and blood cells may be found. If the kidney is very seriously affected, albumin to 1 or 2 per 1,000 may be found and considerable pus. Tube casts are seldom found and only in the severest cases. He noted them only once in the 19 cases operated on. Bacteriologic examination confirmed the diagnosis in every case. The kidney is by no means always sensitive to pressure, and pain may be referred to the sound mate. The diagnosis must be based principally on the cystoscopic aspect of the orifices of the ureters. In incipient cases they are still normal; in the more advanced, that side of the bladder shows the influence of the pathologic urine.

**131. Hydrotherapy in Sciatica.**—Cathomas comments on the rapid improvement obtained in a number of cases of sciatica after a few Scottish douches. Some of them were old, rebellious cases, but they responded surprisingly to various hydrotherapeutic measures. The results obtained confirm the assertions of Winternitz and others who attribute neuralgias to disturbances in the circulation in the nerves. Glatz in No. 15 also reports excellent results from hydrotherapy in sciatica and other neuralgias.

**132. Gelatin for Prevention of Post-Operative Hematoma.**—Tavel has noticed that post-operative local hemorrhage is most frequent during the summer and attributes this fact to the dilatation of the blood vessels from the heat. Corpulent subjects are most liable to it, while it is rare in children. He has been using for some time local applications of gelatin to insure coagulation of the blood and prevent after-hemorrhage. After the lowest suture has been made he irrigates the wound with his salt-soda solution, and then dabs it partly dry, after which he moistens it with gelatin, drizzling it along the entire extent of the wound from a fused tube, kept previously in a warm sublimate solution. the tip broken off just before using. The upper layers of the wound are then sutured, drizzling with gelatin from time to time. He has not had any post-operative bleeding since he has been following this technic except in operations on the bones; the gelatin is not able to suppress entirely all bleeding in these cases. Before using a new batch of gelatin he is careful to test it with cultures and inoculation of animals.

**134. Inexpensive Artificially Carbonated Baths.**—Cloetta fills a fountain syringe with a solution of $NaHSO_4$ and hangs it above the bathtub filled with water. The tube from the syringe terminates in a T-shaped glass tube with four openings along the branches. This glass tube is passed over the floor of the bathtub after the stopcock is turned, thus sprinkling a layer of the fluid on the floor of the tub. As soon as all the fluid in the syringe has thus been conveyed to the bottom of the bathtub, a corresponding amount of sodium bicarbonate is sprinkled on the surface of the water. As it dissolves only slowly in the water, it settles gradually to the bottom and at once a lively generation of carbonic dioxid results, the gas bubbling through the entire depth of the water, from the floor of the tub to the surface. The degree of carbonation can be controlled; the ingredients are inexpensive and the tub is not injured by them, while the carbonated bath thus produced is in many respects the exact counterpart of the natural carbonated waters.

## New Patents.

Patents of interest to physicians, etc., Dec. 1 and 8, 1903:

745311. Truss. Joel U. Adams, Cincinnati.
745784. Means for inspecting or testing eyes. John E. Chambers, Chicago.
745785. Warming device for use by invalids. Edward H. Coates, Macon, Ga.
745333. Serum and preparing same. Wm. P. Dunbar, Hamburg, German.
745856. Surgical sling. John F. Janisch, Kirksville, Mo.
745627. Instrument for testing eyes. Christian F. Kantlehner, Chelsea, Mich.
745913. Testing and fumigating apparatus. Milton Schanler, New York.
745685. Death-determining instrument. Jordan E. Storms, Jr., Yonkers, N. Y.
745468. Magnetic tachometer. Arthur P. Warner, Chicago, and C. H. Warner, Beloit, Wis.
746474. Suspensory bandage. Edwin R. Drake, De Land, Fla.
746502. Synthetic milk compound and producing same. Wm. A. Hall, Bellows Falls, Vt.
746336. Artificial leg. James Johnston, Jamaica Plain, Mass.
746338. Anatomical guard, boot or pad. Frederick W. Keen, Boston.
746380. Apparatus for administering anesthetics. Frank M Richardson and J. F. Field, Chicago.
746394. Optometer. Abraham J. Shellman, Grand Rapids, Mich.
746413. Disinfecting apparatus Leon Vandam, Uccle, Belgium.

# THE IMPORTANCE OF MEDICAL ORGANIZATION IN SECURING AND ENFORCING MEDICAL LAWS.*

T. J. HAPPEL, A.M., M.D.
TRENTON, TENN.

Repeated efforts to secure medical legislation in Tennessee had failed up to 1889. Our state society had time and again adopted resolutions commending medical legislation as a thing to be desired—an end to be attained—had gone so far as to approve the outlines of a medical act presented, and had appointed a committee to look after the matter at the next meeting of the legislature, even allowing the individual members to expend money (their own) if they so desired, to secure the passage of some act. I say permitting them to spend their own money if they saw fit, as no appropriation was ever made to aid the laudable purpose. Failure after failure was the result of such procedures. It must be remembered, however, that at that time (in the 80's) the Tennessee State Medical Society had a membership of less than 300, the larger percentage of those carried on its roll never being present at or participating in any of its meetings. With a profession in the state numbering 3,300, the state society could lay claim to from 8 to 10 per cent. of its physicians. It is not to be wondered at, then, that medical legislation was so hard to obtain in this state. What is true of Tennessee doubtless is true of most of the other commonwealths of our Union. So long as the profession took no interest in obtaining legislation nothing could be expected.

The first law passed in this state in 1889 was not what was wanted or needed, but was all that could be obtained, having become a law by one vote more than the constitutional majority demanded. The passage of that act was vigorously opposed by some members of our state society, they taking the position that to medical men belonged medical matters and that the politicians and legislators had no part or lot in such affairs. Yet when these opponents of medical legislation were confronted with the question of how to remedy the growing evils of all forms of quackery, no answer could be given by them. They took the position that each town, county or state should regulate its medical matters through the profession in the respective localities. Up to the passage of our first medical law no concert of action could be had on any medical matter. In state sanitation one faction opposed anything that another faction would suggest as right and proper to be done. In every city in the state there were as many factions in the regular profession as there were medical schools, plus one, namely, those who were not connected with any college, and then each other "ism" in medicine represented another dissenter from what was being done. So, then, in Memphis, with only one college, there were the college and anti-college factions, and in addition the eclectic and homeopathic set, though the two last named usually made common cause together; as at the time of the passage of the act of 1889, there were less than a hundred graduated eclectics and less than twenty graduated homeopaths in this state.

Nashville, boasting three white medical schools, had then always four factions, plus the one represented by the other two "isms." And so I might enumerate further. Each medical school was the best in its own estimation, and what one did the other did not; one favored chloroform as an anesthetic, the other ether; one advocated bleeding for puerperal convulsions, another gave chloral; one would press forward one of its own school for any medical position, and another would do all in its power to defeat the applicant and endeavor to supplant him with one bearing its colors. In each community the same condition of things existed. Not more than two physicians in any community were on social terms or often even on speaking terms, and this union of two arose from a community of interests, a common desire to down some other physician. It was a notorious fact, known not only to the medical profession of the state but to the laity also, that but few physicians in a given locality were willing to consult with each other, even in emergency cases. In reply to a call to see a patient, too often the answer was, "Dismiss Dr. A. and I will call and do what I can for you, but I do not speak to or recognize Dr. A. professionally," and Dr. B. was equally as ready to reply in like manner if asked to see a patient under the care of Dr. C. But I need go no further along this line. What was true of Tennessee was equally true of many if not most of the other states.

The first register made of the profession in this state when the act of 1889 was passed, which required every physician in the state who was engaged in the practice of medicine on the 4th day of April of that year to make proof of that fact, either by witnesses or by the presentation of his diploma, showed that of the nearly 3,300 physicians reported by the various county court clerks as complying with the act, 47 per cent. were non-graduates and 53 per cent. were graduates. Of the non-graduates many had never been inside of a medical college of any kind. If any had ever, prior to April 4, 1889, administered a dose of castor oil to a child or adult (though he were a member of his own family) and could prove the same by two reputable witnesses, he was permitted to qualify as a legal practitioner and such registration was reported to the secretary of the board of examiners, and under the law he was forced to accept the report as true, even though he knew the facts to be as above suggested. We could not go "behind the returns." A united profession had not demanded the passage of the act, and those who had, were compelled to be content with what could be gotten, and then to try to mold public opinion favorable to it.

---

* Read before the Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7, 1903.

In one of the counties of the state where a county medical society had been in active existence since 1882, it was not difficult to have at each succeeding county convention her nominees for the legislature instructed to support any medical legislation desired by the county society. The members of the medical profession in that county were not politicians in the sense of seeking office, or of neglecting their professional duties, but each one felt the full measure of the duties of a citizen resting on him to take part in his district and county convention, and did not hesitate to say that he favored this or that candidate. The physicians in that county were model citizens—men who thought about public matters and could readily give an answer to questions in regard to such matters, especially those pertaining to the affairs of their state, that might be propounded to them.

Other counties where no such organization existed, where personal rivalries and professional jealousies precluded the possibility of a medical organization, could do nothing. No united front could be presented by the physicians on any public question, and when Dr. A. ventured to call on his nominee for a promise in regard to medical legislation, he was met with the reply that Dr. B. had just made the opposite request, that he should oppose any such legislation, and that such being the case he could not bind himself to any special line of conduct in regard to these matters. When any medical question was up for discussion and a vote drew nigh he conveniently absented himself or voted in the negative. As county medical societies increased in numbers, medical legislation could be more and more easily attained.

In 1897 it became possible for us to get an amendment through both houses by good majorities requiring all, whether graduates or not, who desired to begin the practice of medicine to come before the board for examination. The same legislature passed a law distributing the unclaimed dead from our penitentiary and insane asylums between the medical colleges of the state. In the next legislature the medical students in the colleges in Nashville raised a sum of money and secured the services of attorneys (one of them being a member of the legislature) to have the amendment of 1897 repealed. These students from every quarter of the state appealed to their senators and representatives to vote for repeal of the act on the ground that a diploma obtained on three courses of lectures should be sufficient license on which to base a right to practice medicine. When a few members of the medical faculties in Nashville attempted to stay the current in favor of repeal, they were met with the threat that unless they ceased their efforts, which were beginning to avail, against the repeal, the "Stiff Bill" would be wiped off of the statute books. All ceased opposition, with the exception of a representative or two from one of the colleges, and left medical legislation to its fate. To these exceptions all honor is due. There was not enough of union or unity of purpose to enable and induce all to act together. The loaves and fishes of self-interest outweighed *the claims of the whole profession. As with individuals, so it seems to have been in medical schools.* The fear of individual loss causes many to do what they would not otherwise do. This plain statement of facts is not intended to be nor is it a reflection on the medical profession of Tennessee. No doubt under the same or similar circumstances in other states, there would have been the same results. There was no organization among the schools or medical profession at that time. Politicians knowing that condition to exist, availed themselves of professional jealousies to accomplish the emasculation of medical law. The result of this amendment of the medical restrictions in this state, caused the profession to realize the necessity of "getting together," and at the next meeting of our state society, which was held in April of that year in Nashville, the physician, who delivered the welcome address said with much emphasis that the time had come when every member of the legislature who had voted to virtually repeal all medical restrictions in the state should be remembered by the physicians in every county, and their return to the next legislature prevented so far as medical opposition could avail.

Medical organization received a fresh impetus in this *state from the stab it had received in what should have* been the house of its friends. *But in reviewing the action of the legislature of that year, a different course* could not reasonably have been expected. The students were organized from all parts of the state to secure the repeal of the "examining clause," and the profession of the state left the examining board alone to oppose such action—six men resisting 500, not one of the six being related by any ties to any member of the legislature, while many of the students were either sons or nephews.

Wherever the medical profession has presented any semblance of a united demand for any legislation, *it has been gotten not only in this state, but in all others of the* body politic. No man wields more influence in his own voting precinct than does the physician who lives and practices therein, if he be what everyone who claims to be a disciple of Æsculapius should be. As stated by Dr. McCormack in an address before the North Carolina State Medical Association, the physician should be the best man in every sense of the term in any community. He should be well educated, well dressed, of irreproachable morals—should be, to sum it all up, a man *"sans peur et sans reproche," "sans tâche."* I desire to add that he should be not only such a man as portrayed above, but he should be a good citizen. He should take an interest in public affairs, should have an opinion about public matters, and should not hesitate on proper occasions to give expression to those opinions. He should not obtrude himself or his opinions on others, but when called on he should be ready to give a reason for the faith that is in him. A physician who knows nothing outside of a medical book may be fit to live in a city, but we in the country do not want him. There must be in him a large element of common sense in addition to book erudition. As was said by Dr. I. N. Love in the *Medical Mirror:* "He should not begin life as a physician with the idea that he can not also be a citizen in the true sense of the term." Anyone can be, as the Latins expressed it, a *"homo,"* but not everyone a *"vir."* A physician must be more than a human being—he must be a manly man who takes part in all public matters and is not afraid to express an opinion about them when occasion demands. He must not carry a "chip on his shoulder," for some one will knock it off;

he must not attempt "to face both ways on his horse"; he can not do it. It has been truly said that you can fool some people all of the time and all of the people some of the time, but you can not fool all of the people all of the time. A physician should be a Christian gentleman, and if you want a type of such an one as a model study, take Nehemiah of the Old Testament. Be what he was and you will fill the full measure of your citizenship.

With these requirements met as to the personnel of the profession and county and state organizations, any legislation, as already stated, that is desired and that can be defended as just and equitable, as protecting not the profession of medicine alone, but as safeguarding the interests of the *"hoi polloi"* as well, can be secured. But one objects that this idea of obtaining medical legislation through organized medicine is abandoning an old landmark, is dabbling in politics, or as our "holier than thou" brethren are pleased to say, the "dirty pool of political scheming." The very reason that politics has in these latter days become dirty is due to the fact that the better element holds itself aloof and allows the government of most of our municipalities and too often the legislatures of our states to be dominated by the rabble.

Dr. Hawley, in a paper[1] read before the American Academy of Medicine at Saratoga, made the following correct statement about the relation of the physician to politics:

> In every community the physician is looked on as belonging to an educated, cultured and refined profession. He is naturally accorded a high position to make an impression on public opinion. The physician, by his preliminary and professional training, possesses a degree of mental vigor and refinement above the average citizen. Further, the physician, and especially the country physician, from the nature of his calling and environment is a close observer and generally a correct interpreter of his observations. Thrown continuously in contact with important and vital questions, and often on his own resources alone, he learns to observe carefully and quickly, to reason rapidly, and to act at once. He is a man who is obliged to depend on himself, to draw his own conclusions and to work out his own problems. His daily work and experience, therefore, tend to cultivate a keenness of insight, a power of discrimination and independence of judgment, which will enable him intelligently to grapple with the important questions which are vital to the interests of his state or his municipality.
>
> Further, the physician is better acquainted with men, and has a better knowledge of human nature than the average citizen, and, therefore, is in a position to understand thoroughly many of the requirements of the community. From technical knowledge and experience the physician is especially qualified to render valuable services to the community in matters relating to public health and sanitation, water supply, plumbing, drainage, sewerage, ventilation, schoolhouse construction, etc.

Another desideratum to be attained in connection with this subject of our organization is the lessening of the number of medical colleges run chiefly for individual profit; but as this subject was so ably handled by Dr. Frank Billings in his most excellent presidential address[2] before the American Medical Association at New Orleans, I will not consume your time in discussing it. In Tennessee we have seven white and five colored medical schools, besides one or two fraudulent ones, while our neighboring state of Kentucky, though not quite as well supplied, has enough and to spare. As the personal interest of the individual too often predominates over other interests, concert of action where so many schools exist—run in nearly all cases for the sake of making money—is a utopian ideal. Nashville and Louisville are each large enough for one school, and yet how many have each place?

Taking up the second branch of my subject, viz., the importance of medical organization in the *enforcing* of medical laws, I must be pardoned, should I make use of some ideas that I have already advanced in THE JOURNAL.[3] If it is difficult to procure medical legislation without medical organization, it is still more difficult to prevent the repeal of such laws and much more difficult to enforce them. Violators of the law will not oppose the existence of a statute—its presence on the statute books—unless it is enforced. So long as the law remains a dead letter it is not to be dreaded, but so soon as an effort is made to carry out its provisions, then it is resisted. In no state, perhaps, has a medical regulation act been passed which has not been attacked on grounds of unconstitutionality, and in most cases unsuccessfully. The highest judicial tribunals have almost invariably held such laws constitutional under the broad mantle of police supervision. When an effort to have such a law declared void has failed, the next step is to endeavor to influence the law makers to repeal, and, failing therein, to amend it in such way as to emasculate it, to render it powerless to accomplish that for which it was originally passed. The amendment is far easier to obtain than the repeal, and these amendments may be of such a nature as to appeal to the vanity of the legislators, such, for example, as exempting from the provision of the act graduates of state schools, and in this way render the act obnoxious to those who have seen fit to obtain a medical education outside of the confines of their own state. The plausible plea of encouraging home institutions and protecting their graduates to such an extent as to induce all to graduate at home, will have weight with many law makers, and on the floors of many law-making bodies the disinterested (?) member has been heard to declaim on the pride that one should take in a diploma issued by one of our great institutions of learning, the inside of none of which he has ever seen except as a mere passer through. These demands for amendment or repeal can be met successfully only as they were passed, by the efforts of a united profession. The same influences must be brought into action to prevent repeal or amendment as were used to secure the passage of these laws.

But when a law has been passed and its repeal or amendment has failed, the successful enforcement of it is perhaps the most difficult matter yet to meet. Many who have not complied with the requirements of the act are able to and do secure to defend them in its violation, some of the very men who voted to pass the law and even spoke for it originally. This I know to have occurred in our own state. All kinds of excuses are presented for failure to comply with the law—from ignorance of the existence of the law up to a refusal without excuse to comply with it. The numbers of physicians who belong to the lists of those neglecting and those defying is large and they, making common cause with traveling quacks and charlatans who furnished the money for the legal battles, present a menace to the successful enforcement of the medical laws.

Again, the profession is disposed to think that because the act gives the grand juries inquisitorial power over all violators of the law, and because the judge is required to give the act in charge, that everything will be done that can be done without further action on the part of the profession. Never did a more erroneous idea creep into and take possession of the minds of reasonable and reasoning beings. The judge and prosecuting attorney were elected by the votes of their constituents, of whom the violators of the medical act are integral parts, representing just so many votes. Instead of charging the act to the grand jury, it is overlooked and neglected, or if it is given in charge, it is done in such a way that that body soon learns that nothing is expected or wanted by the judge along that line; and the attorney-general, who is serving for a fixed salary, summons no witnesses. If, however, the county medical society, an organized body, having on its roll every reputable physician in the county, furnishes him with the names of witnesses in any case and says to him that they demand that the law be enforced, then it is done promptly. What Dr. A. as an individual could not secure, Dr. A. or Dr. B. as the accredited representative of the county medical society, easily succeeds in getting done. But to depend on a salaried prosecuting official to attend to the violators of the law, is to show a willingness to leave them as dead letters. He feels that a prosecution of such cases will make the defendant and all his friends enemies of himself, and his work is done in a half-hearted way. To successfully enforce the law, an attorney must be employed either by the examining board or by the county society. An attorney acting for the board, the state or the county society will take a deeper interest in his work than a salaried official will do. With him it will be a matter of pride to convict the offender, while the salaried official will proceed in a perfunctory manner to discharge his duty, not caring for results. The attorney representing the board or society will know too that the continuation of his employment will depend on the zeal displayed in and the success of his efforts. An attorney who wins no cases will soon be replaced by another.

[1] THE JOURNAL A. M. A., June 21, 1902, p. 1665.

[2] THE JOURNAL A. M. A., May 9, 1903.

[3] THE JOURNAL A. M. A., Nov. 16, 1901, p. 1301.

In this state it has not been difficult to secure convictions when we have proceeded as above, but a jury ordinarily assesses the lowest possible fine and if a number of indictments are not secured against the offender, but little is done to stop his illegal work. This is a serious trouble where advertisers who travel from county to county are concerned. They reap a rich harvest from their unsuspecting victims, and when arrested plead guilty before some magistrate, begging the leniency of the court, getting as small a fine as possible. This they pay, and at once leave for newer pastures further from the oversight of the board, where no organized medical society exists, and ply their trade rapidly until reported again. A new attorney has then to be secured before anything can be done, and in the interim they gather in the coin and are ready to pay the new fine and move. This can be kept up indefinitely when the medical profession lacks organization, but when they are organized they soon force the quack to leave the state; but when the county medical society lacks backbone enough to report such cases and to aid in their prosecution by securing an attorney willing and ready to act, no matter how zealous the board of examiners is, no prompt enforcement of the medical law can be secured. There must be the most hearty co-operation on the part of the board of examiners and the county and state organization. With such concert of action, the possibility of the medical profession, both in securing and in enforcing reasonable legislation, can not be fairly and fully estimated. In proportion as the individual failed, organized medicine will succeed.

Going a few steps farther than I intended as the scope of this paper, I may be permitted to add that when the American Medical Association has drawn into its folds the members of the medical profession who should legally belong to it, there will be no trouble to secure a department of public health, with a medical officer at its head as a member of the President's cabinet, and reciprocity in medical licensure will no longer be an idle dream. Uniform medical laws can be passed in all the states of the Union, with only such variations as may be demanded by the constitutions or laws of the different states; and then all the requirements can be made so nearly alike for license to practice medicine and the examinations on such an equal basis that a license issued in one state will be accepted in another without question.

# SOURCES OF PLAGUE.*

W. J. CALVERT, M.D.
Department of Clinical Medicine, Missouri State University.
COLUMBIA, MO.

This subject involves a discussion of the early and present pandemics, cardinal features of the viability and dissemination of *Bacillus pestis* and the transmission of plague.

## HISTORICAL SKETCH.

While indefinite statements regarding plague are found in the earliest writings, no definite knowledge of this disease has been found until the writings of Rufus of Ephesus regarding plague in Egypt in the second century B. C. At this time the disease was present in lower Egypt, spread along the coast of the Mediterranean and existed as a pandemic for an unknown period. Numerous detailed accounts give positive data that this pandemic was the same disease as that now known as bubonic plague. During this period war, drought and famines were prevalent throughout the world. During the centuries following this pandemic, numerous references to plagues are found, but each is too indefinite to warrant a diagnostication of bubonic plague.

In the Justinian age, beginning about 540 A. D., plague reappeared in pandemic form. Starting in lower Egypt, especially Pelusium, the disease spread along the shores of the Mediterranean to Asia Minor and Europe. In this pandemic plague existed in a given locality one, two or three years, disappeared to probably return at a later time. The nature of the disease was similar in most respects to what we now know as plague. This pandemic continued for fifty or sixty years, and in all probability gradually died out. In this age wars, droughts and famines were also prevalent. During the middle ages numerous references to plagues are found, but again they are too indefinite to enable us to distinguish the nature of the disease. It is most probable that plague played an important rôle in all these epidemics.

In the fourteenth century plague again reappeared in pandemic form throughout the civilized world. This time the disease began in western Asia, traveled to Asia Minor, thence to Egypt, Europe and Russia. During this pandemic some places were infected only a few months, others for several years, while in others epidemics continued for one or two years, after which the disease disappeared to again reappear after a longer or shorter time. Again, war, droughts and famine were prevalent. Several centers, so to speak, became temporary distributing points for the disease. Of these, Egypt in Africa, Turkey in Europe, and Syria in Asia were the most important. Again in these countries the disease remained more or less active for three centuries, giving rise, from time to time, to epidemics in neighboring countries. As the centuries wore on, the number of epidemics gradually diminished until 1841, when the last epidemic of plague occurred in Constantinople. In recent times Arabia was visited by epidemics in 1853, 1874 and 1879, Tripoli in 1874, Persia in 1863 to 1878, Messapotamia from 1866 to 1876, and in Astrakhan in 1878.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

From 1879 until 1894 the world was practically free from plague, but in the latter year an increased death rate among the Chinese at Hong Kong was observed, an investigation of which revealed the presence of bubonic plague, not only in Hong Kong, but also in Canton, where it probably came from Lientschau and Pakhoi. Since then the disease has spread to India, Japan, the Philippines, numerous ports along the route to Europe, South America, South Africa, Portugal, England, San Francisco, Mexico and many other localities. We are, then, in the midst of another pandemic of bubonic plague. Thus plague has spread over the world in at least four pandemics. First, in the second century, second in the Justinian age, the third in the fourteenth, and the fourth in the nineteenth century.

A brief summary of the observations on these pandemics reveals the following:

*As to Origin.*—No mention is made regarding the origin of the pandemic in the second century B. C. In that of the Justinian age the disease began in lower Egypt to spread over the then known world. During this pandemic new infected centers of plague were established in western Asia, where the third pandemic in the fourteenth century arose. During the third pandemic new centers were established in southern China to give rise to the present pandemic in the neighborhood of Canton. Thus plague has shifted its home from Egypt to western Asia, and later to southeast China, remaining throughout the centuries in tropical and subtropical climates.

*As to Infected Centers.*—Probably owing to more accurate detailed records, plague has in each of the latter pandemics formed new temporary centers from which the disease spread over the neighboring countries. Of these, Constantinople in the fourteenth century, and Hong Kong and Bombay in the present pandemic are notable instances. In these centers the disease may occur from year to year or at irregular intervals in epidemic form, or its presence may be shown by occasional cases.

*As to Routes Traveled.*—During each pandemic the disease has followed the great paths of commerce. In the second century B. C. it spread along the coast of the Mediterranean; in the Justinian age, along the same routes to Asia Minor, thence to Europe and western Asia; in the fourteenth century, from western Asia to Asia Minor, thence to Egypt, Europe and Russia, and in the nineteenth century from south China to Canton, to Hong Kong, thence throughout the world.

*As to Classes Affected.*—All races have been affected, especially the lower classes. Among the higher classes, living in the better districts of a city, the servants, as a rule, suffered. History abounds with instances of domestic and wild animals suffering from severe epidemics.

*As to Modes of Dissemination.*—Here records are liable to lead astray, for even now much mystery surrounds the dissemination of plague. It has been noted that clothing and articles of commerce have served to transport the disease, and the migration of rats, etc., has been observed.

*Historical Recapitulation.*—In each pandemic a new endemic home was established, first, in Egypt; second, in western Asia; third, in southeast China; temporary infected centers were established from which the disease spread in epidemic form; given localities were again and again infected; pandemics lasted from fifty to sixty years; in infected centers plague remained more or less active for several centuries, and the lower classes were mostly affected.

As the present pandemic first originated in Lientschau, then extended to Canton, from Canton to Hong Kong, thence to the civilized world, it is important to relate briefly the existing conditions in south China. The entire southern portion of China is thickly inhabited, with a large number of densely populated cities. Of these the most important, geographically and commercially, is Canton, which is located on the Pearl River about ninety miles northwest of Hong Kong, with which it is in intimate intercourse by water and land. It is a filthy, densely populated, poorly constructed city, consequently unhygienic conditions exist. Living under these conditions, the natives have a lowered resistance to infection of all kinds, consequently epidemic diseases are most prevalent. On account of the filth and customs of the people, rats and insects are abundant. Similar conditions exist in all Chinese cities.

## FEATURES OF THE BACILLUS.

The *Bacillus pestis*, discovered by Kitasato and Yersin in 1894, grows luxuriantly in all ordinary culture media, even under disadvantageous conditions. As our knowledge of this organism increases, its power to maintain life and virulence under unfavorable conditions becomes of more and more importance. It has been found that the organism lived nineteen days in the sunlight and twenty-three days in darkness, at ordinary room temperature; twenty-two days in a desiccator; eleven days in a thermostat; one hour in a temperature of 60 C., and fifteen minutes at 80 C. The German Commission found virulent organisms in sputum after ten days; Martini in sputum of a pneumonic case after seventy-six days; Abel in sterile water after twenty; Hankin in various cereals after thirteen; Jakote in buried plague cadavers after thirty, and in dried pulverized organisms of animals dead of plague after forty-eight. On dried paper kept in a thermostat, organisms have been recovered after forty-four days, and in direct sunlight, after from three to six hours. Under favorable conditions, as on culture media, the organism lives indefinitely. Its virulence, even in old cultures, is frequently as great as in young ones. The finding of bacilli which rapidly regained their virulence in cotton goods by Kitasato is one of the most important links in tracing plague from one country to another. When plague was discovered in Kobe, Japan, it was found that a large consignment of cotton goods had recently been received from Bombay. Two hundred tubes were inoculated with portions of these goods, from one of which a virulent plague culture was obtained. Several dead rats were also found in bales of cotton. It is more than probable that by this means plague was introduced into Japan.

These facts demonstrate the resistance of *Bacillus pestis* to dryness and a moderate degree of heat for an undetermined period, and suffice to explain the origin of succeeding annual epidemics in a given locality, and to show one route and means of carrying the disease from one country to another.

The susceptibility of rats, mice, domestic animals, flies, flees, ants, etc., serves to preserve the life and virulence of the bacilli, and to spread them in accessible places. The migration of rats, etc., may serve to carry infection to neighboring districts.

As bacilli have been found in the blood during a period of forty-five days, and in sputum for seventy-six days, convalescent patients may be a means for carrying the disease from one district to another, or even to distant lands.

Returning to the origin of the present pandemic, it is more than probable that during the pandemic of the fourteenth century, or the numerous epidemics of the following three centuries, south China was visited by plague when a new endemic home was established. After an indefinite time the disease increased, extending by ordinary routes of travel, in merchandise, etc., from outlying districts to Canton, where, favored by the filthy, crowded condition of the city, an extensive epidemic immediately developed. Here merchandise of all kinds comes in intimate contact with infectious material, and undoubtedly harbors more or less bacilli. Hong Kong, the port of Canton, undoubtedly received its infection from Canton by means of merchandise, individuals who might have contracted the disease in Canton and developed it in Hong Kong, or possibly by means of rats boarding steamers at Canton.

Hong Kong is one of the most important shipping centers in the Orient. Here practically all vessels plying in Oriental waters touch for coal, cargo and the transshipment of cargo, all of which are handled by Chinese coolies who live in the plague districts of the city. In addition to cargo, rats in large numbers often board the steamers to be transported to distant ports.

In the spring of 1894 plague spread from Canton to Hong Kong, thence to a number of coast towns in southern China, and later to many distant ports, or in other words, the disease followed the ordinary routes of travel.

In the present pandemic Canton and Hong Kong are the chief distributing centers for the world, thus history is repeating itself. Consequently we may anticipate the presence of plague in these cities for an indefinite period to give rise to epidemics of plague at irregular intervals in various portions of the world.

## TRANSMISSION OF PLAGUE.

Transmission of plague is best considered under the headings of *portals of entry*, direct and indirect transmission.

*Portals of Entry.*—On account of the absence of local reaction in the great percentage of cases much doubt exists as to the real portal of entry. This is made more prominent by the slight local reaction found in the small number of cases in which a primary sore is found. Here almost no change in the surrounding tissues are noted, frequently only a slight lymphangitis is observed, and usually the first lymphatic gland draining the infected area is the primary bubo. The absence of a slight local reaction about a primary sore leads one to think that a small wound in the skin might be infected without visible local reaction.

Experimentation on lower animals shows about the inoculated area an intense edema, more or less hemorrhage, and considerable infiltration, with the lymphatic glands draining this area enlarged, hyperemic, and often hemorrhagic. It must be remembered that in experimentation a very large number of bacilli must be inoculated. As in all of these experiments lymphatic glands draining the inoculated area are the first affected, it seems most reasonable to suppose that primary buboes in human beings indicate the region through which the infection was received. In the unshod Oriental races about 60 per cent. of primary buboes are femoral or inguinal, 25 per cent. axillary and the remaining cervical. These percentages fairly accurately represent the relative exposure of the several regions to infectious material. The relative frequency of primary buboes in children strengthens this supposition. Here the largest percentage is found in the cervical regions, next in the axillary and inguinal, and femoral least of all. It is well known that whenever possible a child will put everything into its mouth, and is inclined to play on the ground, where the hands are more liable to infection than the feet. As the larger percentage of cases are of the bubonic type, it seems most reasonable to suppose infection is received through superficial wounds in the skin and mucous membranes of the mouth and nose.

The apparent immunity of oil workers and those well clothed seems to favor the opinion that infection is most often received through the skin.

Wilms thinks the digestive tract is an important portal of entry, but numerous observers doubt its importance. In two epidemics I saw no evidence of infection through this tract. Experimentally primary mesenteric buboes have been observed.

Infection through the lungs undoubtedly occurs, especially in pneumonic cases. Deane considers the pulmonary tract the most important portal. If this were true, it would be as difficult to explain the absence of local pulmonary changes in the great percentage of cases as it is to account for the lack of local reaction in skin wounds. Again, it would be difficult to explain the distribution of primary buboes if the bacilli entered through the lungs.

Some evidence points to the sexual organs as a portal, but more observation is needed to establish this fact.

*Direct Transmission.*—Here the most important feature is the infected human body. As septicemia develops, all organs, secretions and excretions become infected. Of especial importance are the urine, feces and sputum. In pneumonic cases the sputum is laden with bacilli, and in delirious cases is a dangerous source of infection, as the bacilli may be spread broadcast about the room and over those in attendance. Here the resistance of the organism to dryness is of great importance.

Owing to hemorrhages in the stomach cases in which vomiting is present are liable to infect the surroundings. Pus from buboes and serum from primary sores, etc., are also infectious. The cadaver is teeming with organisms, consequently is a source of infection until destroyed.

Naturally, all attendants are continually exposed to these various sources of infection, and it is astonishing that so few of them contract the disease. Perhaps the constant exposure develops a sense of precaution carried out in the minutest details. Many instances of direct transmission of plague from lower animals to man are on record, but generally speaking, direct transmission plays an unimportant rôle in the dissemination of plague; as an evidence, the small number of attendants in plague hospitals contracting the disease may be cited.

*Indirect Transmission.*—Here the degree of viability and virulence of the organism is an essential feature. As the *Bacillus pestis* is a long-lived organism, and as the excreta, etc., are ladened with bacilli, all material coming in contact with the sick or kept in houses in which patients have been kept may serve to harbor and transport infectious material to those handling these goods.

Dust arising from infected places may be infectious for an undetermined time, certainly much longer than was formerly supposed. No positive evidence to show that water may transmit the disease is at hand. Perhaps the most fruitful sources of infection are the dark, poorly ventilated, filthy houses inhabited by the lower classes. There the organisms might easily remain alive and virulent over long periods, to be picked up by the unshod or otherwise exposed inmates.

Perhaps the best evidence of the importance of indirect transmission is the fact that those well protected by good clothing and shoes and living in fairly good hygienic condition rarely contract the disease.

In conclusion, it may be said that plague sprang from Egypt, formed new endemic homes, and traveled along the routes of commerce. The *Bacillus pestis* is long-lived, and may be carried from place to place in merchandise, by rats, etc., and by convalescents; the disease thrives best in unhygienic places, and the lower classes are mostly affected.

---

## THE PROPHYLAXIS OF PLAGUE.*

J. J. KINYOUN, M.D., Ph.D.
GLENOLDEN, PA.

The *sine qua non* in plague prophylaxis is the diagnosis. This is not so easy a matter as some are led to believe. The many forms which plague infection may assume, taken together with its insidious character, the inexperience of the medical profession of a given place, may render its recognition extremely difficult, even notwithstanding the fact that accurate methods of examination can, with certainty, be relied on to detect it.

The chief difficulty, however, which confronts one is that it may be so easily diagnosed as one of certain diseases of local origin, which it may so closely resemble, that it is an easy matter to overlook it. If the first cases were of the frank type—the bubonic—the task would be made easy. As a rule, this does not occur, and the ease in recognizing them as advocated by some is more a theory than a condition.

The clinical manifestations of plague are almost as varied as those attributed to malaria. Cases may resemble in whole or in part, and have been confounded with anthrax, pneumonia, diphtheria, bronchitis, pleurisy, pericarditis, endocarditis, peritonitis, appendicitis, rheumatic, typhoid, typhus, relapsing and malarial fevers, miliary tubercle, dysentery, beri-beri, syphilis, venereal bubo, mumps, septicemia and adenitis.

While it goes without saying that if it were the custom or the rule to apply accurate examinations to all cases in the foregoing list, nearly, if not all, the first cases would be detected, but we know that there are so many obstacles in the way for such procedures that it would be impracticable to carry them out, even if the medical profession were willing or able to do so.

If, on the contrary, all the first cases of plague infection were to be found in well-appointed hospitals, where accurate observations could be carried out, these would give us little concern. But this does not obtain. The first cases, as a rule, do not go to hospitals; in fact, only a few filter in, the greater number being found in localities where one is least expecting them and usually among a class of persons who naturally oppose the unwarranted (?) and presumptuous interference of the health authorities, or the physician who may have suspicions. Many cases occur under these conditions, and are not seen by anyone before the services of an undertaker or coroner are required. It is remarkable how resourceful this class of persons is in attesting to the non-infectious nature of the malady which has carried off their relative and friend.

To give a few illustrative experiences on the difficulties of a diagnosis: A case of illness occurred in San Francisco which, clinically, was that of typhoid fever, and passed muster as such, and three weeks later the autopsy and bacteriologic findings were those of plague. Another case was clinically that of diphtheria, but no cultures were made from the throat; antitoxin was administered when the case was moribund. During his last hours, while in delirium, he coughed and spat in the nurse's face, some of the sputum entering the eye. The nurse was immediately immunized with a large dose of diphtheria antitoxin. Despite this precaution she became ill within less than 30 hours, and died of an acute fever four days later. Autopsy revealed an acute septicemia, due to plague. Another gave a typical clinical history of lobar pneumonia, and the death certificate was made out accordingly. The room in which the patient died was closed for two weeks, when it was occupied by a woman and child. Four or five days after occupancy both became ill, one with bubonic, the other with pneumonic plague. A case was diagnosed as phlegmonous erysipelas, and was treated as such for 10 days, but on postmortem examination plague bacilli were isolated from the phlegmonous tissues, the heart's blood and spleen. Another case occurring soon after certainly did present the evidences of acute myocarditis. The blood, however, showed leucocytosis and pest-like bacilli. The autopsy was confirmatory of plague septicemia.

In Hong Kong I saw in consultation a case which all of us agreed was one of acute appendicitis, requiring immediate surgical interference. The blood showed considerable increase in the number of white blood cells, and many malarial parasites. The surgeon concluded to wait until quinin had been administered. On the next day the patient was worse, temperature higher, slight effusion into the peritoneum. The operation was deferred, and death occurred on the next day. Autopsy revealed a plague infection of the retroperitoneal glands near the appendix. In a case of a child in Manila presenting all the symptoms of a catarrhal pneumonia, autopsy confirmatory, the bacteriologic examination showed the cause to be plague bacillus.

The macroscopic appearances of organs and tissues of pest infections are, as a rule, quite distinctive. There is a respectable number of these in which there is scarcely anything suggestive of plague infection; yet the bacteriologic examination will reveal pest bacilli in all. Mixed infections may also be misleading, as instanced in the case diagnosed as appendicitis and in cases of beri-beri with an intercurrent infection of plague.

A vessel arrived at one of our quarantine stations with many cases of beri-beri aboard. Several had died en route or soon after arrival. Specimens of organs removed from a case just dead were examined bacteriologically and the pest bacillus isolated. The macroscopic, as well as the microscopic, appearances of the tissues were typical of those of beri-beri.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

The lesions observed in a respectable number of plague cadavers, both in San Francisco and in Hong Kong, were about as varied as one could wish to see. Those in Hong Kong occurred at the time of year which might be termed, for want of a better name, the post-epidemic period when the disease was declining; that is to say, when the number of cases were fewest. In these, the frank bubonic type was of rare occurrence, the septicemic type preponderating. Probably many of these do occur during the time when the epidemic is at its height and are overlooked. These cases certainly do occur in the pre-epidemic period and are not recognized as plague. Some of these are mild, ending in recovery; others are disposed of under a mistaken diagnosis. Viewed from a public health standpoint, these cases are of the greatest importance, and are, it is believed, one of the chief sources perpetuating the infection. These are some of the obstacles which stand in the way of a correct diagnosis, and are mentioned simply to emphasize the importance of making a careful and painstaking examination of every case wherein there is a possibility of plague infection. If such could be done, the majority of these masked cases would be recognized, yet some will be overlooked, even after the most painstaking examination, because of our inability to isolate the organism *intra vitam* or postmortem.

Plague, like cholera or bacillary dysentery, may show the same variations of virulence. It may be at first slight, and require a time more or less long before it assumes a virulence sufficient to cause an epidemic. On the other hand, it may remain for a long time in a locality making but little progress. Climatic conditions play no small part in its epidemicity. In such places as Hong Kong, Canton, Amoy and Manila it is certainly influenced by the temperature and humidity. The disease begins to assume its epidemic character during the warm rainy season, gradually increasing in intensity until the end, when it declines. It has been noted that when the temperature reaches 80 F. and is constant it declines gradually, reaching its lowest ebb just before the rainy season begins again.

While this condition obtains in the aforementioned places, it shows quite the opposite in California, where the greatest number of cases have occurred during the dry season. Seasonal influences appear, then, to have also something to do with the type of the disease, particularly in Hong Kong, where during the rainy season the majority of cases are bubonic; in the dry season, when the temperature is high and constant, nearly all the cases are septicemic. Just why there are these variations in type, or frequency of infection, can not be explained.

The ambulant type is not so much a factor in the dissemination of plague as some have been led to believe. The experiences of the health authorities of Hong Kong, Manila and at the Japanese ports all agree that these cases are extremely rare. My own experience, while not so extensive as that of others, is confirmatory. During 1899 to 1901, in over 50,000 persons examined for the apprehension of just such cases, out of these not more than 6 suspects were found—two on a vessel undoubtedly infected. These were kept under surveillance and a most rigid examination made of them; yet, notwithstanding this, the cause was not found to be other than plague.

The disease is a filthy one, and, like water, seeks its level among conditions which are ideal for its propagation and dissemination. Some years ago I made a statement that so long as the Chinese exclusion act was in force there would be little or no danger of the introduction of plague from the Orient. Since then I have learned that the Chinese exclusion act does not exclude, in the strict sense of the word, and particularly so from a health standpoint. There is a constant interchange going on of the Chinese coolie population between China, the United States and its territories, this interchange being provided for by special regulations. There also must be considered a number of persons who are debarred under the provisions of the act who seek admission through other channels not contemplated or specifically provided for. There can be no question that a respectable number of such persons do gain entrance to the United States. Another feature in the trans-Pacific traffic is the increasing importations of commodities from the Orient, which must be given due weight as a factor in the transmission of plague. It is farthest from our purpose to cast undue reflections on our own people, but there are certain conditions at present existing and constantly increasing which can not be viewed without concern.

There are many localities in our country which by reason of climatic conditions and race habit are ideal for the propagation of plague. The constant influx of foreign populations of low standard gravitating to many of our urban centers, is gradually forming the nucleus of material for epidemics, and is by reason of this influx becoming a serious problem in our public health work. With regard to the Chinese population, it is without doubt the worst of all as regards plague. There are now about 120,000 Chinese located in the United States, the majority of whom are on the western coast. These are controlled, and I may say absolutely, by that great and powerful organization known as the Chinese Benevolent Association, or The Six Companies. The rule of this organization over its subjects is as autocratic as the Sultan of Morocco or the Shah of Persia. The Chinese of the eastern coast are controlled by another organization of similar nature which is no less autocratic. These two instances are cited to show the manner of controlling the Chinese, and because bubonic plague has appeared among this people, and for offering an explanation in part of the difficulties which have stood in the way of its eradication among them. Some observers believe that little or no progress will be made in the detection of cases of plague among the Chinese, if a postmortem examination is insisted on, because of the strong race prejudice against them, as it will tend to the concealment of cases and more harm will follow than good accomplished. From our own observations this is only partly true. It is not so much due to prejudice of the Chinese against the examinations so much as their fear of their tong, or tribal customs and government being interfered with by western ideas. The Chinese desire to be let alone. The depositing of their dead on the streets, the concealment of cases, or the surreptitious removal of the moribund to the "Halls of Tranquility" is not so much their fear of a desecration of the dead as that of interference with their commercial and social life by the sanitary authorities. A careful examination of all sick of a Chinese community where plague is once detected, and a postmortem examination of all dead is the only way in which all plague cases will be found.

### MEASURES TO BE DIRECTED TO THE INDIVIDUAL SUSPECTED OF BEING AFFECTED WITH THE PLAGUE.

The suspected case should be isolated. The isolation should be all the term implies. Pending the completion of a diagnosis the same care should be exercised as if it were proven to be plague, and as soon as the examination is complete it should be removed to a hospital provided for infectious diseases, where the dangers of infection can be best controlled and where the case can be medically and humanely treated.

The premises in which the case is discovered should be regarded as infected—doubly so if it can not be definitely proven that the infection was contracted elsewhere. The house should be evacuated and be immediately closed. Sometimes, however, the condition of the case is such that it can not be removed; if so, it may be necessary to assume an extra risk and convert the premises' into a temporary hospital. As soon as the premises are ready to be evacuated provisions should be made for not only the care and treatment of those sick, but of those who have been in contact with it. These should be under observation in a non-infected place long enough to demonstrate their freedom from infection.

The premises and contents should be disinfected immediately after their evacuation by persons who are thoroughly conversant with the work, by the following methods: (*a*) by gaseous disinfection; (*b*) by mechanical cleansing; (*c*) by chemical disinfectants; (*d*) by steam; (*e*) by burning.

Great care should be exercised in the application of measures for the destruction of vermin, not only in the house itself, but in the immediate vicinity. If rats or mice are found dead in these places a bacteriologic examination should be made of these places to determine whether they are infected, as much depends on the thoroughness in which this feature is carried out.

After completion of the disinfection the house should be thoroughly aired. The soil in and around the premises may be such as not to exclude the possibility of its containing the plague bacilli, and if such be the case, it should, of course, be subjected to such processes as would sterilize the surface at least.

Suspects may be divided into two classes: 1. Those coming in direct contact with the case. 2. Those who have not come in contact with the case, but who have lived in the same house or in close proximity thereto. These may or may not be in the incubative stage. If so, the advisability of administering prophylactic injections of anti-pest serum must be considered, or perhaps the protective inoculations of Haffkine.

Too much importance can not be given to the destruction of vermin, and should not in any case be confined to the premises or those contiguous thereto, but should include a careful search for sick or dead vermin in a considerable zone around the infected premises, together with the destruction of all vermin. The crusade against vermin should be conducted for a sufficient length of time to be doubly sure the danger of their infection is past. This does not mean a few weeks, but should be persistent for months, or even a year or more after the last case of human plague.

The crusade against the rat population in San Francisco during the past winter demonstrates that it is infected. Just to what extent it is not safe to say, as the number examined is entirely too small to base an opinion on, but so far it has shown a greater number of infections than has been observed in Japan; in fact, nearly as large as in Hong Kong. It is, therefore, not safe to say that because no pest rats are found for two or three months the epidemic among rats has disappeared.

There are many rats in San Francisco. Judging from my own observations, together with those of two of my colleagues, the number is beyond computation, especially so along the water front. In the Chinese quarter, fortunately, there are fewer rats. Possibly this may partly explain why there has been so few cases of plague, but even if it were so it does not lessen the danger of the rats becoming infected along the water front. It is safe, therefore, to state that the rat population of San Francisco is stationary, as the few destroyed is a mere bagatelle. What should be done is to institute a systematic and thorough campaign against the rat, which should take in the whole city.

(*To be continued.*)

[The discussion on the papers of Drs. Calvert and Kinyoun will follow the conclusion of Dr. Kinyoun's paper next week.]

# ORTHODONTIC FACIAL ORTHOMORPHIA.

## IMPORTANCE OF DIFFERENTIATION IN CASES OF APPARENT MANDIBULAR PROTRUSION.*

WILLIAM ERNEST WALKER, D.D.S., M.D.
NEW ORLEANS.

Quite a little has been written on the etiology and treatment of cases presenting the appearance of protrusion of the mandible, the "chin-cap" treatment being recommended in young subjects and the removal of sections from each side of the mandible in older patients, and of late much has been written regarding the technic of this latter operation.

In a recent article Dr. E. H. Angle mentions a case in which this operation was successfully done in St. Louis[1] and tells of a failure having been made in New Orleans.[2] I have heard rumors in New Orleans concerning this failure, but have never seen the case.

Much has been written about treatment and a little about etiology, but apparently very little thought has been given to diagnosis, and the object of this brief paper is to emphasize the importance of a correct diagnosis on which to base an intelligent prescription.

It appears to have been taken for granted that the case which has the appearance to the surgeon of being a case of mandibular protrusion must necessarily be such, but I think that by presenting a case illustrating the erroneousness of that assumption, I can make it evident that this is not a fact.

From boyhood this patient was in the hands of a prominent dentist, who more than once was asked if anything could be done to remedy the defect; the invariable reply being "No, except in case the patient be willing to undergo a surgical operation for the removal of a section from each side of the mandible." The patient, at the age of 19, called on me, and my first impression was, as his brother had previously told me, that his lower jaw was very prominent.

Study of the case, however, convinced me that it was very much less a case of mandibular protrusion and very much more a case of arrest of the superior maxillæ.

Without explaining the diagnosis to the patient, he was allowed to return to his dentist, to whom he stated that Dr. Walker had told him that his case was remediable without a surgical operation, and again the dentist expressed as his opinion that nothing could be done for him except the operation previously mentioned, and that if Dr. Walker could otherwise remedy the defect, and if the patient had confidence, a trial might be made.

[1] Dental Cosmos, April, 1903.

[2] Items of Interest, April, 1903.

I mention these details to emphasize the perfect satisfaction the dentist manifested in his own diagnosis and prescription, notwithstanding its erroneousness, and to thus emphasize the necessity for the word of caution I am uttering, in order that errors in diagnosis may be avoided, for, on the diagnosis the treatment depends, which makes for success or failure.[3]

The patient has been taking a rest for some months, waiting for the alveolar process to redevelop around the teeth in their new position, which has now taken place and we are about to carry the upper teeth a step further. This waiting was considered advisable in order not to carry the teeth too far away from the bone, and because it has been found that if these periods of rest be given, the teeth can be moved great distances, the alveolar process developing around the teeth in their new position just as it did originally, and as it does after fractures, provided that the teeth are held still.

We know that in some pathologic conditions in adult life there is a great difference in the ability of the alveolar process to reproduce itself, but the movements of the teeth in alternating periods of activity and rest so closely resemble physiologic processes that Nature assists us by placing energetic osteoblasts at our service.

In the present case, the space made by the moving forward of the bicuspids and oral teeth, has been closed by the moving forward of the second molars, assisted by the developing of the third molars for which room has thus been made.

The next step will be to apply an apparatus which I am now constructing and which will have the effect of moving the maxillary teeth forward, using the chin and forehead as anchorage. This apparatus will somewhat resemble a baseball mask, but will have to be worn only during the night, the molars affording anchorage to retain during the day what we have gained during the night.

I hope by limiting myself to this one phase of the subject to so focus your attention on the subject of differentiation as to give it sufficient emphasis to attract the attention of the profession to its importance.

## DISCUSSION.

Dr. Eugene S. Talbot, Chicago—It is necessary to understand the etiology in order to treat these cases successfully. It is unfortunate that in this country the majority of the men treating these cases are merely mechanics. Indeed, one of the best men in the country in this line of work says he doesn't care for the etiology, that it is enough for him to be able to treat the conditions. It requires a great deal of time and study to understand the manner in which these conditions are produced, and in order to study this one particular phase we must go back to the time of Aristotle. Aristotle laid down the law of economy of growth, whereby a structure or organ is lost for the benefit of the organism as a whole. All students in evolution have based their work on that law. This law of economy of growth is illustrated in many structures, but those of the face, jaws and teeth are the most important to us. They are being lost for the benefit of the brain. This is one cause for so much decay in the teeth, and arrest of development of the jaw results in irregularities. Man in his evolution has atavistic tendencies so that in those patients who are called neurasthenic and whom I call degenerates, in whom there is an arrest of development, there is also frequently excessive development. This is illustrated by the picture of Charles V. of Spain. History records that Charles V. suffered from indigestion all his life; that he could not eat, and that he kept ten cooks preparing foods for him. Two hundred years after his death a photograph was taken of his skeleton in the coffin, showing this type of face. With the mouth closed the upper teeth closed inside the lower jaw. At that time there were no orthodontologists, and therefore he could not have his teeth regulated. The lower jaw is a movable organ, and because of this it is frequently more fully developed than the upper, which, attached to the bones of the skull, becomes arrested in development and causes this marked deformity. It is possible that the lower jaw in some cases will be excessively developed and there atavism enters. If such cases are taken at the age of thirteen, when the alveolar process is in a constructive stage, there is a possibility of moving these teeth and having the alveolar process remain with them. If the correction is made at the age of 20 to 24, there is more force required, producing inflammation in the alveolar process and preventing its restoration. Therefore, I question how far an operator is justified in correcting irregularities of the teeth. I have known patients to suffer from one to three years from nervous prostration as a result of regulation of teeth by dentists who did not know they were operating on neurasthenics. I do not believe the ordinary dentist should undertake to treat these cases, but it should be done by one who is medically educated and familiar with the nervous system.

Mr. T. E. Constant, Scarborough, England—Very often in the condition where the upper incisor teeth appear to protrude we find that a study of the etiology results in showing a still greater deformity. In many cases diagnosed as superior protrusion the condition is really one of inferior retrusion. If a good bite is obtained after the teeth have been moved, the result ought to be permanent, but this will depend on how the teeth occlude.

Dr. M. H. Fletcher, Cincinnati—I fully agree with Dr. Talbot in his condemnation of the efforts of incompetent men to do this work. I have had three cases sent to me almost in collapse from the ineffectual efforts of men who apparently understand nothing about the work and who had no conception of the stress to the patient under these circumstances. These cases resulted in absolute failure and a wholesome fear on the part of the patient. The varying conditions of health, and the surroundings at home, have great bearing on these cases. I undertake to see that the child has the co-operation and encouragement of the home people. The child must have normal recreation and not too much study.

Dr. H. E. Belden, New Orleans—I agree with Dr. Talbot that the operation carried on in adult life does not always meet with perfect success, especially where a good deal of motion is required. It is not only hard to move the teeth, but often difficult to retain them in their new position. An example is the case of a young lady whose teeth protruded so much that she could not cover them with her lips, and she was much disfigured. Ten years ago I brought the teeth back to their normal position with such success that she is often complimented on her fine teeth—but to hold them in position she still wears a retaining band every night. I agree with Mr. Constant that if the occlusion is good we are more apt to have a successful issue. We see many bridges which can not be worn because of inaccurate occlusion. On the other hand, we see bridges that have lost their attachments, and sometimes natural teeth which the patient can remove from their sockets and replace at will, but they can be retained and made use of on account of their bite.

Dr. Walker—Showing how little the treatment interfered with this man's nervous condition, I may remark that he took during the treatment a two years' course of law in one year and graduated. He has not yet secured occlusion. This we hope to obtain later. The patient tells us that he had not much pain, a little at the first. The bands worn were always stationary.

---

[3] Here the patient and others were exhibited, as were also plaster casts, showing the full-front face and profile of the patient before beginning treatment; and also casts of the upper and lower teeth in their relative position at that time; also casts showing the face, front and profile, and the teeth, two months and a half later. Casts were also shown showing the relative positions of the upper and lower jaws at the time of reading the paper, the patient being present for examination and for comparison with the plaster casts.

Dr. M. L. Rhein, New York City—It is unfortunate that a certain class of men in this country having a false sort of dental education with some mechanical dexterity, appear before the public as advertised specialists on orthodontia. I believe in stomatology as a specialty of medicine, but I am opposed to any further subdivision of the work. I believe that the stomatologist should have the entire care of the individual mouth under his charge and if the distinctive and individual portions of the work are to be divided up for the better method of execution, it all ought to remain under his personal supervision. The amount of damage that is done by men improperly qualified is very great. It is my opinion that work can not be commenced too early in these cases of irregularity. The same principle is brought out here as in the work of Lorenz. The softer the bones are when we handle them, the more easily are they molded and the better are the results. I have attempted a number of corrections after the age of twenty, and the results have never come up to my hope. It seems almost impossible to get occlusion, that is, what might be called self-locking. I have at present under treatment two patients aged 8 and 9 years. The parent had doubts whether to have work commenced at the time, and the opinion of a number of men was sought. A large number of the profession have the idea that work should be delayed until all the permanent teeth are erupted. I take exception to the view that the fixed apparatus for spreading the arch is less painful than a removable one. There is more than one way of applying an apparatus. I know of none that will work so painlessly and so easily as that devised by Dr. Ottolengui. I agree that if the work on the bones can not be done without giving pain and causing nervous tension there is a mistake somewhere, and that much harm will be done the child. These patients come to my office sometimes as often as four times a week without any evidence of nervous depression.

Dr. Walker, New Orleans—Dr. Talbot made a reflection on the effect of this work on neurasthenics. The child referred to is a most decided neurasthenic, but since I have been working on her teeth her health has been manifestly improved daily. As the treatment continued, her mental, physical and nervous condition became better. I think this has been partly due to the self-control I have caused her to exert. Heretofore the least disturbance would cause her to cry. Dr. Rhein has stated that the work should be practically painless. He is undoubtedly right. The old way of regulating with movable appliances did cause a great deal of pain and damage to the nervous system. With the fixed appliance, however, the soreness does not ensue. I have used Jackson's appliances since 1894. It is the system to use when the teeth are coming in. If the teeth are in place, a fixed apparatus is better because a greater force is required than can be secured with the Jackson appliance without producing soreness. I think no one system should be adhered to, but that the good from all should be selected for the case to which it is adapted. We should undoubtedly avoid producing pain on account of the injury to the nervous system. In cases in which not much pressure or a great degree of speed is needed I feel that a removable apparatus may be employed. Mr. Constant is correct in saying that many cases of inferior retrusion are diagnosed as superior protrusion and so treated and the patients, therefore, disfigured. In regard to specialization, I think more will be accomplished by a man taking up a specialty after a number of years spent in general practice, and then working in sympathy with the general practitioner.

# THE DENTAL PULP—VIEWED WITHOUT THE MICROSCOPE.*

THOMAS E. CONSTANT, M.R.C.S.
SCARBOROUGH, ENGLAND.

Before entering on the subject-matter of the present paper may I be allowed to express my appreciation of the honor conferred on me by the invitation this Section of the American Medical Association—an association which enrolls in its list of membership names which are known to and revered by scientists all the world over. The invitation was not accepted without diffidence, for the subject allotted is a narrow one and the investigators many and devoted—indeed, it may safely be affirmed that during the last decade no structure in the human body has been more often or more closely scrutinized than the dental pulp. The majority of the observers have, however, given most attention to those points which require the microscope for their elucidation, and it is partly on that account that I intend to-day to confine myself to the macroscopic aspect of the subject.

The human dental pulp has been arbitrarily defined by an American writer as commencing during the fourth month of fetal existence. Prior to that time it is the "dental papilla." This distinction is convenient, and, although I am ignorant as to whether it has been given general acceptance in this country, for the purposes of this paper I shall adopt it.

At the end of the fourth month of fetal existence dissection reveals the pulps of the milk teeth as translucent gelatinous substances which roughly correspond in shape to the crowns of the teeth which are respectively formed from them. They are generally described as lying in a shallow groove or gutter of bone which is all that exists at that period of what is later known as the alveolar portion of the jaws. The pulps are severally surrounded by a membrane to which they are not anywhere adherent except at their bases. Between the investing membrane and the pulp there is always a fluid which John Hunter likened to the synovial fluid in joints. In the case of the lower animals this fluid is often found in considerable quantity. The membrane is, of course, the tooth-sac. What the fluid is I do not know. By stripping the periosteum from the jaws the tooth sacs and their contents can be removed entire from the gutter of bone in which they lie. At this period (fourth to fifth month) when the dental sacs have been thus removed the groove in which they lie is found to be traversed in the incisor region by slight ridges which form the commencement of the alveolar septa between the incisor teeth. On opening the tooth sacs they are found to be adherent below to the tooth pulps and above to blend indistinguishably with the oral mucous membrane. The apices of the pulps show signs of commencing calcification, the incisors being tipped with little caps of bony material. As calcification proceeds these caps gradually increase in thickness and extend downward over the sides of the pulps, and at the end of nine months of fetal existence the central incisors are about two-thirds calcified, that is to say, the edge of the calcified caps almost reaches the bony floor on which the pulp rests. In the meantime the bony gutter has undergone a marked transformation. Its edges have grown up around the pulps, and the transverse ridges already mentioned have also grown up, forming complete septa between the developing incisor teeth. In the same way the pulps of the developing cuspid and molar teeth have been enclosed, bony septa, of which there was no indication at four months, having sprung up. Thus each developing tooth has become enclosed in a separate crypt, the floor of which is formed by the original gutter of bone, the labial and lingual walls by the upgrowth of its edges and the mesial and distal by the upgrowth of the bony septa. Most of the text-books state that it is about this time (nine fetal months) a roofing in of the crypts takes place by an arching over of the walls. Thus Broomell writes in describing the development of the crypts:

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

> Beginning with a simple groove, or gutter, into which the tooth follicles hang, the follicles exerting a controlling influence over its form. Next comes the appearance of septa between the anterior follicles, which at this period are somewhat irregularly placed in the arch, followed in a few weeks by a well-defined partition between the cuspids and molars, until finally, at birth, each follicle is enclosed in its individual crypt, with the single exception of the second molar, in which the distal septum, or that which is to separate it from the first permanent molar, has not yet made its appearance. As the tooth follicles increase in size by the development of the teeth within, they become more perfectly enclosed in the bony vaults, the sides of the alveolar walls arching over and almost completely enclosing the developing teeth.

Tomes, speaking of the condition of the mandible at the time of birth, quotes: "The alveolar margins are deeply indented with large open crypts." As a matter of fact, both of these descriptions are incorrect, for in the nine months fetus and at birth the crypts are completely closed. It is true that the bone which forms the roof of the crypts is very thin and parchment-like, but it is always there. Broomell is wrong, too, in his description in so far that he makes it appear that the roof is formed very late and by an arching over of the walls. The roof, such as it is, is complete before the bony septa between the various teeth; and what is usually described as a groove or gutter is really a tunnel with a very thin bony roof. There are one or two specimens in the museum of the Odontological Society of Great Britain which illustrate this very clearly. At birth, then, the dental pulps and their partially calcified crowns are completely enclosed in bony crypts. In any dry specimen in which this bony roof is found complete the external surfaces of the calcified crowns within the crypts are invariably found to lack the luster and vitrified appearance one finds on the surface of adult teeth. In a crypt from which the roof has been partially or wholly absorbed the tooth crown is found to be completely calcified; from which we may, I think, infer that completion of the process of amelification is the necessary prelude to absorption of the roof of the crypt. At the time when this absorption occurs the bases of the crowns are in closer contact with the floors of the crypts in which they are contained than at any other time, but there always intervenes, of course, the vascular tissue which marks the junction of the tooth sac and the pulp.

"But," I think I hear you saying, "what has all this to do with the dental pulp?"

Gentlemen, I wish to introduce that interesting structure to you in a new rôle. As the active agent in the formation of dentine we have all known it from our earliest student days. Those of us whose privilege it is to be engaged in the practice of dental surgery recognize it as the mutual friend at whose urgent persuasion the more reluctant of our clientele are induced to seek our society.

It is, however, in the unfamiliar character as the active agent in the translation of the teeth from the crypts in which they originate to the position they finally occupy in the mouth that I wish you to make the acquaintance of the dental pulp to-day. To do this it was first necessary to remind you of its anatomic relations, which have been altogether ignored by the authors of the various theories which from time to time have been advanced to explain that interesting developmental process which we term "eruption of the teeth." Before stating the case for the dental pulp let us pause a moment to consider these theories.

One of the oldest of them is that the eruption of the teeth is due to the elongation of their roots. As long ago as 1835 Thomas Bell wrote: "As ossification proceeds, the roots of the teeth continue to elongate, until first those of the incisores, and subsequently the others, can no longer be contained within the alveoli." This theory is still very popular, but against it the following insuperable objections have been raised: (1) That the distance traveled by the crown of the tooth is sometimes greater than the length of its root. (2) That teeth with comparatively little root sometimes erupt, while others with fully formed roots remain unerupted; and (3) that teeth with roots fully formed may remain unerupted for some length of time and then subsequently erupt.

The following quotation from an article by Dr. Pierce, entitled "The Eruption and Structural Relations of the Deciduous and Permanent Teeth," in the "American System of Dentistry" (1887) clearly shows that there are some writers who even yet regard this theory with favor. He says:

> The absorption of the superimposed tissue from the advancing crown, and the elongation or growth of the root by an increase in the pulpy mass or formative tissue and its calcification are the progressive developmental processes which we term "eruption of the teeth." The force by which the teeth are propelled toward and through the mucous surface into position, is thought by many to be something in addition to that indicated above as the result of normal growth.

In explanation of the eruption of teeth with unformed roots, Dr. Pierce writes in the same article:

> The question at once arises whether such premature presentation of the tooth crown is not wholly due to an absorption or wasting of the superimposed tissue, rather than to the elevation of the crown, which could not well take place without the growth of root, unless it were from the contraction or an expulsive effort of the tooth follicle.

The same writer offers the following ingenious explanation of the eruption of teeth with roots that were fully formed some time previously:

> There is a mechanical force, however, acting on all such teeth, tending to bring them to the surface, the same as on an unantagonized tooth, inducing its elongation or protrusion from the socket. The repeated closing of the jaws must exert to a large extent this mechanical force, just as the bung in a barrel is elevated by a blow being struck on the stave or either side of it.

Tomes' explanation of the same phenomenon is not quite so ingenious, but, as will appear later, is not less unsatisfactory. His account of the eruption of a canine tooth of a human female at the age of 45 is as follows:

> Supposing it, then, to be admitted that the tooth was completely developed before the process of cutting commenced,

the process in itself must be in some respects different from that which occurs when teeth are cut under ordinary circumstances. When the process is normal as respects time and the stage of development of the tooth, the crown appears through the gum long before the root has attained its full length. The crown is in great part brought toward the surface of the gum by the progressive lengthening of the root, and is afterward still further raised by the same process. Now, when the eruption is accomplished subsequent to the development of the root, the movement of the tooth must be effected by some other means than by the progressive lengthening of the root. The completed tooth has to change its place without itself undergoing any change. The bone which stands in its way must be absorbed, and the lower portion of the socket from which the root of the tooth emerges must be contracted by the deposition of the bone. Indeed, in the absence of a better hypothesis it may be assumed that the gradual contraction of the socket is the means used by Nature for bringing teeth to the surface when the process of eruption has been delayed beyond the normal period. In the one case the movement is effected by the development of bone within the alveolus, in the other by the progressive development and consequent lengthening of the tooth.

Another theory that for a time held sway was that of Delabarre. The following account of it from Harris' "Dental Surgery" (1863) is almost touching, and shows the fascination it exercised over lovers of analogy:

> The able physiologist and learned dentist, Delabarre, has advanced a most ingenious theory on this subject. He believes that the passage of a tooth through the gum, or rather its escape from its crypt, is effected in precisely the same manner as is the birth of a child. He regards the sac attached above to the gum and below to the neck of the tooth as the chief agent in the eruption, and believes that it is by its contraction that the latter is raised from the bottom of the alveolus and ultimately forced through the dilated orifice of the capsule and gum. This is the most rational theory that has been advanced; it explains on principles of sound physiology this most wonderful and curious operation of the economy.

This romantic theory lost favor chiefly because its most ardent supporters were unable to demonstrate the slightest resemblance between the dental sac and the female organ to which they imagined it was analogous. It would not have been included here were it not that a passage in one of the above quotations from the writings of Dr. Pierce indicates that the theory has not yet lost its pristine power.

It must have been the improbability of Delabarre's theory that encouraged Coleman to propound another, the acceptance of which would involve the abandonment of existing views as to the growth and development of the jaws. He imagined the teeth to be carried to the surface by a series of "bone currents," in other words, by interstitial growth of bone peculiar to the jaws, and then laid bare by the absorption of the alveolar margins. The reluctance displayed by our leading physiologists to lay aside their views as to the growth of bone, and to accept Coleman's, no doubt largely accounts for the modified enthusiasm with which his theory has been received. The greatest objection to it, perhaps, apart from this is that while it accounts more or less satisfactorily for the eruption of the teeth, it fails to explain how it is that some teeth never do erupt. It is difficult to imagine a lateral or canine tooth stemming the tide of bone currents that its immediate neighbors have found it impossible to resist.

Another theory is that the teeth are raised by a deposit of bone at the bottom of the crypts in which they are contained; and yet another (which is the last to be considered here) is that the teeth are forced into their destined places by contraction of the alveoli. Of these two theories the latter would only account for the eruption of such teeth as have a single conical root, because in case of teeth with two or more roots such contraction would tend to retard rather than assist eruption; while the former rests on an assumption for which, as we shall presently see, there is absolutely no foundation.

I would here draw your attention to Figure 1 which represents a specimen in the museum of the Odontological Society of Great Britain. It shows as clearly as possible that the distance of the bottom of the crypt containing the second molar from the inferior dental canal is very little less than the distance of the apices of the roots of the first molar from the same landmark.

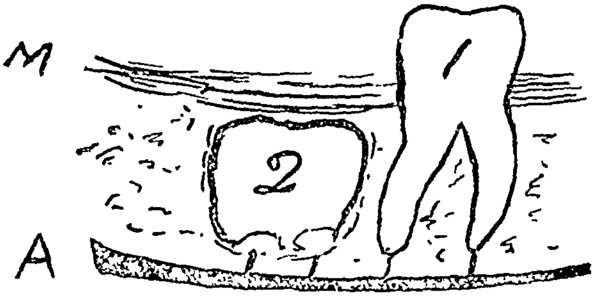

Fig. 1.—First molar. 2. Second molar. A. Inferior dental canal. M. Oral mucous membrane.

It is clear, therefore, that the eruption of the first molar could not have been due to bone deposition on the floor of its crypt. Reference to the same illustration will also convince you that narrowing of the alveoli containing the roots of the first molar would have retarded rather than assisted its eruption.

It appears to me that the chief objection to the root elongation and bone formation theories is a physiologic one. It is extremely difficult to conceive such a process as dentine formation exercising independent mechanical force. But, granting that it may be so, on what structure is that force exercised—in other words, to put the matter clearly and concisely, if somewhat vulgarly, what does the root shove against?

Since the forming root is never in actual contact with its bony surroundings, it must necessarily be against the vascular material in which it is embedded. Now, this tissue appears postmortem of far too jelly-like a consistence to oppose any effective resistance by virtue of its own structure—and yet such resistance there must be or the tissue would be obliterated. Whence, then, are its resisting properties derived? Necessarily from the blood pressure. Therefore, assuming that the physiologic process of dentinification can exercise independent mechanical force and is a factor in the causation of eruption it must, since action and reaction are equal and opposite, divide the honors with the blood pressure—a factor hitherto quite unrecognized. Indeed, it is obvious that any *vis a tergo* must act through

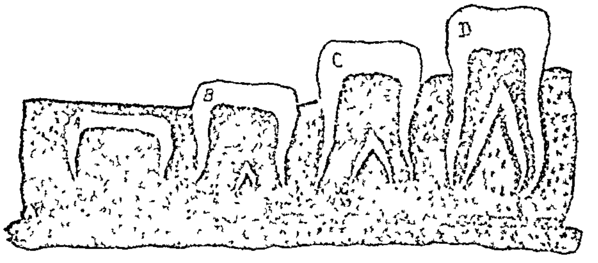

Fig. 2.—Section through a lower molar tooth.

the vascular material surrounding the root; and it follows that such force can not be greater than the blood pressure or it would cut off the blood supply to the root.

But is a force other than the blood pressure a necessary hypothesis when we consider the exceptionally advantageous conditions under which it acts? Let us illustrate these conditions by a diagram (Fig. 2).

A, B, C and D represent a section through a lower molar tooth and its crypt at various stages of development. In A it is obvious that the pulp forms a fleshy column of vascular tissue on which the crown really rests. The pulp itself is injected by the force of the blood pressure entering almost directly from A′, an artery of considerable size. Under the calcifying margins of the crown is the pad of tissue that forms the junction of the sac and pulp, and between the crown and the walls of the crypt is the vascular tooth sac which is injected from the same source as the pulp. Above the crown is the oral mucous membrane and submucous tissue. Now, it is obvious that the blood pressure exerted in the pulp tissue acts on the crown at a considerable mechanical advantage in comparison with the pressure in the tissues overlying the crown. Indeed, it is only necessary to glance at the diagram to understand how it is that some teeth travel so quickly to their destined position when once their crowns have emerged from the gum. In fact, with regard to this point, it is a marvel that dentists who have many opportunities of observing the rapidity with which teeth sometimes move during eruption should ever have been induced to regard the comparatively slow process of dentinification as the active agent in the matter. As eruption proceeds so does root formation, the former making space for the latter. Indeed, if I may be allowed to illustrate the process in a homely fashion and in the way it presents itself to me, the mechanism is somewhat similar to that employed by a sweep in cleaning a chimney. I do not know whether you, in this country, have improved on our method of "chimney-sweeping," so perhaps I had better explain that our sweep employs a circular brush and a bundle of rods with screw joints. He places the brush in the chimney and screws in the first rod, then he pushes the brush up the chimney the length of the rod and then screws in another rod, and so on. Now, the sweep represents the pulp, the force he uses to push the brush up the chimney represents the blood pressure, and the screwing in of a fresh rod represents the various stages of root formation.

Referring again to the diagram, we notice that each stage in the formation of the root diminishes the extrusive tendency of the pulp until when the root is complete *it becomes practically nil.* Moreover, after the tooth crown has emerged from the gum the tooth sac, which has now become the peridental membrane, forms a ligament for the tooth, being attached both to the roots and to the socket. The vascularity of this membrane still endows it, however, with an extrusive tendency which is in itself sufficient to account for the gradual elongation of unopposed teeth, and is probably the chief means by which the proper occlusion of opposing teeth is maintained. If we have any doubt in the case of healthy teeth as to whether this elongation is due to the normal blood pressure exerted in the peridental membrane they should surely be dispelled by the clinical phenomena that present themselves when the blood pressure is pathologically augmented—in other words, when inflammation of the peridental membrane supervenes. When we consider the mechanical conditions illustrated by the foregoing diagram in conjunction with the pulsating and expansive force exercised by the blood pressure does not the necessity for another eruptive force disappear and Dr. Pierce's bung-and-barrel explanation of the elongation of unopposed teeth become somewhat superfluous.

If we assume that the blood pressure, acting in the manner above described, is the sole active mechanical factor in determining the eruption of the teeth, will it account for the phenomena other theories fail to explain? That the crown of the tooth sometimes travels *a distance greater than the length of its root,* that teeth sometimes erupt subsequently to the formation of their roots, and that teeth with comparatively little root occasionally erupt, are facts all in favor of such hypothesis and can be explained by it.

The fact that teeth with fully formed roots remain unerupted can be more easily explained by this theory than by any other, because it alone can account for the space obtained for the fully developed roots which often occupy abnormal positions. In other words, the blood pressure, acting as it does equally in all directions, makes room for the developing root in the direction of least resistance. Normally this is in the direction of the advancing crown, but occasionally it is elsewhere. The continuous eruption of teeth with persistent pulps, which neither Delabarre's nor Coleman's theory could possibly explain, is a very simple problem if we admit the blood pressure as the active mechanical factor.

I am, therefore, of the opinion that on anatomic and physiologic grounds alone are we justified in assuming that *the blood pressure exerted in the vascular tissue which lies between a developing tooth and its bony surroundings is the active mechanical factor in the process known as the eruption of the teeth.*

So far the purely mechanical aspect of the question has been alone considered; but if your patience will endure the strain there are one or two points of physiologic interest that have so direct a bearing on the subject that it would be as well to include them here.

Some years ago I recorded the observation that in young people, when a back tooth had lost its antagonists, the characteristic elongation which takes place under those circumstances varied in cases in which the pulps of the unopposing teeth were dead from those in which they were living. In the former instance, although the elongation of the teeth took place, it was unaccompanied by any downgrowth (or, in the case of a lower tooth, upgrowth) of the alveolar ridge; whereas, in the latter case, there was a corresponding deepening of the alveolar ridge. In other words, in the case of dead teeth there was simply extrusion from the alveolus, but in the case of living there was growth of the alveolar ridge. It appears obvious, therefore, that the growth of the alveolar process is dependent on the integrity of the dental pulp; or, in other words, that the pulps of the teeth, as a whole, exercise a trophic influence with regard to the alveolar process. I am of the opinion that extirpation of the pulp of a tooth causes a marked and permanent alteration in the vascular condition of the peridental membrane—in fact, a disturbance of vasomotor equilibrium in the direction of a paralysis of the vasoconstrictor mechanism.

The foregoing remarks apply to both the permanent and temporary dentitions; but the pulps of the temporary teeth exercise another kind of trophic influence which seems to have escaped the notice of dental writers, namely, their influence on the process of resorption of the roots of the temporary teeth. In the case of temporary teeth, in which the pulps are destroyed at the time when resorption of the roots should commence, resorption, strictly so-called, does not occur at all. In such cases a certain amount of absorption of the root, as a rule, takes place, just as it often does in the case of dead permanent teeth, the macroscopic appearance of the roots in both cases being strikingly similar. This absorption is a pathologic process and differs markedly from the physiologic process of resorption. It is a much slower process, and that is one reason why we so frequently find the apices of the roots of dead temporary teeth protruding from the labial or buccal surfaces of the alveolar ridges, causing that ulceration of the mucous membrane of the cheeks or lips with which we are so familiar in the case of children whose milk teeth have been neglected.

The explanation of this common phenomenon is simple. The death of the pulp of the temporary tooth has left its root incapable of resorption and its socket prone to degeneration. Absorption is too slow a process to make room for the crown of the permanent successor which soon impinges on the dead root, deflects it and thrusts its apex through the degenerated alveolar process and the superjacent soft tissues. In those cases in which death of the temporary tooth has taken place some time after the process of resorption has commenced and the root is, in consequence, shortened, the pressure of the advancing permanent tooth simply tilts the root until it takes a nearly horizontal position; the crown, if any remain, being correspondingly deflected. Other phenomena which admit of a similar explanation are familiar to us all, and need not be enumerated.

From the time when the dental pulp is "nothing more than a part of the mesoblastic myxomatous tissue of the jaw, which has become more rich in vessels and cells than the other neighboring part" up to the time when commencing senile degeneration presages the termination of its physiologic activity, it is one of the busiest exponents of local government observable in the whole domain of human physiology. While it is hard at work constructing the tooth it regulates the blood pressure that causes that organ to travel to its appointed place in the mouth, at the same time building up the bony walls that enable that pressure to act at a mechanical advantage. Then, in the case of the temporary teeth, it superintends the demolition of the very structure it has been at such pains to create; and finally, in the case of the permanent teeth, it controls the nutrition of those parts on the integrity of which the tooth is dependent for the proper exercise of its function. Thus we are able to understand the otherwise inexplicable phenomenon which Tomes aptly describes in the following words: "It is impossible to insist too strongly on the fact that the sockets grow up with, and are molded around, the teeth as the latter elongate. Teeth do not come down and take possession of sockets more or less ready and pre-existent, but the socket is subservient to the position of the tooth; wherever the tooth may chance to get to, there its socket will be built up round it. On the proper appreciation of this fact depends our whole understanding of the mechanism of teething; the position of the teeth determines that of the sockets, and the form of pre-existent alveolar bone has little or nothing to do with the disposition of the teeth."

[The discussion on the symposium of papers by Drs. Constant, Morgenstein, Causch and Römer will follow the paper of Dr. Römer in a later issue.]

# THE IMMEDIATE RELIEF OF HYSTERICAL MANIFESTATIONS OF THE LARYNX.*

HANAU W. LOEB, A.M., M.D.
Professor of Nose and Throat Diseases in St. Louis University.
ST. LOUIS.

Hysterical manifestations in the larynx are common enough to fall frequently into the hands of every laryngologist. The treatment likewise is successful enough to warrant an almost positive promise of relief in at least the majority of cases. There is, however, much to be learned, both as to the development of newer and more satisfactory methods and as to the reasons for the successes in individual cases.

It is in view of these circumstances that I present my method which, though original with me so far as I know, may yet have been used by others. I do not assert for a moment that the method results in anything but a relief from the laryngeal symptoms or that monosymptomatic hysteria exists, and that, therefore, the symptomatic relief is tantamount to a cure. Nor is it certain that the relief is of any longer duration than that from other plans. But it is clear that the method is simple, absolutely painless, easy of application and withal successful.

All plans of treatment have as their basis the deception of the patient, or, perhaps I should say, direction of the patient's mind away from false conceptions toward possibilities that are within his reach if only he will utilize them. In other words, suggestion in one form or another is used. This may be extended over a period of time, or it may be so decided that it is effective at the first sitting. To the former class belong such plans of treatment as manipulations of various kinds and operations distant from the seat of the symptoms. Often, too, operative interference in the neighborhood of the larynx or applications to the larynx or pharynx will be followed by relief after a longer or shorter time. Consecutive treatment of any kind may have a similar effect in ridding the patient eventually of his symptoms. Immediate suggestion, on the other hand, is mainly used through the medium of a strong electric current which is sent through the larynx, and generally becomes effective at once.

The method which I desire to detail is of this type, but it requires no instrument except the index finger and a ready tongue on the part of the operator.

At the first sitting, having recognized the case as one of hysteria, I state to anyone who happens to accompany the patient that the case is quite clear and easily relievable, but, turning to the patient, I say: "You must agree to let me do what is necessary. I can not consent to undertake the treatment unless you are willing to submit yourself to the treatment." The patients invariably say that they are willing to stand anything provided there is any likelihood of a cure. Of course, I give an absolute promise as to relief and send the patient home to think and to worry about it, or, if it is desirable, proceed at once to work. In any event, I generally deliver a short and more or less sentimental talk to aphonics on the word "home," which I state is the first word that they will utter, the most beautiful and easiest to pronounce in the English language. Having secured the requisite confidence and interest, I place the patient on a chair and I insert the index finger of the right hand into the pharynx and press the epiglottis over the glottis until the patient becomes somewhat uncomfortable, when I withdraw my finger and say in a loud commanding voice, "Now, say 'home, home, home!'" The patient responds and the command is continued as often as necessary until the patient repeats not only "home," but any word suggested, and leaves the office talking as well as anyone. At the next sitting I look into the larynx and state that everything is in perfect shape and the treatment concluded.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

Of course, the character of conversation must be modified as the requirements of the individual demand, but in the main the procedure above indicated may be adopted.

In my earlier cases I stated that there was a dislocation or defect in the larynx which my treatment would relieve, but I now make no statement of what I affect to discover in the larynx in consequence of the advice given to me by Dr. Schwab. He called my attention to the fact that hysterics are prone to adopt suggestions to their own detriment, although the suggestion be made for their relief. In two of the three relapses the error of this plan was shown. In the first case one of my patients (which one, I do not know) called on my assistant during my absence in Europe and said that she had another dislocation in her throat and that I had cured her before by sticking my finger down her throat and invited him to do the same. He did so, and she became phonic again.

In the other case, that of hysterical mutism, the recurrence, I am sure, was made possible by my error in detailing the supposed cause.

The cases to which the method has been applied cover the whole range of the commoner hysterical manifestations of the larynx, such as aphonia, mutism and cry. The result was in every instance successful except in one not reported here for the reason that I did not have a fair opportunity to do the necessary work. The case was one which I saw for a few moments only in the office of Dr. Freudenthal of New York during a visit to that city. The case was a very obstinate one, having been the rounds of laryngologists without benefit. The Doctor had been unable to relieve her, and asked me to try my plan. Of course, I could not and did not secure the patient's confidence and, therefore, nothing resulted.

The cases which I report will fairly demonstrate the variety of conditions that may be relieved and likewise the method of applying the suggestion. Of course, in every instance, I explained the nature of the condition and the character and true facts of the treatment to some sensible member of the family. To do otherwise would have placed me in the ranks of the charlatans. The responsible member of the family is entitled to know that there is no real operation, and that the method used is purely one of suggestion. It is best, generally, to postpone giving this information until just before resorting to the suggestion. Of course, it is necessary to enjoin the informed not to let the patient know the true facts and not to discuss the condition with the patient or friends.

General treatment is indicated in all these cases, especially such as may influence the hysteria, which is the basis of the condition that causes the patient to consult a laryngologist.

### SUMMARY OF CASES.

CASE 1.—*Hysterical Aphonia, Paralysis of Adduction.*—My first case was that of a girl, aged 17, who came to my clinic suffering from the classical symptoms of hysterical aphonia. After showing her to my students and demonstrating the hysterical paralysis of adduction, I endeavored to pursue the usual plan of sending a current of electricity through the larynx. My battery was out of order, so being at a loss for an agent with which to influence the patient, it occurred to me that I might accomplish the same result by suggesting that something was dislocated in the larynx which I could easily replace and thereby accomplish a cure. Somewhat to my surprise the patient recovered her voice as soon as I withdrew my finger and announced that everything was in proper order again.

CASE 2.—*Hysterical Aphonia, Adductor Paralysis.*—In January, 1900, I was asked by Dr. Jacob Geiger of St. Joseph to see a young girl, E. B., aged 13, who had been suffering from aphonia for six months. This had come on suddenly and had not yielded to treatment, which had been, in the main, nerve and blood tonics and sprays. There was no previous history except an attack of acute rheumatism some years before. The girl was of a very lively, nervous disposition, very capricious and somewhat anemic. Having learned of the case beforehand, and readily recognizing the condition, I had sent word to the mother that her daughter would speak within two minutes after I saw her. As a consequence of this the patient was prepared for something extraordinary. I made a hurried examination and confirmed the diagnosis and stated to the patient that if she were willing to submit herself to the treatment, however severe it might be, I would have her saying "home" in less than a minute. She consented. I adopted the usual plan, and withdrawing my finger suddenly, commanded her to say "home, home, home." She did so, and acting on my direction she called up her grandfather by long-distance telephone and within three minutes after I saw her she was talking to him in proper voice for the first time in six months. There has been no recurrence, as I learned from Dr. Geiger, under whose charge the patient now is.

CASE 3.—*Hysterical Aphonia, Adductor Paralysis, Anesthesia of the Pharynx, Hysterical Cough.*—The father of A. B. had written to me, in May, 1900, from Louisiana describing his daughter's condition. He stated that she had lost her voice suddenly eight weeks before, and since that time could whisper, but not phonate. He asked me to telegraph if I could relieve her. Knowing well what the effect would be on the young lady, I telegraphed to him that I could cure his daughter. As I surmised, when she arrived she was perfectly satisfied that I would cure her, and I had little difficulty in making her have full confidence in what I promised. As usual, I advised her that the operation which I should perform would necessarily be a severe one. She stated she was willing to stand anything. Unfortunately, a well-disposed patient, who became acquainted with the one whose case I am reporting, assured her in a sympathetic way that the operation would not be painful and that she need not have any fear. To this I lay the necessity of making three efforts before I was successful. I found the patient, when she came into my operating room, very much calmer and not disposed to fear the operation. After I withdrew my finger the first time, her voice was slightly more phonic. Looking into her throat I stated that the cords were not in proper position. I made another effort, this time with more success, for now she spoke in a rather hoarse but fairly phonic way. After examining the larynx I stated that it was almost in the exact position which I wished it. The third effort was successful. Since that time there has been no return whatever. Curiously, after the disappearance of the aphonia she developed a hysterical cough, which, however, lasted only a few weeks. Dr. Bauduy, who examined the case, confirmed the diagnosis of hysteria. The mother was intensely hysterical, and immediately after the young lady's voice returned I isolated her from her mother for three days, fearing the effect of her sympathy and the maternal hysteria. In this case during the attack the cords could not be approximated, during the efforts at phonation the space between the arytenoids being fully 7 millimeters. Anesthesia of the pharynx was marked.

Case 4.—*Hysterical Aphonia.*—F. M., aged 22, first lost her voice suddenly in September, 1900. One week later it returned suddenly. Two weeks after this the voice again disappeared suddenly and reappeared within one week. The last attack came on a month before she consulted me, which was on Dec. 18, 1900. This attack differed somewhat from the other in that she could not even whisper at first, but a week before she began to whisper again. There was no pain, no discomfort and no globus hystericus. Her general health was good, but she was somewhat anemic. Previous health had been good. I made an examination, stated that there was a condition in her larynx that required immediate attention, lectured to her on the easiest word in the English language, namely, "home," assured her that this would be the first word she would speak, and having thoroughly frightened her, secured her consent to go through the necessary performance on the following day. She returned very much worried, very much interested, and determined to undergo anything to recover her voice. The usual plan was adopted and her voice returned immediately, and there has been no recurrence of the aphonia since.

Case 5.—*Hysterical Mutism, Adductor Paralysis, Hemianesthesia, Anesthesia of the Pharynx.*—I was consulted in November, 1900, by Mrs. M. G., a widow, aged 41, who presented the following history: In February, 1899, an operation was performed on the right axilla. After this she remained in bed for four months. July 1 she found it impossible to phonate, her voice becoming suddenly of a whispering type. Aug. 2, 1899, her voice was lost altogether, it being impossible for her even to whisper. Since that time she has been unable to phonate or to whisper. She stated that she had never been able to speak in a loud tone since the operation, and evidently ascribes her trouble to the operation. There was no definable cause for either the whispering or the attack of mutism. She states she had a choking sensation, after which her voice disappeared. Her mother died of consumption when the patient was 5 years old. Her father died in the Army from a wound. There was no nasal discharge and there were no symptoms of throat trouble, except that she complained that her throat felt sore on the right side (the side on which the operation was performed). She had frequent attacks of headache of the migraine type, both sides being affected. The attacks came on without any special regularity. There was no cough, no expectoration, no clearing of the throat. Her appetite was fair; her bowels regular; no difficulty of respiration; occasional choking sensation at night; general condition fair. Both Dr. Chaddock and Dr. Schwab, who examined this patient at different periods, found unmistakable evidence of hysteria, and numerous stigmata, such as hemianesthesia, anesthesia of the pharynx, etc. The patient, who had been suffering from mutism for 16 months, was brought before my class, giving me an occasion to make a distinct impression on her as to the seriousness of her condition, the possible severity of the operation and the beautiful influence of the word "home," the first word which she learned she was to speak in 16 months. Of all the patients whom I have treated in this way she was most affected. She responded at once to treatment and her voice returned. On Sept. 25, 1902, she again consulted me on account of the loss of voice of two days' duration. I found a very acute inflammation of the pharynx, tonsils, lingual tonsil and larynx. The usual remedies were applied, and though the acute inflammation disappeared the aphonia continued. It was evident that she remembered her previous attack, and was probably influenced by a fear that there had been a second dislocation in the larynx. Not desiring to complicate the matter, as it was evident that suggestion in this case had as much power for evil as for good, I concluded to use another method in this case. Consequently, I made an application to the lingual tonsil of a strong solution of nitrate of silver, having stated to her without undue explanation that she would be enabled to talk immediately thereafter. Success followed this application.

Case 6.—*Hysterical Aphonia, Hoarseness.*—Miss M., aged 24, consulted me in December, 1900, on account of her hoarseness, which had lasted for six months. Two years before I had endeavored to relieve her of hysterical aphonia by galvanization with but indifferent success. She could phonate at times, but her voice was always hoarse, while she had occasional relapses into complete aphonia. Her general health was fair, though she was nervous and disposed to be melancholic. One sister suffered from melancholia for two years, but finally recovered. Examination showed that the vocal cords did not approximate when phonation was attempted. The usual plan was followed, and although such a case could not offer the same promise as one of complete aphonia, the patient entirely recovered, and has continued free from trouble except occasional attacks of hoarseness, which, however, last but a short time.

Case 7.—*Hysterical Cry.*—I. S., aged 13, consulted me in April, 1901, at the instance of Dr. B. L. Dorsey, with the following history: She had been more or less sick all winter with what was designated nervous prostration. Other than this there had been no trouble except painful spots along the right leg. About three months previous to this time the peculiar shrill cry first appeared and within the limits of its characteristics it had continued since that time. The cry did not appear until 4 o'clock in the afternoon (after school) and it continued at intervals of from one and a half to two minutes, until she went to sleep. From that time until the succeeding day at 4 o'clock she was free from its presence. The cry, which lasted about two seconds, resembled the sound of a prolonged *ai*, and the intensity was about that of the voice of a child when calling another at some distance away. The quality, duration, pitch and intensity, so far as I could observe or learn, were about the same under all conditions, whether the child was on the street or in the house. The girl was very much mortified about her condition, and strove to conceal it, manifesting great disinclination to leave home. Examination of the nose, pharynx and larynx showed nothing abnormal. Dr. Chaddock found stigmata of hysteria, which naturally confirmed the diagnosis. Although this case hardly afforded the scope for suggestion after the method detailed that the aphonic cases offered, it was finally decided to adopt the same plan. Accordingly, after the usual preliminaries and after being assured by the patient that she was willing to stand anything which would afford relief, I inserted my finger into the larynx until she became very uncomfortable, and withdrawing it, suddenly, I said, "Now you are all right!" I then examined her larynx and stated to the Doctor and mother that everything was now perfectly normal. Since that time she has never had a single attack. I saw her last in March, 1903.

Case 8.—*Hysterical Aphonia, Anesthesia of Palate and Pharynx.*—Miss E. P., aged 27, referred to me by Dr. F. J. V. Krebs, Dec. 1, 1902, lost her voice six months ago. Two months later without apparent reason her voice returned. Two months later it again disappeared, and since that time, although much had been done to relieve her, the aphonia persisted. The patient's health had been fair, but she was nervous and easily excited. On attempted phonation the cords would move spasmodically to and fro with a short range about 5 millimeters from the median line and would finally come to rest in the position of complete abduction. Palate and pharynx were anesthetic. After the usual preliminaries, I inserted my finger into the larynx and, withdrawing it, I ordered her to say "home, home, home!" She responded in a fairly loud voice. As I continued to direct her to say this and other words, I noticed that there was still a tendency to aphonia in that she would quite often whisper the word instead of saying it aloud. I then asked her to sing "home, sweet home," and with the assistance of my own somewhat discordant tones she sang the song and the aphonia left her. Three months later there was a recurrence, which readily responded to my suggestion which comprehended an inspection of the larynx, an expression which indicated that I understood the condition and the introduction of the finger without comment. Since this she has had no further attack.

## DISCUSSION.

**Dr. Frank W. Hilscher**, Spokane, Wash.—The method of treatment is on the principle which Dr. Mulhall of St. Louis described ten years or more ago. I remember seeing in his clinic a case of hysterical aphonia, treated by inserting a wet sponge electrode into the pharynx which frightened the patient so that he made an exclamation. The patient was then commanded to speak on penalty of a repetition of the operation. This same patient would lose his voice occasionally, relapsing into the former condition, but the physician had no trouble renewing the suggestion, going so far that he actually produced the suggestion by telephone. That was done in at least one case of which I know, and he told me that he had accomplished a similar result in a number of other cases.

**Dr. J. F. Barnhill**, Indianapolis, Ind.—I consider this paper as one of distinctive value. Cases of hysterical aphonia exist, and when we are consulted concerning them, knowledge of a certain method such as Dr. Loeb suggests becomes as valuable to us, trivial though the method may seem, as is the technic of the most complicated surgical procedure. I have treated some cases of this kind, one lately, in which there were lingual tonsils. I assured the patient that the removal of these would result in the cure of her ailment, and verified the prediction to the satisfaction of all concerned. I desire to ask Dr. Loeb two questions: 1. Has it been his observation in the class of cases he has described, that the pharynx and larynx are in an anesthetic condition? 2. He stated that the epiglottis is pressed down with the finger until there is considerable discomfort. Is it the intention to cause the patient pain by this pressure, or are we to understand by the term discomfort that some degree of asphyxia is produced?

**Dr. H. Dupuy**, New Orleans—The success Dr. Loeb obtained from positive hypnotic suggestion promises excellent results in these cases. A girl of 19, a religious enthusiast, came to my office with an acute case of hysterical aphonia. I examined the parts thoroughly, and by way of suggestion I told her that there was something up behind the nose that caused the disturbance. I introduced my finger and made the manipulations we usually do for the recognition of adenoids. Her voice was immediately restored. Several months afterward the aphonia recurred and she was unwilling to again undergo what she considered a heroic maneuver. I would like to ask Dr. Loeb whether he has had any recurrences, and what is the longest time in any case in which there has been no return of the aphonia.

**Dr. C. M. Cobb**, Boston—I was told in the Hospital for Epileptics that there is often some serious constitutional idiosyncrasy or dyscrasia back of hysteria and that these patients often become insane or have tuberculosis later. The same suggestion was made by Dr. Edes of Boston. He said that he used to consider them almost immortal, but that they are not; the death rate among them is much higher than among normal individuals. I am very glad Dr. Loeb has given us the details of his treatment by suggestion. Probably every one who has practiced medicine any length of time has invented a method of suggestion of his own. One physician's method was to talk with the nurse outside of the door within the hearing of the patient, in the case of a married woman, for example, as to whom the husband was likely to marry if the patient did not recover. The nurse would suggest someone and the physician would say that it met his approval, since the woman was good and strong. The result would be that the patient recovered her voice speedily.

**Dr. H. W. Loeb**, St. Louis—Personally I knew nothing about hypnotism or suggestion previous to this work, and I know now practically nothing about it. I have been forced to report this method, which differs from the other methods in its systematic performance. These patients, however, are prone to accept suggestion, not only for their relief, but also to their detriment. In one case, for instance, the patient came to have a new dislocation restored. In Dr. Barnhill's case an operation was found necessary; it is possible that that woman will have some operation performed on every part of her anatomy before she is through. Those are the cases the neurologists complain that we treat with the ablation or supposed ablation of some organ, and the disease returns again and again. Such conditions as anesthesia and hemianesthesia may be relieved in the same way as aphonia. If we use heterogeneous suggestion we may often make mistakes. In the last few cases I have said nothing about the condition found; I simply look at the larynx and say that I will be able to cure the trouble. One case is of at least two years' standing. The pharynx is not always anesthetic, but it is often so in hysterical cases. As to the discomfort resulting from the treatment there is, of course, no pain, but only an impediment to respiration. I occlude the larynx until there is a distinct impression from the suffocation, then withdraw the finger and command them to speak and they simply can not help talking. I hope the members will use this method with caution, not to use a suggestion that may be duplicated and do the patient harm.

## THE TREND OF MODERN PSYCHIATRY AND ITS RELATION TO GENERAL MEDICINE.[*]

JOHN PUNTON, M.D.
KANSAS CITY, MO.

Amid the kaleidoscopic changes incident to modern medical progress, none are more conspicuous and striking than those which pertain to the study of psychiatry. To the average practitioner medical psychology was until within a very recent period, a sealed book, and even to-day its study is greatly neglected by many of our medical schools and colleges.

This indifference is well understood, however, when we remember the hypothetical character of former available knowledge concerning morbid psychical phenomena, as well as the difficulties which beset its practical clinical application in general medical practice. Moreover the numerous exigencies that belong to the care, management and treatment of the insane soon led the general practitioner to lose interest in its study, and all such cases were willingly referred by him to those members of our profession whose tastes or opportunities led them to select this form of practice, hence, the alienist became through sheer force of circumstances the first in chronologic order of medical specialists.

As insanity at times requires rigid isolation, hospitals devoted to the exclusive use of the insane were imperatively demanded, but cheerfully supplied from the generous funds of the state treasury. Owing to the extreme magnitude of such hospitals their control became a very tempting prize for rival political parties to possess, hence their management was soon added to the political spoils system.

The universal adoption, however, of this diabolical political practice imposed a great injustice on the unfortunates who were compelled to submit to its evil consequences, beside proving a serious hindrance to the progress of scientific psychiatry. Moreover the exclusive character of the work soon led the medical officers to separate themselves from the rest of the medical profession, which had the baneful effect of not only dwarfing their own medical growth, but also retarded the study and development of psychologic medicine. Not all of the medical officers were tainted with this special vice, but the general correctness of the assertion can not successfully be denied.

Without any desire to be pessimistic, and duly recognizing that in the development of the modern insane or psychopathic hospital with all its scientific paraphernalia, our forefathers necessarily were compelled to pass through the period of what may be termed the mechanical stage of construction, at which time, perhaps, the size of the hospital, together with its more purely mechanical devices, such as the washing machines, steam cooking utensils and the electric lighting apparatus, was even of greater importance than its purely medical equipment or the more strictly scientific methods belonging to the study of psychiatry, yet we believe the time has now come when these purely mechanical matters can safely be left, in a large part, to others, reserving at the same time the right of the medical superintendent to be the chief ranking officer, to whom all such matters can be referred for final judgment, while his first and chief duty, as well as those of his assistants, should be the scientific study of insanity, as well as the best means for its appropriate care, prevention and treatment.

---

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

That this ideal is far from being realized in several of our state institutions, at the present time, is clear to all thoughtful physicians, and that many of them are still practically owned and controlled by the politicians is common knowledge. In this dilemma it was evident that something needed to be done in order to extricate the insane hospitals from their unfortunate predicament by rescuing them from the hands of the politicians, and at the same time infuse new medical life and spirit into the officers comprising the medical staff, by reminding them of their great weakness in thus isolating themselves from the rest of the profession, as well as emphasizing their unusual opportunity for scientific clinical and pathologic psychiatric research which they were wholly neglecting.

Fortunately for us the man and the occasion presented themselves about 8 years ago, and, while this great work of deliverance is still in its early infancy, yet the results so far attained are flattering, while to their honor let it be said the brilliant achievements already accomplished by the rescued medical officers have largely redeemed the former careless indifference into which they had unwittingly fallen. Prior to the able address[1] referred to, which was delivered before the American Psychological Association, May 16, 1894, by Dr. Weir Mitchell of Philadelphia, in which he severely criticised prevailing methods of the officers, as well as the care, management and treatment of the insane, little was actually being done of a truly scientific nature (except in a few notable instances), by those who had charge of the various state insane hospitals, to enlighten the general medical profession concerning the true nature and character of insanity. This bold and fearless address, however, has had the desired effect of arousing the alienist from his lethargic slumber to one of extreme zeal and scientific activity, which has resulted in a continual series of practical demonstrations and discoveries that greatly enlarge our former available useful clinical knowledge concerning the insane, as well as the intricate problems associated with psychopathology and clinical psychiatry.

While it is true that the alienist was first of medical specialists, yet he soon become too exclusive in his methods to be practical, and his willing isolation stunted the growth and development of scientific psychiatry to such an extent that there was complete stagnation in this department of medicine for very many years. Dr. Mitchell's address, however, marks the beginning of a new era in the scientific study of psychiatry in America by defining the line of demarcation between the inactive, unpractical, unscientific methods of the past and those of the more modern, enthusiastic, energetic, scientific, practical ones of the present period. It also demonstrates conclusively the practical trend of modern psychiatry in thus repudiating political intrigue as the dominating controlling power which dictates the medical policy and appointments of our state hospitals, beside refusing politics the right to govern the standard of medical educational worth and fitness for such positions. To live out of range of critical shot and not be preceded and followed through the various wards of the insane hospitals by clever rivals in other departments of medicine, or to refuse advice and even admission to able clinicians working in other medical branches, was not only an ancient vice, but a method of doubtful practical utility which needed condemnation, as it certainly hindered the best growth and development of scientific psychiatry. Under the old régime of keeping aloof from the rest of the medical profession was it any wonder that a few years ago when the alienist was asked for his contributions to medical science that we were handed the latest biennial report of the hospital, which contained but a few fragmentary remarks concerning insanity, and sandwiched among incomprehensible tables of statistics and farm balance sheets, beside many pages devoted to the crying need of a new washing machine, additional buildings or more medical assistants?

That such was the case is a well-known fact (and unfortunately exists even to-day in a few of the more nonprogressive state hospitals), but the trend of modern psychiatry contemplates the revolution of such worthless matters by substituting in their stead the inauguration of a practical scheme whereby those called on to fill such positions of trust and honor can demonstrate their fitness by their individual scientific attainments and more willing devotion to the scientific study of psychiatry, thereby placing a premium on their meritorious service. That insanity and its allied disorders can not be separated or divorced from general medicine, but that the intricate problems associated with each are more or less dove-tailed, is self-evident, hence, it is impossible to ignore the close relation that exists between mind and body on the one hand, and general and special medicine on the other. It was not, however, until this intimate relation or bond of union between the two was better understood that the science of psychiatry made any practical tangible advance.

With every step in the forward, progressive march, however, connected with the study of neuropathology, it was evident that those diseases termed mental were dependent on some lesion of the nervous system, hence nervous and mental diseases are closely allied, indeed they are to be regarded as being almost synonymous, so that the study of one depends on the study of the other, and as all parts of the human organism are subject to nervous control or innervation it follows as a logical sequence that the entire human organism is concerned at times in their clinical manifestations. In order, therefore, to be a competent alienist one must of necessity be not only a skilled neurologist, but also an able general medical practitioner. That American alienists have been slow to learn this great lesson is certain, but it is a very hopeful sign of the times and one that also beautifully illustrates the trend of modern psychiatry, when we realize the truth that the American Psychological Association has ultimately decided to affiliate with the Congress of American Physicians and Surgeons by holding their meeting together next week at Washington, D. C. Such an amalgamation as this can not fail to accomplish much good to all concerned, as well as prove a valuable scientific impetus to the future study of psychiatry. In thus extricating the insane hospitals from their perilous political position, as well as win back to the common professional ranks this large and useful body of scientific alienists, Dr. Mitchell unconsciously exercised a masterly stroke of medical polity, as well as displayed shrewd strategetic diplomacy which argues well for the future study of psychiatry, beside forcibly illustrating the modern tendency of scientific exactness in practical psychologic medicine. That we are simply standing at the threshold of a practical working knowledge of insanity heretofore unattained by any previous period, whereby the general medical practitioner can recognize clinically from the varied symptom complex grouping, not only the evidence of diagnosis, but also the more important factor of prognosis, is very certain. This is clearly evident when we contemplate the progress recently made in psychopathology whereby our former conceptions of the acute psychoses have been greatly modified and revised, thus changing completely all former classifications of insanity, and rendering them more or less antiquated and obsolete.

---

[1] Jour. of Nervous and Mental Diseases, July, 1894.

In this advanced step of progressive medical development we see again the trend of modern psychiatry and recognize at once its practical clinical utility in general medical practice.

For centuries it has been the prevailing custom to classify insanity from either its etiologic, symptomologic, pathologic or psychologic standpoint, hence, those of us who learned our psychiatry within the past 15 or 25 years know full well how these earlier views were handed down and taught us, and how they still cling to our memory, thereby molding our forms of thought in classifying the more common types of insanity. It is only within the past ten years, however, that we in America have fully realized their faulty construction and that instead of considering such conditions as melancholia, mania and dementia, as distinct morbid clinical entities as was formerly taught and believed, we are now fully assured by the more advanced and correct views of Kraepelin that these are simply different stages of one and the same underlying pathologic process.

Hence, all former generalized schemes of classification which does not conform to this more correct teaching as demonstrated by modern clinical research and pathologic findings are not only proven to be wholly inaccurate, but utterly futile and misleading.

While these newer conceptions of insanity have been partially understood for some time, more especially in Germany, yet no systematic attempt to enforce their practical teaching in America took place until within the past few years, and at the present time there are but three text-books[2] to my knowledge published by American authors in which these newer and more correct views are set forth, thus embodying their establishment in American scientific medical literature. Without any desire to burden you with evidence of the fallacy of the older teaching by which these three common psychoses were considered distinct and separate clinical entities, it will suffice to remind you that it was very obvious to those who had large opportunity of practical clinical experience that changes in the emotional nature or variations in the states of feeling common to the sufferers of the acute forms of insanity were absolutely of too evanescent a character to be made the basis of any scientific system of classification.

These at best are unreliable guides, and, consequently, misleading, for under such a method any new symptom or group of symptoms in which there was a decided manifest change in the condition of the emotional element would suffice to establish a separate species of insanity. For instance it is clear to those who have had any experience that cases of melancholia often present symptoms of mania and later those of dementia. The conception of these very different mental states represented in the same individual as being distinct morbid entities, has long dominated psychiatric teaching. That this view was based on the changes in the emotional nature of the patient is evident, but such fluctuating states of feeling are now recognized to be altogether too misleading to form the basis of accurate scientific classification, hence Kraepelin's proposition to make the tendency of the underlying disease process, whether toward recovery or dementia, a criterion of the character of the psychoses is certainly helpful. In this form of classification all the elements are included which belong to its cause, symptoms, course, duration and final outcome, and each is given the proper recognition it richly deserves. From this standpoint melancholia and mania are considered due to the same pathologic process, and while we are as yet unable to satisfactorily explain its special pathologic character, the clinical correctness and validity of this position can not successfully be gainsaid. Moreover, clinical observation and experience demonstrates the truth of the assertion that, when this principle is applied to the acute psychoses, one group of cases naturally tends toward recovery, while still another class has a characteristic tendency toward dementia. On this clinical fact depends the future welfare of our patient, hence, in every case of acute psychosis we look from the outset for the prognosis, as in the former case a favorable opinion can safely be ventured, while in the latter case the prognosis is beset with serious misgivings. Thus it will be seen that the trend of modern psychiatry is toward simplification in classification whereby a single species of insanity takes the place of several under the older methods, as well as establishing a new criterion by which the essential tendency of the disease as a whole is recognized and its natural clinical character revealed in the form of either recovery or dementia, which again determines its favorable or unfavorable final outcome, thus establishing a correct rule for prognosis.

Again the trend of modern psychiatry can be seen in the movement whereby the more accurate or recent insane can receive appropriate accommodations and treatment at the various general hospitals of our cities rather than be referred, as they are now, to the state insane hospitals.

In making this statement I trust it will not be understood that I undervalue the service rendered these poor unfortunates by the medical staff of our state institutions—far from it, for I have the very highest regard for them and their work, as well as for the magnificent structures in which they dwell; but as it now stands, scarcely any general hospital will receive for treatment persons suffering from mental derangement. The reason for this is well understood, even though a great injustice is sometimes done by such a rule. In the majority of instances at the present time such general hospitals are not prepared to receive such persons because the very nature of the case requires special quarters and privileges which are not now supplied or available. Moreover, the environment of the medical and surgical wards of the average city hospital are not calculated to benefit the recent or more acute forms of the various psychoses, and this is often urged against their admission.

---

[2] Brower and Bannister: Practical Manual of Insanity. Reference Handbook, Medical Sciences, 1903. Berkeley on Mental Disease.

But there are several good scientific reasons why provision for this class of patients should be made in our general city hospitals. Indeed, it is highly desirable that such cases should be admitted, and it is one of the hopeful signs of medical psychiatric progress that such a movement has already been inaugurated. Perhaps the most important reason, and that to which all others would appear subservient, is the fact that in its incipient stage insanity is most curable. Indeed, it is infinitely more curable than typhoid fever, pneumonia or even rheumatism and kidney lesions. The curability of insanity in its incipient stage is so very striking that it appeals to our more serious consideration, and while this truism has been emphasized for centuries we are so very slow in taking advantage of its true significance that I make that my excuse for again urging its recognition and practical importance. How very desirable to receive such persons in the early formative period of the malady, before the more serious complications occur, such as delusions, imperative concepts or phobias, hallucinations, suicide, homicide, or even incoherence. That we are then enabled to study more especially the causes, whether they be toxic or otherwise, and thus gain control or stay the progress of cell disorganization or even remove the conditions which favor their development, is clear to all.

The dilly-dallying process, however, of waiting for further developments, as now commonly practiced on the part of both physician and the friends of the patient, would largely be removed if our city hospitals would receive such persons for treatment. Moreover, this unfortunate disposition to wait often decides the question of prognosis whereby a presumably curable case is rapidly transformed into one of absolute incurability. On inquiry we often find this failure to act promptly depends on one or more of four conditions, viz.: 1. Ignorance of the necessity of providing prompt and appropriate treatment. 2. Fear of the stigma which follows commitment or exposure of family secrets. 3. Failure to recognize that insanity implies irresponsibility and that suicidal complications develop early. 4. Lack of funds to defray the necessary expense involved in the treatment. All these elements cause the parties interested to hesitate before taking the necessary steps to provide suitable and appropriate treatment. If the general city hospitals would make special provision by adopting a psychopathic department for such patients and receive them at a moderate financial rate or even on the same basis as other patients are now admitted, the prevailing objections would speedily disappear and it would become as common to refer the insane to such hospitals for treatment as it is now those suffering from typhoid or pneumonia.

The special advantage of such an arrangement would certainly tend to increase the percentage of recoveries, which is always so highly desirable and which constitutes the true aim and object of practical scientific psychiatry. The more accurate systems of classification that are now enforced render finer discriminations in diagnosis possible, which again improve our methods of treatment. Hence the trend of modern psychiatry is toward greater individualized care of the insane. This is greatly aided by the more correct and improved methods of examination, which again depend on the more strictly scientific laboratory processes and modern mechanical appliances, all of which tend to enlarge our practical, clinical and therapeutical resources. In conclusion, it is my conviction that psychiatry has yet a great work before it, as well as a rich field for conquest in separating the various fads and frauds of the day and substituting in their stead scientific medical truth as revealed in the practical observation and experience concerning the demonstrated facts which pertain to mental influence and placing them on a practical scientific basis. That nervous and mental diseases are not always amenable to either pharmacology or surgery is very certain, but that they are powerfully influenced for good or ill by mental and moral means, as well as by the nature of their environments, is a statement in accord not only with our best knowledge, but also with our experience and judgment. That these psychologic means and measures powerfully affect the results obtained in their treatment is also very clear to every thoughtful physician, but that their specific nature as well as methods of application are not as well understood by the profession as they should be is also true. It would, therefore, seem within the legitimate province of the science of psychiatry to rid mental therapeutics of their empiric value by practical dmonstrations and by the teaching of the genuine, thus differentiating the true from the false by appropriate, practical methods, and recognizing their special virtue by placing them on a scientific, ethical basis. To sum up, it would appear that the general trend of modern psychiatry is toward more strict accuracy in classification and diagnosis of mental disorders by the practical utility of all the recognized modern means and methods known to medical science. These again establish a more correct rule for prognosis, besides suggesting a plan of treatment to be adopted for their relief, all of which, when duly applied by the general medical practitioner, will not only aid him in the differentiation of the various psychoses and allied disorders, but will also furnish him the secret to their more successful care, management and treatment, which, after all, is the true aim and object of all practical medical science.

## DISCUSSION.

DR. F. SAVARY PEARCE, Philadelphia—*I think we all agree that to send certain cases of acute insanity to the general hospital instead of to the insane asylum is not only practicable, but highly desirable. We know that certain cases of acute insanity will recover, and if such patients could be sent to a general hospital their recovery could be hastened, and they would be spared the stigma of having been inmates of an insane asylum. A special ward should be set aside for these patients in the general hospital; otherwise the general medical men connected with the institution will surely find legitimate reasons for objecting to the presence of this class of cases in the hospital. In the institution with which I am connected I hope in the near future to see a special ward set aside, as far distant from the ordinary wards as possible, where cases of acute insanity can be treated. Another point is that the members of the patient's family are often the very ones who insist that he be sent to an asylum. The physician must educate the public to the fact that insanity is not infrequently a curable disease. We know that a great many of the incipient cases of insanity, and even some of the chronic cases, recover. According to Dr. Richardson, of the Norristown Asylum, 50 per cent. of the cases admitted to the asylum recover. I am convinced that the treatment of the insane must be revised very thoroughly. If the public could be made to appreciate the fact that patients suffering from insanity recover as frequently as do those suffering from many other diseases, I am sure that they would give us their coöperation in the establishment of special wards for the insane* in the general hospitals. This would also rid insanity of much of the mystery that now surrounds it.

Dr. Daniel R. Brower, Chicago—It is not very long since I suggested the establishment of psychopathic wards in general hospitals. Since then, great progress has been made toward the realization of this project, and one of the most hopeful signs, as Dr. Punton has told you, is the amalgamation of the American Psychological Association with the Congress of Physicians and Surgeons. But this object is not always attainable. The maintenance of such a special ward is a very expensive affair. Since I gave up the medical superintendency of a hospital for the insane, I have been engaged continuously in the treatment of acute cases of insanity in a general hospital, and I think I have had a fair measure of success, sufficient, at least, to induce me to continue. Of course, cases that are treated in these general hospitals must be selected with care, and if that is done, a considerable number of them can be safely admitted. I wish to emphasize the point that it is possible, in well-selected cases of acute insanity, to get satisfactory results in the general hospitals.

Dr. R. Harvey Cook, Oxford, Ohio—In arguing for the admission of the acute insane into a ward of a general hospital, instead of a hospital for the insane, you imply either that the acute case can be better cared for in the general hospital, or you are endeavoring to prevent the stigma of insanity. If the acute case can receive better care, so can the more prolonged case. It then makes it imperative to convert our hospitals for the insane into general hospitals for humanity's sake. If, on the other hand, it be to avoid the stigma, how grossly unjust to the less acute case. Would it not be far better to place all insane cases in a hospital for the insane where proper classification can be had? Educate the people, let them know and feel that insanity is of no more disgrace than typhoid, thus removing in a short time the so-called stigma.

Dr. J. H. McBride, Los Angeles, Cal.—I think we are all gratified to note that a change has taken place in recent years in the treatment of the insane, and that more attention is paid to-day to general medicine in the insane asylums than ever before. In regard to the curability of insanity, I can hardly agree with Dr. Punton. I think his proportion of recoveries is too large. My own experience is essentially summarized in the statement of a French alienist, whose name I forget. He said that of ten insane persons, five would recover from the first attack, and five would not recover. Of the five who recovered, two, certainly, and probably three, would relapse; the other two, or possibly three, would remain well. This leaves a probable recovery rate of 20 or 30 per cent.

Dr. Richard Dewey, Wauwatosa, Wis.—What impresses me most in regard to this whole subject is the difficulty of drawing definite lines, and the danger in making sweeping assertions. Insanity is so complex a condition that it is scarcely possible to generalize. There is a large number of persons who are insane in the ordinary sense of the term, and who, nevertheless, can be treated in the general hospital; then there are other cases for whom that plan is entirely inadmissible. We must ascertain whether the form of insanity is associated with dangerous or disagreeable elements before we can decide whether a certain patient can be treated in a general institution. Some insane patients are noisy; others have suicidal or other dangerous tendencies, and for all such special provision must be made. I do not doubt the desirability of treating certain cases of acute insanity in the general hospital, but the cases must be carefully selected and suitable provision must be made for them in the way of isolated rooms. I believe that this question will eventually work itself out if each of us not only will do the best he can with cases that come to him, but also especially make an effort to enlighten the general profession and the community. This class of patients also requires freedom in coming and going under suitable regulation. They should spend much of their time out of doors, especially in the pleasant season of the year, and the city streets are not good places for insane patients. Institutions where they are cared for should be surrounded by grounds where these patients can get plenty of outdoor exercise. I greatly appreciate the fact that the subject of insanity does not occupy the isolated position it formerly held, and that this disease is now being studied very much in the same manner as are other diseases.

Dr. Albert E. Sterne, Indianapolis—For many years I held the view that so-called observation or reception hospitals would be very desirable in connection with the treatment of the acutely insane. In experiments that have been made in that direction, however, as wards in connection with general hospitals, it has been found that in the vast majority of those cases it became necessary to send them to an insane asylum after a comparatively short period of time. No alienist can foresee, in any given case, even of the mildest type, what the duration of the psychosis will be. He may in certain instances approximate its duration, but it is a rather common experience that the very worst cases of the acute variety of insanity, sometimes with the most unpromising outlook at the beginning, both as regards their personal aspect and the family history, may improve within a few weeks or even days, especially where the digestive element is a prominent one. Then, again, we have the experience that in the acute, seemingly mild cases, which we would prefer to send to the general hospital, the symptoms may steadily grow worse, and the patients may take weeks, months or even years to recover. No general hospital could possibly take care of these cases for any great length of time. It is unfortunate that a few insane must suffer with the general mass of the insane. It is unfortunate that a comparatively small percentage of persons who were insane for brief periods should have such a stigma placed on them. They could no doubt have been treated just as well, or even better, in a general hospital or at home. The Scotch plan of treating insane patients by the colonization method, which affords them plenty of freedom and out-of-door exercise, has proved to be excellent, but for the ordinary run of cases it would be found impracticable. The establishment of a detention hospital, separate from the main asylum, would be better. The fact has already been brought out that relapses are not uncommon among these acute cases. According to one of the German authorities, a vast majority of the cases of mania and melancholia suffer from relapses, and even in the interim it is a question whether they are entirely free from the disease. While I am an advocate of the detention hospital, I should not be in favor of separate wards for the acutely insane in the general hospital. I think such a measure would prove inimical to the majority of the patients in such an institution, and even, in the end, to the insane patients themselves.

Dr. William J. Herdman, Ann Arbor, Mich.—At the time Dr. Weir Mitchell made his strictures on the medical management of the insane asylums, I think he scarcely did justice to what was being done. In those years, the officials of many of the insane asylums were greatly handicapped by conditions under which they were doing some very good work. I know this was true in the Michigan asylums, and I was very familiar with them at that time. As we progress into a new field, we must go largely along the skirmish line, and do a great deal of individual work. In doing this, a man may not always be fully understood by his fellows. We have passed beyond that skirmish line now, and the main column is moving on. We are forming a line of battle, and each one is doing his part in clearing the field. I think the alienist has done his part, and done it well. I believe that the humane management of the insane has been developed to a degree that it could not have been developed by any other method. The time has now come for a change. That such a necessity is present, we all recognize, and with that portion of Dr. Punton's paper I am fully in accord. There is greater harmony between the alienist and neurologist, and this is as it should be. I believe that there is an opportunity for us to do most excellent work in dealing with acute cases of insanity in the general hospital. The percentage of such cases, however, is not very large; certainly not beyond 20, and I doubt if it would reach that. The number would be limited largely to cases of incipient insanity, associated with disorders of the eye or ear, or of the genital organs or gastro-intestinal tract. Such factors not infrequently act as the last straw in overturning a weakened brain from a condition of sanity to insanity, and it is in that class of cases that treatment in the general hospital would be most desirable. Another factor to be contended with is the family of the insane patient. Many families refuse to allow their relative to be immediately sent to an insane asylum, whereas if such a patient could be sent to a general hospital, the consent of the family could be readily obtained. In these cases of acute insanity, prompt treatment is the most important element. In connection with this subject I recently made a suggestion which I think would cover the ground very well. In every state we have a number of well-equipped insane asylums, each one covering a certain district. For example, in Michigan we have four such asylums. Why would it not be feasible to establish in each of these districts subsidiary establishments, under the charge of a competent trained nurse? These dispensaries, if you would so term them, could be established in a private house, or in connection with private sanitariums, and the patient could be kept there until the superintendent of the asylum in that section of the state could be notified. Then the latter or his assistant could go and investigate the case, in consultation with the physician who had charge of the patient. Then, if the case seems to be a suitable one for the general hospital, let it be sent there; if not, it can be sent to one of the asylums. It seems to me that such a plan would prove both feasible and satisfactory. In many of these districts there are alienists who could arrange the details regarding a temporary residence for these patients.

DR. G. W. MCCASKEY, Fort Wayne, Ind.—In Fort Wayne we have two fairly well-equipped rather small general hospitals, and our experience there with the treatment of cases of acute insanity has not been satisfactory. Some one in this discussion has said that 20 per cent. of the cases of acute insanity will be manageable in a general hospital. In my experience, it is even less than that. Furthermore, we can not foresee which of the cases belong to the 20 per cent. In one of our hospitals we have an entire floor, so far removed as possible from the other patients, reserved for the insane, and our experience has been such that I do not regard the plan as desirable.

DR. JOHN PUNTON—I think Dr. Weir Mitchell is entitled to much credit in being the originator of this modern method in reference to the better treatment of the insane. I agree with Dr. Dewey that every case of acute insanity is a law to itself, and it is almost impossible for any alienist to tell exactly what can be done for any case in the incipient stage. In reply to Dr. McCaskey, in my paper, I did not have in mind those cases that require bars to hold them, or those with suicidal tendencies. The ones I had in mind for general hospitals are the borderline cases.

---

# ARTHRITIS DEFORMANS.

## THE REPORT OF A SERIES OF ONE HUNDRED AND TEN CASES FROM THE JOHNS HOPKINS HOSPITAL.

(FROM THE CLINIC OF PROFESSOR OSLER.)

THOMAS McCRAE, M.D., M.R.C.P. (Lond.)
THE JOHNS HOPKINS HOSPITAL
BALTIMORE.

*(Concluded from page 96.)*

### GROUP IV. SPONDYLITIS.

As already said, the cases with spinal involvement fall into two groups, one with general, the other with local involvement. The former is readily diagnosed, the latter is certainly much more easily overlooked. These cases are usually considered to belong to the "osteoarthritic" group. The bony changes predominate, and especially new formation of bone. Certain writers hold that the osteoarthritic cases are quite distinct from the type previously spoken of as "rheumatoid" or those in which other than bony parts are especially involved. In certain of the cases of this series there seems no doubt of the *occurrence of both types in the same patient.* If this be true it goes far to prove that all the cases here grouped under the heading of arthritis deformans do belong to one disease which has various types. Not only were the two types of arthritis found in the one patient, but in some of those showing only osteoarthritic manifestations there was a history of attacks of acute polyarthritis exactly like those described under Group II, and from which the patient had recovered apparently completely. The histories are so characteristic that there seems little doubt of the nature of the old attacks.

There were 22 cases showing spinal involvement. In 13 of these there was spondylitis alone, while in 9 this was accompanied by symptoms in other joints; in other words, the lesions were of the polyarticular type, and these have been included in the analysis of Group II. In taking up the study of this group it is sometimes difficult to distinguish the symptoms from the spine and those from the other joints. In reference to the extent of spine involvement the cases were as follows:

| | Gen. inv. of spine | Local inv. of sp. |
|---|---|---|
| Spine only involved[8]...... | 6 | 7 |
| Spine and other joints[8]...... | 9 | 0 |

It is worthy of note that when the spinal involvement was associated with changes in other joints in no instance did we recognize involvement of a portion of the spine only. But, as said before, the confession is frankly made that only recently have we learned to diagnose the local form, and it is quite possible that instances of it have been overlooked. For the same reason the relative figures of these groups mean little as to their comparative frequency.

*Incidence.*—Of the 22 cases, 20 were males and 2 females. The striking preponderance of males is to be noted, especially as the other type is thought usually to occur much more frequently among females. All are white. The ages were as follows:

| | | | |
|---|---|---|---|
| 1 to 10...... | 0 | 41 to 50...... | 2 |
| 11 to 20...... | 1 | 51 to 60...... | 2 |
| 21 to 30...... | 6 | 61 to 70...... | 2 |
| 31 to 40...... | 9 | | |

*Complaint.*—This, in the majority, was of pain and stiffness in the back and legs. With this mention was often made of the crippling and general weakness. A few laid especial emphasis on the pain.

*Onset.*—The age of this was:

| | | | |
|---|---|---|---|
| 1 to 10...... | 2 | 41 to 50...... | 1 |
| 11 to 20...... | 10 | 51 to 60...... | 2 |
| 21 to 30...... | 4 | 61 to 70...... | 1 |
| 31 to 40...... | 2 | | |

Only 7 cases were admitted below the age of 30 years, but in 16 the onset was before 30. The onset in a few over the age of 50 is to be noted. The early age at onset in so many of the cases is striking.

The onset in the 13 spinal cases was gradual in 11 and sudden in 1, with one doubtful. In two of these there was a history of previous acute attacks of polyarthritis which subsided and left apparently no damage. These are exceedingly interesting. One may be noted briefly:

No. 61.—J. H., white, male, aged 45, was admitted complaining of stiffness of the back. There was a history of arthritis deformans in his family. From childhood he had at times some arthritis. With these attacks he was usually laid up, but never for very long. At 28 he had his first severe attack. This involved many joints and he was two months in bed. He recovered gradually and was well for seven years, when he had another attack with many joints involved, and the neck slightly. Three years and five years later there were subsequent attacks, in the last one his spine becoming stiff. On examination the joint changes were practically confined to the spine and hips.

---

[8] To prevent confusion it is convenient to refer to these two classes as the "spinal" and "mixed" cases.

In other cases there seemed little doubt of previous attacks of local spondylitis, from which they recovered completely, and were practically well for many years. There were seven with very suggestive histories of these previous attacks with apparent recovery at any rate from symptoms. These intervening periods varied from two to eighteen years. One can not help wondering if in some of these cases it is only some accidental occurrence—such as an attack of influenza—which determined another attack. If this be true it may be that many cases may recover at any rate from ordinary symptoms of the disease.

*General Features of the Spondylitis Cases.*—These are most characteristic in the cases of general involvement. The spine is fixed and the term "poker-back" is most expressive. In some the head is held forward and there is marked bowing of the upper spine, and all rotation in the cervical region is lost. The patient to look about has to move the whole body. There is much difficulty in stooping, and on an attempt to pick an object from the floor they have to crouch down without any bending of the spine. On examination, the natural curves of the spine are often lost and the bowing of the upper dorsal and cervical regions is at times marked.

In the type with local involvement the picture is not so striking. The area involved is usually the lower dorsal and lumbar regions. The patient may make complaint of the back—commonly of pain and stiffness, which he may refer to the spine or dorsal muscles—or very often, of pain in the legs. This latter is common, especially over the course of the sciatic nerve, and there is little doubt that many of the cases regarded as sciatica are really arthritis deformans of the lower spine. Too often the diagnosis of neurasthenia is made, and perhaps also lumbago—whatever that term may mean. These cases on ordinary examination show nothing. It is only on the attempt to have them do certain movements that the rigidity of the spine becomes evident. This can be demonstrated by having the patient stand with the feet together. The back should be visible. Then with the hips held, to prevent movement, the patient is asked to bend forward, backward and to the side. The restriction of free movement at once becomes evident, and it may be further shown by asking him to pick up an object from the floor. The marked interference with free movement between the vertebræ is very evident.

Certain curious features occur in some of the cases. There may be some alteration in the natural curves of the spine. Lateral curvature may be present. The upper part may be bowed with the convexity backward and the head held far forward. There may be marked prominence at the junction of the cervical and dorsal regions (1 case), or the lumbar curve may have disappeared (4 cases). There may be one prominent lumbar spine (1 case). The neck may only be partly ankylosed. Bony thickening may sometimes be felt about the neck vertebræ (2 cases). In 1 case the neck was rigidly fixed to one side. Occasionally the back muscles—especially in the lumbar region—may be very rigid or they may show wasting.

In some instances the hip joints are involved and there is restriction of movement there. In others, the symptoms are all referred to one leg, and the patient may systematically "save" it, and so usually walk on the toe or with the knee slightly flexed. Such cases are often mistaken for tuberculous hip disease. Some of these patients may limp very markedly.

*Emaciation.*—This is often marked, and was especially so in our group of mixed cases. With this there may be marked pallor, although this is usually more marked than the actual anemia. The local wasting is often very extensive. The muscles of the back, but especially those of the buttocks and legs, suffer. This does not seem to be always symmetrical. One side of the spine at times may be more involved, and the wasting be greater also on that side.

*Reflexes.*—These are usually increased in the legs, both the knee jerks and the tendo Achillis reflex. With this increase in the legs, the arm reflexes in the local spinal cases are usually normal. In only one case was a diminished knee jerk noted. The cremasteric reflex was increased in 2 cases and an ankle clonus was obtained once. In 1 case with signs more on one side the reflexes, including the cremasteric, were all increased on this side and normal on the other.

*Temperature.*—Of the 13 spinal cases in 4 this was normal, in 5 it averaged 99 F., and in 2 it varied from 99 F. to 100 F. Of the mixed cases 3 had a normal temperature; these averaged 99 F.; 2 varied from 99 to 100 F.

*Pulse.*—In the spinal cases, 5 were normal (70 to 80 F.), 4 were between 80 and 90 F., and 3 between 90 and 100 F.

*Blood.*—In the spinal cases there are counts in 4 with an average hemoglobin percentage of 76; red cells, 5,205,000, and leucocytes, 7,800. The leucocyte count was over 10,000 in only one instance (11,300). In 4 mixed cases the averages were: Hemoglobin, 69 per cent.; red cells, 4,980,000, and leucocytes, 6,300. These findings are practically negative. The differential counts were normal also in both forms.

*Tuberculin.*—This was given in all the spinal cases and always with a negative result. It is a great help in the matter of diagnosis.

*Radiographs.*—These show a very characteristic condition. In all but probably the very early cases, definite deposits of new bone can be made out.

### PATHOLOGY.

In this osteoarthritic group we have usually a marked overgrowth of bone. There is proliferation of the articular cartilage and later ossification of these outgrowths. Certain other structures may also be involved in the bony change, such as the ligaments or fibrous tissue. These bony structures usually show little alteration in their histologic structure from ordinary bone. There is marked hypertrophy of bone in contradistinction to the type previously described where atrophy predominates.

In the spine the process frequently begins on the anterior aspects of the bodies of the vertebræ and extends along the ligaments. With this there is deposit of new bone. This may mean a more or less continuous bridge of bone, and in the radiographs of such cases the bony deposits can readily be seen between the bodies of the vertebræ. These may be on one or both sides, but in early stages are often unilateral. The subsequent course is very variable. The process may advance only slightly and there be comparatively little change. If the process be very active the intervertebral cartilages may be replaced by bone before any absorption occurs. In such cases we have the typical "poker-spine," simply one continuous bony column. Should there be gradual atrophy of the cartilages without replacement by bone, gradual curvature will result. This is seen very markedly at times in old men, who make little complaint of any symptoms. Should such a process occur more on one side we get a lateral curvature. All these various processes may occur throughout the whole spine or be limited to certain regions, most often the lower dorsal and lumbar.

These changes may also occur in the posterior portions of the vertebræ and the lateral or spinous processes be involved. The articulations may be involved both between the vertebræ themselves and with the ribs. This latter gives an interesting condition, namely, almost complete absence of any movement of the ribs and a practical loss of all costal breathing. This was very marked in some of the cases of this series. There may even be severe pain complained of—in the acute stages—when the patient tries to take a long breath, as was well instanced in one of our cases. Should the formation of bone encroach on the foramina it is readily seen why pain referred to the distribution of the nerves passing through them is so common. This, too, may be on one side only, with unilateral involvement.

It is readily seen from the lesions why the symptoms are so varied. The stiffness is, of course, due to the local conditions. Pain may be in the back itself, but is very frequently referred to the areas of distribution of the nerves involved.

### DIAGNOSIS.

As in the acute polyarticular form, the knowledge of the condition is an essential to its recognition. The cases of general involvement are so characteristic that a glance is usually enough to give the diagnosis. There is no need to dwell on them. But with the local forms the story is different. We have long been blind to what was before our eyes very frequently. To Dr. Goldthwait[9] of Boston much of the credit of drawing attention in this country to these conditions is due.

The symptoms complained of most commonly are stiffness, interference with motion, pain and muscular weakness. It may be that many of the indefinite pains complained of in the back, especially in the morning on waking, are due to this condition. Lumbago, while probably rheumatic or gouty in some, is perhaps at times due to this. Many of the cases of so-called "sciatica" are caused by arthritis of the spine, and also instances of obscure pains in the legs and about the body.

There is no intention of suggesting that every case of pain in the back or of sciatica is due to spondylitis, but it is suggested that in every such case it is most important to examine the back. Some cases otherwise regarded as neurasthenia with complaint of pain in the back (which is, unfortunately, only too common a combination), will be found to have local arthritis of the spine. Patients complaining of sciatica may have the same condition.

Of the methods of diagnosis first comes the examination of the spine. The patient should be completely stripped, or down to the hips at least. In the majority of cases little is to be made out. There may be some curvature, or a projecting spine, or more commonly an obliteration of the lumbar curve. There may be wasting of the dorsal muscles, or in the gluteal region, or of one or both legs. In some the attitude is suggestive. They stand with one leg a little flexed and "favor" that side. These results may be only suggestive. Next comes the investigation of the mobility of the spine. With the legs straight, the patient is asked to bend forward and touch the floor, bend back and to each side. Any limitation of motion is very readily recognized. This may be equally marked in all directions, or only in one, although usually at least two are combined. He may bend forward but a very short distance and to one side much less than the other, or lateral movement to one side only may be much restricted. These variations are very readily understood in view of the pathologic anatomy. These movements may cause pain, either local or referred. An attempt to bend to the right may cause the same pain in the leg of which the patient complains. The attitude on attempting to pick up an object on the floor is often characteristic. With this the sensation should be tested; areas of altered conditions are important. The reflexes are usually increased.

The diagnosis may be fairly clear from this examination, but there are two important aids, namely, tuberculin and the *x*-ray picture. The use of tuberculin excludes the most common source of difficulty, although tuberculous disease of the spine rarely gives the same disease picture as spondylitis. In some instances there is marked involvement of the hip joints with the spondylitis, and this may have led to a suspicion of tuberculous hip-joint disease. The radiograph, if it shows anything, is usually characteristic. The deposits of bone usually appear as shadows between the bodies of the vertebræ. In early cases, of course, little may be seen, and in very fat patients it may be difficult to get a clear plate.

Should the diagnosis not be certain with any of these methods, one help remains—the therapeutic test. Put a light plaster jacket on the patient, which should extend from the axillæ to the level of the trochanter, and if there be spondylitis there should be marked improvement in the symptoms in a few days. This is especially useful in the cases with sciatica.

### TREATMENT.

As in the other type, attention should be given to the general nutrition. The same rules for the care of the general health, fresh air, sunlight, nutritious diet and tonics (the syrup of the iodid of iron, arsenic, cod-liver oil, etc.), should be carried out. With these, massage, bathing, hot air and baking to a limited extent, may all be used. Locally, the great object to be attained is rest. This can not be done by keeping the patient in bed, unless the back be well supported, and this is difficult to accomplish properly. Some kind of jacket is more suitable. Perhaps the best plan is to put on a plaster jacket for two to four weeks, and then a strong enough leather one to serve the purpose. With the parts at rest, the pain lessens and the muscular irritability diminishes. In the cases with much curvature the muscular contraction is often largely responsible, and a month with the jacket may almost completely correct this. The jacket should be put on with the patient standing as straight as possible, but no force should be used. If there be deformity, the jacket will often gradually correct this, and a second one can be put on in two weeks. The jacket or support should be worn until the process is at a standstill, and later some lighter apparatus may be substituted. In such cases, after the condition is improved, every care should be taken to keep the general health as good as possible to lessen the chances of subsequent attacks.

In the cases with general involvement the damage is done. Some form of light jacket may give relief, but the general health is the most important thing we can influence.

---

[9] Boston Med. and Surg. Jour., vol. cxli, 1899, and vol. cxlvi, 1902.

The early diagnosis is the most important consideration in treatment. But in the prognosis one has to keep in mind that the disease may advance steadily despite all treatment, and that the most that can be done is palliative.

### CONCLUSIONS.

The points to which special attention is directed are:

1. The frequency of the occurrence of acute polyarthritis in arthritis deformans and the danger of mistaking this for acute rheumatism.
2. The importance of the recognition of the spinal forms of the disease, especially the local involvement.
3. That in arthritis deformans we have an obscure disease of considerable frequency worthy of study, especially from the etiologic aspect.

### DISCUSSION.

Dr. James J. Walsh, New York—There is nothing more used to give lasting reputation to quacks than the treatment of chronic rheumatism. If the disease be examined very carefully it really resolves itself into a series of affections not rheumatic at all, nor does it have any relationship to articular rheumatism. The latter runs a definite course and is cured completely and no marks are left in the joints at all. Rheumatic arthritis considered as an acute disorder which leaves marks in the joints, is quite another affair. The term "rheumatism" is likely to cover many mistakes in diagnosis, and many errors and negligences. There are three things that are mentioned in the newspapers, catarrh, rheumatism and gout, and curiously enough the three words mean exactly the same thing; etymologically, they mean "to flow," or "to have excessive secretion." Few recognize the fact that acute rheumatism never becomes chronic rheumatism. Rheumatoid arthritis is another disease especially in this country, and is not affected by the remedies commonly used in the treatment of rheumatism. It is to be hoped that in the beginning of the twentieth century something will be done to clear up the large group of cases called "chronic rheumatism" and bring a little order out of chaos. The word rheumatism has been abused to an enormous extent, and so long as practitioners are satisfied with this for diagnosis, rational therapeutics is impossible.

Dr. J. T. Moore, Galveston, Texas—During the past four or five years that I have been connected with the department of medicine in the University of Texas, I have been looking for just such cases as Dr. McCrae has reported to us. Two years prior to this I was demonstrating anatomy, and since then I have tried to keep up my connection with the department of anatomy. We have been astonished at the large number of cases we have had in the dissecting room with this disease, the changes occurring in the joints, and yet not recognized prior to death. Some of these cases were diagnosed as chronic articular rheumatism, and some were not diagnosed as rheumatism at all; yet we found various changes in the joints when they were examined in the dissecting room. As physicians we should enter more on the investigation of this disease. It is evident that most of these cases are not due to chronic rheumatism, although so often diagnosed as such, but to arthritis deformans. I know of one case in particular suffering from intense pains in the legs. I told the man that he had sciatica; then I afterward told him he probably had chronic rheumatism; but there is little doubt in my mind that if he were brought to the postmortem table some changes might be made out in the vertebræ, showing it to be arthritis deformans.

Dr. C. E. Skinner, New Haven, Conn.—The victims of arthritis deformans are numerous enough and miserable enough to justify a demand on their part that we put ourselves in a position to do something for their relief, and a correct and early diagnosis is the first and most important step in this direction. The majority of physicians confound this disease with others of an entirely different nature, prominent among which may be mentioned rheumatism, neuritis and gout. Rheumatism is comparatively easy to cure under modern therapeutic methods, neuritis is considerably more resistant than rheumatism, and arthritis deformans presents a very difficult problem under any conditions, and especially so when a correct diagnosis and the inauguration of a proper line of treatment have been delayed long enough for profound pathologic changes to have taken place in the joint structures. The condition of some of these victims of failure to recognize the ailment early is pitiable, indeed, from extensive ankylosis of the large joints, which condition complicates the therapeutic problem to a marked and sometimes totally unmanageable degree. The importance of correct and early diagnosis, moreover, is well brought out by Dr. McCrae when he says that arthritis deformans is usually made worse by antirheumatic or antineuritic therapeusis. This has also been my experience. I know that it is almost, if not quite, impossible to differentiate some cases of arthritis deformans in the early stages from acute articular rheumatism, but in the majority familiarity with the clinical aspects of the subject and a proper degree of care and thoroughness in the study of the individual case will render possible a positive determination as to the nature of the pathology present. Then an appropriate line of treatment can be adopted at once and the patient will be saved from much future misery. More work should be devoted to the diagnosis of this disease, and when this is generally appreciated it will be better for our patients, and they will have less just cause for complaint.

Dr. Thomas McCrae, Baltimore—There are many aspects of the disease, and there were only two or three that I hoped to emphasize in my paper. I said nothing regarding the etiology; that is a doubtful matter, although the evidence, to my mind, points toward infection with one specific organism or several. The nervous symptoms may be explained by the fact that they are largely due to toxins.

With regard to early diagnosis, the importance of that is very great, and may give us the possibility of preventing later changes.

In regard to the treatment there are certain general principles which should be considered in both types of the disease. Good nutrition, sunlight, fresh air, and good food are essential. Patients who have not obtained those will be more likely to have subsequent attacks. The syrup of the iodid of iron is good, given alone or alternating with arsenic. This should be continued not for months but for years. Massage is usually helpful. Baths are of doubtful utility in many cases. When we consider the local treatment we should think of the two groups. In the osteo-arthritic form rest is very essential, but in the rheumatoid group exercise is essential. In the spinal cases the patients should be placed at rest for a time. In the rheumatoid cases if the patients are kept in bed there may be contractures, muscular atrophy and the joint changes may progress. In the treatment of such cases two things are very essential, viz., patience and perseverance, both in the patient and in the physician.

---

Malpractice Defined.—A physician or surgeon is liable to be sued for malpractice in treating a patient: 1. When he does not possess ordinary skill, science, and information; or, 2, when he does not use reasonable and ordinary care and diligence in applying his knowledge and exercising his skill; or, 3, when he does not use a reasonable and ordinary degree of skill and knowledge in treating the patient; or, 4, when he does not exercise ordinary care and diligence in attending and treating the patient; or 5, when he fails to give proper instructions to the patient as to the care of himself; or, 6, when he fails to use ordinary care and diligence in determining the frequency of his visits and the cessation of the same; or, 7, when he fails to follow the established modes of practice of his particular school and the advancement in it, and injury results to the patient. And all this whether or not he is to receive compensation.—*Medicolegal Bulletin.*

# THE NECESSITY FOR MEDICAL TRUSTEESHIP AND FOR A CENTRAL LABORATORY IN STATE MEDICAL INSTITUTIONS.*

A. P. OHLMACHER, M.D.
Superintendent of the Ohio Hospital for Epileptics.
GALLIPOLIS, OHIO.

The contact between the medical profession and the state medical institutions is not close enough. This is true everywhere in the United States. It is particularly true in Ohio. Among the thirty-five trustees governing the eight principal state hospitals in Ohio there are at present but three medical men as members of the boards. To be sure, the medical profession has a representative as local executive head of these hospitals and a number of medical men are employed in the capacity of assistant physicians. But in the real governing body, the one vested with final authority in all important matters, physicians are conspicuous by their absence. Such a condition is bad both for our profession and for the state institutions. The medical profession has much to gain from the proper administration of the state hospitals, and particularly in so far as it concerns the use of the vast material of these hospitals for the advancement of medical knowledge. The state hospitals are much in need of the support that would be afforded by active, broad-minded medical representation on the boards of trustees, for it is a fact generally conceded that the strictly medical work, and particularly the scientific work in these institutions, is far below what it should be.

As concerns the individual institutions, this state of affairs could be remedied by placing on each managing board at least one progressive medical man who could educate his fellow-trustees to the needs of the institution, and who, with his colleagues on the board, could secure the respectful attention of the state authorities and of the legislature. It would be needful, of course, to have in each institution an executive head who would be in warm sympathy with the ideas of medical improvement, and who would work in conjunction with the medical trustee.

It seems to me that a great and powerful organization that is working for the most unselfish of purposes—the advancement of human knowledge and the alleviation of human suffering—such as our medical profession is getting to be, should assert its right to participate in the management of the immense state medical institutions which are, after all, but creatures of our profession, and which each and all contain a vast storehouse of knowledge, for the most part now uncultivated. Our profession should declare in unmistakable terms that mere questions of shelter, food, and raiment are not the most important considerations in the conduct of these institutions; they should be, in reality, more than great state-endowed hotels for the insane and epileptic. Our obligations to humanity demand that as scientific medical men we should enter these hospitals and use their material for study, the aim of which should be the solving of the problems that surround the causation, prevention and treatment, not alone of insanity and epilepsy, but of other diseases such as are invariably found among an assemblage of eight thousand ailing human beings like those now filling the Ohio state hospitals. I predict that success would attend the effort were the now well-organized Ohio State Medical Association to make a formal request for medical representation on the governing boards of the state medical institutions, and I believe it would be possible for the association to secure favorable attention to the candidates whom it might, because of their peculiar qualifications, suggest for these positions.

By bringing into each individual institution a new impetus for scientific work through the efforts of an active medical trustee, much good could be accomplished. Funds could readily be found for a better equipment for medical, surgical and scientific work, and a high grade of physicians could be attracted to the service of the state. By this means a more intimate touch between the medical profession and the state institutions could be secured.

There is another plan that will bring the medical profession of the state at large in sympathetic relationship with the state hospitals, and that is by the establishment of a central pathologic institute as part of the state hospitals' system. The idea is certainly not original, for in the first place at least one state, New York, has already established and placed in successful operation a central pathologic institute; and the project is under way in Michigan, and is being actively discussed in Iowa and elsewhere. But there is a phase of the plan outlined for our state which is unique, and I believe important, and that is the one which proposes that the initiative in the movement looking to the establishment of a central laboratory be taken by the Ohio State Medical Association and that the preponderance of power in the management of its affairs be left in the hands of representatives from the association. To a considerable extent this would make the central laboratory a creature of the state association and the active interest of the medical profession would be retained.

In order further to make the central laboratory of the state medical institutions beneficial to the profession as a whole, it has been suggested that the collection of gross pathologic specimens which naturally would soon be assembled be held open to the profession of the state to become the pathologic exhibit of the state association. Further it would be desirable to have tables in the institute reserved for the use of members of the state association properly qualified to prosecute original research along such lines as would come within the scope of a pathologic institute.

Most of the members of the Ninth Councilor District assembled here to-day are doubtless aware that the project of a state pathologic institute was indorsed by the Ohio State Medical Association at its last annual meeting; that resolutions commending the plan were adopted, and a committee appointed to forward the movement. It was planned to bring the project to the attention of the general assembly which soon convenes. As a member of the Committee on the State Pathologic Institute I am prepared to say that plans have been formulated for an active campaign during the coming session of the legislature. The committee, however, needs the hearty support of every member of the association who can reach a state legislator, and I bespeak the active co-operation of the members of the Ninth Councilor District in our propaganda.

Given a laboratory located in Columbus, sheltered from political interference by the Ohio State University, drawing its material from the several state medical institutions in Columbus and from those scattered throughout the state, properly equipped and judiciously directed, the medical profession of Ohio would have a product to which it could point with pride, and the state an addition to its medical institutions whose benefits would ultimately reach all its citizens.

---

* Address before the first meeting of the Ninth Councilor District Medical Society, Jackson, Ohio.

# A PLEA FOR UNIFICATION AND UNIFORM ORGANIZATION.

J. N. McCORMACK, M.D.
Chairman of the Committee on Organization of the American Medical Association.
BOWLING GREEN, KY.

*To the Medical Profession of the State of New York:*

After correspondence on the subject with members of the Joint Conference Committee and others, more especially on the society side, I have been requested, as chairman of the committee which has had this work in charge from its inception, to prepare for publication an explanation of the plan of organization for state and county societies which has been so generally adopted in the last two or three years. As the plan was prepared and is recommended for universal adoption, is already in satisfactory operation in 32 states and in over 1,500 counties, and is likely to be adopted in nearly all of the other states as soon as their annual meetings occur, as the subject is one of interest at this time to every member and well-wisher of our profession, and more especially as the preparation of the plan for general adoption makes my committee as responsible to you for anything wrong in it as though we were members of your county and state societies, it seems entirely proper that the request should be complied with.

An attempt will be made to place beyond question the truth of the following propositions:

1. That existing professional conditions and estrangements are useless and senseless; that they are hurtful almost beyond calculation to both the profession and the public welfare, and that they are remediable.

2. That the plan of organization is based on our system of civil government; that it was prepared with much care and unselfishness, and that it contains nothing untried, experimental or impracticable.

3. That the county society is not only the unit of the organization, but the source of all authority and power in both the state and national bodies through a representative delegate system, and it is also the only portal of entry to the entire society system.

4. That coincident membership has been an old and perfectly satisfactory method in many states, is essential to complete organization, and that it is just and right. It would be as unfair to permit a physician to become a member of his county society and enjoy all the benefits arising from the labors of the state society, as to permit one to become a citizen of Ithaca or Troy without becoming a citizen of the State of New York and bearing the burdens and responsibilities of the same.

5. That amendment of any part of the plan is purposely made easy and is controlled by delegates from, and responsible alone to, the county societies.

6. That the time has come for unification, and that, while union under a defective plan, which the joint body could modify and improve for the common good, would be far preferable to a continuation of existing conditions, the one now proposed has been found excellent and practical after full trial in other states, and having been prepared away from New York conten- and controversies, it offers a basis for compromise alike to both factions and to neutrals.

to establish these propositions clearly and a brief history of this reorganization movement is necessary. From the very outset the magnitude of our task grew on us. Although in name medical societies—city, district, state and national—existed without number, and medical machinery and high-sounding official titles were provided sufficient for the civilized world, membership in most of them was small and little more than nominal, and, outside of a few states and localities, the profession was so torn with dissensions that it was in chronic disgrace in its own and in public estimation, and in a large measure robbed of its power, by legislation or otherwise, to help either itself or the public, for whose benefit it was supposed to exist. Into a profession already so overcrowded that there was less room and remuneration for the average physician than for clerks and skilled laborers, commercial medical colleges were annually turning loose thousands of new graduates, many poorly equipped for intelligent modern practice, and practically all of them without an hour's training in professional conduct, business methods, the importance of society membership, in which all should have been drilled with the care due to subjects to become of so much importance as soon as they come to serve the public and face the problem of earning an honorable livelihood.

Largely as a result of such lack of training, we found that of the 120,000 registered physicians in this country, only about 30,000—one in four—had ever been members of any kind of society, local, state or national. Most cities were little better organized than the country districts, a large submerged element being often found within an easy walk of imposing medical and post graduate schools, libraries and hospitals, who had long lost hope of advancement, looked on their profession only as a doubtful means of support, while those in the higher ranks wrangled and slandered each other and brought odium on all, and Eddyism and other forms of bald quackery took the cream of a patronage which a united, self-respecting and honored profession would have deserved and received.

It was soon found, however, that these conditions, deplorable alike to the profession and public, were not universal. In Alabama, for instance, under a model plan of organization and resulting united profession, with over 1,500 of the 1,700 physicians members of the county and state societies, medical opinion was sought for the guidance of law-makers, executives and courts, the profession was honored and independent, and quackery was unknown. Kentucky, striving for the same ends under less perfect methods, had had no itinerant or advertising doctor within her borders for ten years, and the profession was aspiring to its rightful place as a directing force in public affairs. In a dozen cities also, usually of the lesser rank in population, under similar influences, harmony, co-operation and measurable prosperity prevailed and was increasing.

Inquiry soon demonstrated that the personnel of the profession was much the same everywhere, and the difference in the conditions found were apparently entirely due to difference in methods of organization. After all proper allowance for personal equation in rulers, governments are liberal or despotic as determined by their organic laws, and probably quite as much as with a nation, the constitution and by-laws of a medical society will set the compass and shape the policy which will largely determine the future for both itself and its individual members.

Influenced by such belief and considerations, my committee began its work four years ago by grouping those provisions for state and local societies which had resulted in the most effective organizations, and with great care made our first draft of a constitution and by-laws for submission to, and discussion by, conferences of leading men in the various medical centers where there was a reasonable degree of harmony. Later, the improved draft was published in the medical press and in pamphlet form and given the widest possible publicity. As we were performing an important, unselfish and gratuitous public service for the common good, advice and frank criticism were cordially asked from all, and these came freely and helpfully, especially from the better organized states and cities.

With such assistance, and in the light of such criticism, keeping always in mind that the plan should be democratic and conform to our methods of civil government, with local self-government by the county societies as the central idea, a simple but comprehensive system was gradually evolved, almost ideal in its outline and possibilities, which, after full trial under the most diverse professional conditions, has proven entirely practical, being so flexible that it could be adapted to the Cook County Medical Society at Chicago, with 1,800 members, as easily as it could to sparsely settled counties in North Carolina or California, with 10 members. Under its operations in one year in Michigan the membership increased from 560 to 2,100; in Kentucky, from 390 to 1,600; in Tennessee, from 300 to over 1,000; in Missouri, from 400 to 1,500; in Arkansas, from 190 to 703, and in like proportion in every other state adopting it.

It is a thoroughly democratic and American plan, using those much-abused terms in their broadest and best sense. As has been said, the county society is made the broad foundation and source of authority for everything, as well as the portal of entry to both the state and national bodies. If a physician stands well enough at home to secure membership in his county society, he is eligible for membership and for any position of honor or trust in the state and national bodies, and if he loses membership at home, subject to the right of appeal, he loses privileges everywhere.

The house of delegates, the legislative and business body of the state society, like the general assembly of a state, is composed of representatives from the county and district societies, and such delegates are freed from political influence so far as possible by making them ineligible for any of the offices within their gift, and they are responsible alone to the constituencies electing them. As they are in session but two or three days, in order to make the transaction of any business possible, unlike senators and representatives, they sit as one body. This gives a body small enough for deliberative work, and yet gives county societies remote from the place of meeting, and all others, an equal and only an equal voice, in all business affairs if only the delegates are in attendance.

Carrying out the same principle of local self-government, this house of delegates, made up directly from county and district societies, elects from the general membership the delegates who, in turn, compose the legislative body of the American Medical Association. As in the house of delegates of state societies, this being a small body, with its members carefully selected and made ineligible for any other position, with the terms of half the members expiring each year so as always to have men of experience in it, and which can remain in session, if necessary, after the general meeting adjourns, it was hoped to provide a body in which the interest of the profession and of scientific medicine might be considered and promoted in the broadest way.

The question of coincident membership in county and state societies is one which should require little explanation in New York. It has given satisfaction in the association, and has, of course, been under the observation of the society people. You have also had ample opportunity to observe the results of it for years in the neighboring states of New Jersey and Connecticut, where it has been in operation for years. It has been long the practice in Alabama, with the result that about 90 per cent. of the profession are permanent members, as well as in Massachusetts, Pennsylvania and Indiana, and recently in a total of thirty-two states. It is only one feature of the work, but it is so important that any complete or systematic organization of the profession is impossible without it. Besides, the justice of it is beyond question. It would be as obviously unfair to permit one to join his county society and enjoy all the benefits of the state society arising from its legislative, educational and other expensive and responsible labors, without assisting in its support, as it would be to permit a man, if one could be found so foolish and selfish as to ask it, to become a citizen of Buffalo, Syracuse or Rochester and enjoy all the benefits and protection of the state government without becoming a citizen of New York.

It is true that in nearly every state where this plan of organization has been proposed, as was natural and to be expected, academic and purely theoretic objections have been made to some feature of it, usually to the council, the house of delegates or to coincident membership. Such objection has always been made in advance of a trial of them, and they have been confined almost entirely to states which have been practically without organization heretofore. Conditions in Iowa illustrate this point well. The county society at Dubuque, which has reorganized and applied for a charter within the last ten days, raised many such theoretical objections to the plan before they had tried it, while 88 counties in the same state, organized under it, and realizing its practical benefits, are loud in praise of the very provisions to which their worthy neighbor at first objected. It is a source of much encouragement that this has been the experience of over 1,500 counties which have reorganized.

It would be pleasant to comment on each provision of the plan in detail if space permitted. Suffice to say, that it was intended only as the foundation and framework for a broad and comprehensive system to be recommended for universal adoption; that nothing was included except for what appeared the best of reasons, and that it is susceptible to infinite elaboration and improvement in detail as the profession of any state or county develops under the catholic and co-operative spirit which it inculcates, and which is so much to be desired.

Attention is called to the fact also, that much contained in the by-laws, where a wide departure is made from the brevity and compactness of expression adhered to in the constitution, is suggestive and educational in character, much of which would not be necesssary if such an organization as is contemplated was already in existence. We thought it as important, under existing conditions of discord and demoralization, to furnish incentives to this work, to give practical and detailed information as to how it was to be done, and to put the reasons for it all within the easy reach of those whose duty it would be to discuss the subject and do the work, as to furnish the framework of which, as the result of years of devoted labor, they were to make a complete edifice occupied by a united and harmonious, or at least a decently co-operative and self-respecting profession. For many reasons, too, amendment to the plan is purposely made easy. If, after trial in any state, anything is found obsolete or impracticable, it can be easily eliminated or replaced by something better adapted to existing needs, by the house of delegates, subject to instructions from the county societies, at any regular meeting, after such an amendment has lain on the table for one day.

Unification in New York has been so long the dream and hope of its own profession, as well as that of the entire country, that now, when this seems about to be realized, it may be that a majority of you will consider mere methods and details of organization important only insofar as they are likely to hasten or delay the union. In part, this view of the matter is both natural and correct. A cordial union under a defective plan, which could be modified and improved to meet the needs of the joint body, when there would be unity of purpose and interest for the common good, would certainly be far better than to perpetuate the two bodies, even with model organizations for both, with the strife, discord and loss of public respect inseparable from such conditions anywhere.

Still, if it can be shown, as the writer believes will appear on the most critical investigation of what is now proposed, that it furnishes ready to your hands a plan of organization to which you may build and add with confidence in the results, and which will at the same time hasten unification by furnishing a basis of compromise between factions so long divided that suspicion and jealousy have become so much mental habits that neither will be willing to accept what the other proposes, it should, and I am sure will, receive respectful consideration at your hands.

In the era of good feeling and enthusiasm which must follow unification, under such a broad, liberal and comprehensive plan, which would give an equal voice and power to the individual physician in every county, organization should and would make rapid strides, and the possibilities opened up to your profession, and then to your people, would be almost beyond conception. In the face of such possibilities, standing on the threshold of such accomplishments, petty prejudices and personal interests appear so insignificant that they should find no place in large minds.

Then, as New York would be in perfect alignment with her sister states, with proper education and effort, everything desirable would, in time, be brought within reach of the united profession of the entire Union. The complex and difficult problems before the profession of this country incident to our unprecedented advance in population and civilization, and which must be solved by it, if they are to be solved, will tax its highest intelligence and energies at its best. Provision can then be made for continuous scientific research, and for systematic collective investigation into the causes and prevention of disease on the large, generous lines demanded by the vast interests involved. The vexed problem of medical education can then be taken up with confidence and justly and wisely solved. Reciprocity in licensure and membership between states can then be discussed from the standpoint of the common good and settled on some equitable basis. Constructive statesmanship can be substituted for the narrow, time-serving political methods of the present in municipal, state and national public-health affairs, and our great profession—great even now in spite of its divisions—united, elevated and ennobled, would come to occupy its rightful place as one of the greatest of modern forces for the guidance and protection of our people. It would be an honor, even to New York, to lead in a reform promising such results, and to set an example in complete organization, which less favored and weaker states would imitate with both pride and profit. First of all, leading to all, and above all, in the words of your victorious commander, greater in magnanimity even than in war, "Let us have peace."

---

## THE HISTORY AND ETIOLOGY OF "MIGRAINE."

GEORGE M. GOULD, M.D.
PHILADELPHIA.

The word *migraine* (*megrim, the megrims,* etc.) is the vulgarization of a misnaming and meaningless term for a malobserved and trivial symptom, which in the majority of cases is not present, of a widely prevalent and ingravescent disease, with indescribable symptoms, which wrecks life and morbidizes the mind, the etiology and pathology of which are unknown, the location or organs affected being also unknown, and of which no treatment avails.

The term is a corruption of the Greek 'Ημικρανία and the Latin, *Hemicranion* or *Hemicrania,* taken to mean a pain in one side of the head. The word is, of course, an absurdity, because it denotes not pain, but only half-headedness, the idea of pain having no part in the construction of the word. One may perhaps speculate in vain as to the reasons of the Greeks for making half-headedness a synonym of pain in or on one side of the head. The fact itself seems to imply that when the word was born there must have been many patients who were so greatly tormented with this unilateral pain of the head that it was at once understood when such a patient was spoken of as "half-header"—"the man (or, more probably, woman) with half a head." The term was used in this way by Hippocrates, Galen and other Greek physicians with the same indiscrimination to express all headache, until Alexander Trallianus in the sixth century recognized that there were two forms of headache, and he urged that hemicrania or migraine was that which resulted from gastric disease or suffering.

In the seventeenth century the kinds of headache began to multiply, and they have continued to do so until now they are almost innumerable. The more coolheaded, at least not half-headed, English of one or two hundred years ago, began to recognize that "half-head" did not imply pain, and that pains in the head were by no means one-sided. Migraine, they saw, was not etymologically a pain, and the pain that existed in patients was not migrainous. Thence began the use of the good old English word *head-ach.* In his excellent dictionary published in 1809, Parr refers migraine or megrim to *cephalalgia,* and treats of the whole subject of headache, migrainous or not, under this heading. It was a sensible thing to do. It followed that the headache accompanied by gastric disorder, nausea, vomiting, indigestion, etc., naturally and rightly received the name *sickhead-ach,* or as we now say, *sickheadache.* With so-called "scientific" medicine (which in so far as pertains to this disease is absolutely as unscientific as was that of classic or medieval times), there was a relapse to the absurd term migraine, and under that caption are now published hundreds of crudite monographs that throw little or no light of knowledge on the ludicrous tangle. The word is now applied to a symptom-complex of infinite variability to indicate a very common and violent disease, the cause of which is wholly unknown, and for which there is no cure.

The old term, "sun-pain," applied to the disease is of illuminative significance. It was so called because it lasted, in the olden times when the theory was formed, only so long as the sun shone, and ceased with darkness. Now, in those times all reading and writing was done by daylight; at night, the absence of artificial lights compelled cessation of literary, sewing, and handcraft occupations. With this ocular rest, as always, came immediate relief of the ocular reflexes called "head-ach" and "megrim."

*In Literature and in History,* the disease itself has played a tremendous rôle, and it is not surprising that writers should have busied themselves with it. To attempt any culling or epitome of the literary allusions to headache would fill volumes. There is hardly an observant author who does not give intimations of the fact that must have been either before his eyes, or in them, or behind them, almost every day in his life. For as a source of pain and suffering, as a molder or destroyer of literature, as well as of lives, headache has been, I doubt not, one of the greatest producers of evil. In any city, village or community of the civilized world, if one will ask any woman, and every second man, he will be told that all know of relatives, friends, and even whole families, constantly suffering from headache, sickheadache and other eyestrain affections. Willis, an ancient writer, already said of this affection:

> There is none but is sometimes obnoxious, so that it has become a proverb as a sign of a most rare and admirable thing "that his head did never ake."

Other diseases, the plagues, poxes and punishments of evil and unsanitary living, came and went, but headache always remained with men and women, at least since civilization came to them.

An old English chronicler speaks of one:

> "A fervent mygreyn was in the right syde of hurr hedde."

Other references are:

> "Heyera hermetis purgeth the hemicran."—*Lloyd, Treas. Health,* 1585.
>
> "Oyle of fystikes healeth the hemicrane and watchynges."—*Do.*
>
> "Here hence springs the head-ache . . . which last we call the Hemicrany or Megrim, possessing but the one side of the head."—*Vaughan,* 1600.
>
> "The bones help the Hemicrania."—Lovell, 1661.
>
> "Subject to the sickness called Megrim or Hemicrain."—*Blount,* 1656.

The opinion of the writer in that monument of French erudition—Larousse's *Grand Dictionnaire Universel*—is plainly implied in the opening sentence of the article on *Migraine:* "The disease which physicians have baptised with the fine name of Hemicrania, without, for all that, feeling themselves under any obligation to cure it." "The shame of medicine," the writer calls it, later.

Méry says that Migraine is "a wonderful invention which will last until there are no more women."

Samuel Johnson quotes Bacon's Natural History, which says that "in every megrim or vertigo there is an obtenebration joined with a semblance of turning around." Both of these chief symptoms, it should be noted, are visual.

Pope wrote:

> There, screened in shades from day's detested glare,
> Spleen sighs forever on her pensive bed,
> Pain at her side and megrim at her head.

"The sole thing that brings me relief," still say many patients, "is absolute darkness."

In his "Physiology of Marriage," the Frenchman, Balzac, best fitted to give expression to the national opinion, gives a vivid picture of the disease as illustrated in upper-class families. It is always the wife who is afflicted. He pictures it as the queen of diseases, the most pleasant and at the same time the most terrible weapon which a woman can use against the husband. "I have the migraine," ends all controversy. But while ridiculing the disease as a makeshift of these cunning ones to deceive, Balzac gives an admirable description of the attack, and lets us see that the assumed disease is certainly an imitation of the real, and perhaps the idea of trickery was read into the real experience by the husbands and the romancer. Her book, he says of the patient, is at her feet; the least noise is unbearable; her voice is weak; she silences her husband and all his reproaches with a look. The doctor is called in; he advises exercise, and madam recovers. But she gets her way, good or bad, and beats all plots or plans by means of her migraine—the protector of illicit loves and the confounder of virtuous husbands.

For a thousand years in Greece not even the fathers of medicine noticed that the aches of the head were not unilateral. Alexander of Tralles made one distinction, namely, that the stomach was implicated in some headaches. Even this was forgotten, and for another thousand years there was no observation that resulted in distinctions. Then began a luxury of growth in nomenclature which has increased, until to-day all that one can say is that "there are as many kinds of migraine as there are heads that suffer." Even a few years ago Nietzsche had to protest to his scientific physicians that his disease was not migraine, because it was not on one side of his head. The spell or hypnotism of a badly-formed, meaningless word thus continues to-day to dominate observation and facts. And all this despite the truth that so many physicians (being students)—Lepois, Airy, Parry, Dubois Reymond, Travers, Fothergill, etc.—were sufferers from the disease.

Anthropologists have pretty nearly come to an agreement that prehistoric and savage trephining, so general in all races and times, was probably done for the purpose of relieving headache. The location of the hole made in the savage skull, in order to let out the evil spirit, does not warrant the conclusion that the headache was particularly on one side. It may have been so, but the arrow-makers, basket-weavers, etc., in whom it probably chiefly occurred, were not so discriminating as to point it out to the medicine men. Both probably thought of the living cranium as a more or less hollow organ, such as they found it in their ancient dead. The Greeks, and after them the Romans, and then the medieval nations, thought of the headache as a hemicranous ache, although many patients, and most of them in the crisis of the attack, found the ache as much on one side as the other.

*Classification and Etiology.*—Sauvages gives ten forms: ocular, dental, sinus, coryzal, hemorrhoidal, hysteric, purulent, insectal, nephralgic and lunatic. The great French Dictionary of Medicine finds it best to limit the varieties to two chief classes, the simple and the constitutional. Many authors recognize, 1, the idiopathic; 2, the sympathetic (disease of the viscera); 3, the symptomatic, i. e., from lesions of the encephalon or its envelopes. In Parr's Dictionary (1809), cephalalgia is divided into:

1. The mild, i. e., cephalalgia.
2. The inveterate, or cephalæa.
3. The one-sided—hemicrania, migraine, etc.
4. In one temple, crotaphos.
5. In the crown, i. e., clavus hystericus.

But he says it may be symptomatic and idiopathic, adding that it is often impossible to ascertain the disease of which it is a symptom, and that in some it is unconnected with any other complaint.

The cause of migraine, if known, would dictate the classification. The fruitlessness and self-contradictions reached by all the classifications that have been devised shows only what is frankly confessed, that none has had the hint of a suspicion of the true etiology. The primitive trephiners of prehistoric and present-day savage times were as sure of their pathology as of their therapeutics. Aretæus described migraine under the name of "heterocrania," and with considerable accuracy—better, in fact, than Galen. Aurelianus finds that women are more subject to it than men. Serapion thought the disease sprang from the digestive organs.

Alexander Trallianus continued the great blunder that has reigned supreme almost to our own day, and still rules many minds, that in the symptom complex we now call sickheadache the stomach is primarily at fault.

Charles Lepois, 1618, taught that migraine was caused by fermentation of the biliary matter which distended the membranes of the brain. Thus began the fashion of using those sacred mumbo-jumbo words, "bile," "biliousness," "bilious headache," "liver," etc., which have been of such potent-impotent service in the literary and social history of the last 200 years.

Wepfer ascribed the disease to stagnation of the exudated blood serum in one half of the head. Theories as metaphysical ruled the minds of Hoffman, Willis, Fordyce and others, who credited the disease to animal spirits. Tissot, in 1813, returned to the gastric theory. De villiers and Deschamps attribute it to disease of the frontal sinus. No one could for long get far away from the ocular idea or location. Schönlein called the disease cephalic hysteria; its seat in the nerves of the forehead and temple. Romberg called it cerebral neuralgia. Chaussier and Pinel charged the disease to neuritis of the seventh and especially the fifth nerve. Professor Brouillard thought the third nerve was the sinner. Auzias-Turenne thought compression of the trigeminus in the cavernous sinus was the cause. Calmeil said that sickheadache was a double lesion; the flow of blood to the central and to the peripheral system. Piorry held it to be due to an ascending neuralgia, starting from the nerves of the iris and pathologically reflected from the sensitive centers to other organs. Charcot insists on an intimate relation with rheumatism, gout, hemorrhoids and gravel. Of 30 women with nodular joint affections, 12 had previously had intense migraine.

The number of primary or secondary causes of the disease that have been noted by physicians' reports is astonishing. In Dubois Reymond's own case the attacks usually followed fasting or lack of food, and many have alluded to this. On the other hand, scarcely less frequently it is caused by the presence of food. Fothergill, with a hundred others, is sure that diet, "the kind or quantity, or both," is at the root of the mischief. He says that butter is the greatest cause, as "nothing more speedily and effectually gives the sickheadache, and sometimes within a few hours." The next most important articles are "melted butter, fat meats, spices, meat pies, hot buttered toast and malt liquors." English authors generally incline to the "bilious," gastric or intestinal cause of the disease. Fothergill's philosophy of the disease was that an acid or bitter bile in the empty stomach or duodenum, favored by certain foods, was the cause.

If fasting will not produce the disease, overeating will do it. Hunger and satiety are equally effective. Dubois Reymond, again, says his attacks were generally preceded by constipation. Wine, even sacramental wine, the least fragment of burnt pastry, are the great causes testified to by a physician as producing the attacks in himself for thirty years. The rôle of "biliousness," the "bile," "liver," "stomach," "dyspepsia," "disorder of the bowels," etc., is a big one in the great tragicomedy during the last several hundred years. Dr. Parry's own attacks were caused by the state of the stomach, "although they occurred without any feeling of indisposition at the time, either there or elsewhere. They generally *went off* with a movement in the stomach producing eructation." "Anything disagreeing with the stomach"—a hearty meal, meats, lack of meats, and every possible article of diet or lack of it—these *ad infinitum* have filled the accounts of patients and physicians. All of which is, of course, *post hoc* logic.

Perhaps next in emphasis and number of mentions after the digestional cause is the sexual. One physician has devoted a whole treatise to "catamenial megrim." Liveing at once stumbles on the fact that men have monthly attacks as well as women, but that does not deter him nor others from the hypnotism of coincidental and succedant disease viewed as cause. Puberty is a great disposer, but why it is so none can say, and the exceptions to the rule are far more numerous than the hits. The greatest reliance is placed on the supposed fact that the menopause brings cessation of migraine. Here, again, the inaccurate observation and domination of theory is noticed, because in the majority of cases the attacks increase in severity for ten or more years after the menopause, and in men the menopausal factor is hardly present and they also suffer up to about 60.

*Cephalalgia Spasmodica,* the Sick Headache, Parr describes in a separate paragraph, but his first sentence is, that he considers it separately only out of respect to Fothergill, for "this afflictive malady scarcely differs from the symptomatic head-ach, arising from the stomach."

Loud noises, foul air, smoke, drums, military music, review-days, etc., also, it seems determine attacks. But especially smelling, strong odors, particularly of drugs (turpentine, musk, valerian), even roses and flowers, are also effective. The smell of a postmortem room, of a hospital ward, always caused migraine in a great hospital physician, "one of the most brilliant writers," etc. He missed it but once, and that was when the wards had been watered with chlorinated water!

Meteorology is the great comfort of certain physicians in explaining migraine. In 1903 a great one has sought refuge in it when frightened by the ocular theory. Dr. LePois was attacked "on every change of the weather." Tissot and Labarraque are sure about atmospheric states, changes of season, or of weather. A large number of Symonds' patients blamed their attacks to weather, or no weather, to thunderstorms, etc. Dr. Airy's attacks were favored by windy weather—several of his family synchronously, and unknown to each other. Direction of the wind is another cause, frequent in Libert's cases. The southwesterly wind is effective at Zurich. Wagner, Nietzsche and others note the power of Föhn to cause the disease.

Mental excitement, emotion, vexation, distress, fright, passion, sexual emotion, etc., have been noted by Tissot, Symonds and many others as influential causes. "Nursing the mother through a long illness," "prolonged lactation," "poverty," "marriage ten years previously," frequent child-bearing, etc., are mentioned. On the other hand, freedom from the habitual attacks is noted during pregnancy.

Violent exertion, gymnastics, and just as frequently, fatigue, are charged with producing the disease. Lifting heavy weights, sudden effort, straining, running, a hard day's washing, skating, traveling, riding, are among other causes of the disease.

"Prolonged discharges," "prolonged indigestion," "disordered bowels," "impaired general health," "debility," "leucorrhea," are recorded observations. The cart is before the horse often, and often there is no horse or no cart.

"The state of sleep, or rather, perhaps, of waking," also causes the attacks, according to Liveing. One wonders if the neither-waking-or-sleeping state would not also do the same. To wake up from sleep seems to have been a frequent cause, and to be awakened before time. Prolonged watching, resistance to sleep, etc., are also listed.

The thousand causes that have been given remind one of the symptoms of the homeopathists in the "proving" of their drugs. However foolish scientifically they are also pathetic and confessions of impotence in the face of a great mystery.

In Symonds' 90 cases the causes are thus classified:

| | |
|---|---|
| Emotional disturbance.. | 53 |
| Indiscretions of diet... | 19 |
| Denial of diet as cause | 62 |
| Action of the bowels.. | 12 |
| Denial of this cause.. | 54 |
| Fatigue | 32 |
| Catamenia (out of 76) | 35 |
| Atmospheric states | 48 |
| Thunder | 25 |

Analysis of these figures is both edifying and mystifying and amusing.

Dubois Reymond held to the theory of a tetanization of the cervical sympathetic, and the great modern French *Dictionnaire des Sciences Médicales* agrees that this is the best theory.

The bibliography of the subject would occupy a volume. The Index Catalogue and the Monographs of Liveing, Spitzer, Cornu and Mobius may be consulted for references. All text-books on general medicine and nervous diseases, of course, add to the literature, without adding any clarification of the subject.

Hooper's Medical Dictionary says migraine "arises from a state of the stomach," and Parr's Dictionary traces causes to bony fragments, exostoses, tumors, worms in the brain, etc. Parr finally breaks down, however, and in despair says: "Authors have endeavored to distinguish by the particular kinds of pain, which of these causes may have produced it, but language fails in describing the different feelings and their variety." One of the reasons for the despair of Parr and of all others is that the whole life of the patient was not observed. The clinic was of the day, not biographic. This disease is one of the whole life.

Airy and Förster think cerebral anemia is the cause. Sarda says: "How many dyspeptics have hemicrania! How many migrainics have no dyspepsia?" Liveing's view is that the disease is of the nature of a nerve storm from the sensory centers, and is related to epilepsy.

As for definitions, one modern one may serve for many: "A complex neuralgia of the nervous centers, of the nerves of sensation and of vasomotor nerves, characterized by direct or reflex modifications of the intellect, of sensibility, and of local circulation, also of general circulation and of great functions." Almost all authors emphasize the rôle of "heredity"—"the unknown god ignorantly worshipped." Osler's summary is, "the nature of the disease is unknown."

In a general way all theories may be grouped into four large classes:

1. The cause is central. The authors upholding this view are Liveing, Romberg, Anstie, Leubuscher, Jackson, Gowers, Möbius and others.
2. The vasomotor system is at fault. The advocating authors, according to Spitzer, are Dubois Reymond, Möllendorf, Eulenberg, Mauthner, Siegrist, Oppenheim, Whytt, Latham, Lauder-Brunton, Hammond, Wilks, Pemberton, Peake, Handford, Charcot, Galezowski, Féré, Thomayer, Lyon, Antonelli, d'Astros, etc.
3. Toxins are the etiologic factors—held by Galen, Serapion, Brunton, Hecker, Haig, Navarre, Wallace, Claus, Rachford, Steckel, Strümpell, etc.
4. Reflexes are the causes, supported by Tissot, Hack, Schäffer, Schech, Sommerbrodt, Zien, Dobisch, Martin, Seguin, Greenwood, Terrien, etc.

Each one of these may be and are combined with either one, two or three of the others, until only the most patient of experts can distinguish the divisional distinctions. To all others confusion soon becomes ever worse confounded with each hour's study. When one has become migrainous with attempts even to understand the theories he will agree with Osler and others that the nature of the disease is unknown. *"Autant de tetes, autant de migraines!"*

*Prodromal Symptoms.*—The typical attack is said to be usually ushered in by pain over, in, behind or above one eye, or in one temple, or by vague symptoms of gastric malaise, anorexia, lassitude, sleeplessness, or, conversely, on reading or writing, with sleepiness. The prodromes that have been noted are many. With or without the pain in the forehead, eyes or temple (or in all three), scotoma scintillans may precede the attack, and a number of authors and many practitioners still think this is a necessary part or prodrome of "true migraine." (This symptom has itself been called "ophthalmic migraine.") But if this is so, we can then have migraine without unilateralism, without pain and without implication of the digestive organs, for I am sure that close observation of many clinical cases will demstrate that the majority of attacks of sickheadache are not preceded by scotoma scintillans; and that in fully a half of cases of scotoma this symptom is followed by no headache or other symptom whatever.

I have scrutinized the facts in not less than a thousand private cases of typical sickheadache, and myself and assistant are sure that at least half do not have the prodrome. On the other hand, questioning all patients who have had this symptom, shows that the same proportion do not have any headache following. Until I secured a perfect correction of my own ametropia I had frequent attacks of scotoma scintillans—numbering several hundred in twenty-five years—and I never had a headache in my life. Hippus and hemianopsia are also other ocular prodromes.

*"The Typical Attack."*—The most common, and especially the initial symptom, is that supposed to be expressed by the name—a pain in one side of the head. This pain is almost always described as over one eye, in it, or behind it, or in one temple. One after another there are or may be additional symptoms until the whole encephalon becomes unendurably painful and sensitive, and nausea and indescribable wretchedness follows, violent emesis then ensues, lasting for a few minutes, or for days; there is then a sudden clearing, and, in otherwise healthy and strong natures, a quick return to health. The recovery may be slower in the weak or otherwise unhealthy. Despite the fact that the digestive disorder is a late or last and infrequent symptom of the disease the gastric origin is still the favorite theory today. But it must not be forgotten that the testimony of all writers agrees with that of personal clinical experience: the number of atypical cases is a hundred times greater than that of the so-called typical. The so-called typical disease is the severe one, that in which there will be at least the two chief symptoms of headache and nausea. Hence the applicability of the term sickheadache to this condition. But, again, the vast majority of cases of what is evidently the same disease, do not reach the extreme of nausea or even of vomiting.

One may with truth say that there is no typical disease. The vast majority of cases have no aura. This pathologic house has no portico or front door. Almost as many cases have the aura only, without other symptoms. The house, then, consists solely of front door. Parkman and Spencer and others avoided what the writers would call migraine, by most careful and deft avoidance of the causes of it, and yet their disease was essentially the same as that of George Eliot and Nietzsche. Hemicrania is often not hemicrania, i. e., it is bilateral instead of unilateral. All pain in the head may be absent and the disease have the same cause as in headache cases. The digestional reflexes are in the great majority of cases entirely absent, or they may be of a hundred types. What shall, therefore, be said of a disease that has no true typical symptoms, which hardly ever has all of those called so, which usually has only one, which may consist solely of a prodrome, or without one of the usually recognized symptoms? *It is time that it were reborn, renamed, rechristened and reëducated.*

The recognition of the essential morbid condition is further rendered more difficult by the intermixture of an infinite variety of symptoms that often mask or complicate the clinical course, complaints and diagnosis beyond recognition. Thus has been completed the utter chaos which to-day characterizes the whole subject. There is no agreement among a multitude of theorists; there is the most ridiculous weedy growth of contradictions and inconsequence concerning etiology; and, of course, there is no therapeutics whatever. Migraine is the puzzle and the opprobrium of medicine. The conclusion of the article in the greatest medical encyclopedia is: *Autaut de tetes autaut de migraines,* which, translated into scientific language means that the almost unique cause of migraine, astigmatism, etc., differs in each case; the exciting cause, occupation and use at near-range of the eyes, differs no less; the soil, i. e., the nervous and digestive systems, into which this infinitely varying seed falls, are also never alike in two cases. How certain, therefore, must it be that the morbid results are so lawless and seemingly illogical.

The terminal stages of the attacks also illustrate the death-and-life struggle of the organism with the excruciating disease. The one, two, or three-day vomiting and retching described in the cases of Mrs. Carlyle, Nietzsche, etc., is suggestive. There is sometimes a flow of tears, sometimes abundant secretion of urine, a mucous flux from the nose, lavish sweating of the feet, hands, or half of the face; there may be nose-bleeding or even arterial hemorrhage.

A large clinical experience with migrainous patients shows that their headaches are of an apparently amazing variety of kinds, and seemingly, of causes. An examination of the literature also illustrates the same fact, each of these kinds by one or by others being called or described as migrainous. *The mere index or enumeration* of these kinds of headache would fill many pages. In the first place there is a long list of headaches plainly due to organic and systemic diseases, such as tumor and traumatism of the brain, meningitis, fevers, infectious diseases, etc. These are, of course, excluded. They are few in number compared to the nonsymptomatic and functional cases, but in many treatises they fill most if not all of the field of vision. Of the functional kinds one may likewise construct a huge list: the nervous sick, periodic, hereditary, constitutional, dietary, hemicranic, menstrual, ocular, nasal, dental, constipational, bilious, indigestional; those from intellectual overwork, physical exhaustion, worry, lack of food, from study, bad light, bad ventilation; from coryza, influenza, rheumatism, uterine disease, pregnancy, hysteria, anemia, diseases of the spinal cord, of syphilis, and so on, and so on. And, finally, then, is a very large class that can not be ascribed even to the vaguest and most far-off cause. Any one, two or dozen of the kinds may be mixed in all proportions in any one case, and only omniscience—not possessed at least by young practitioners—could discern the explanation and dissolve the mystery.

Lastly, the location, character and degree of the ache in, about, on and below the head, in spots, in halves, or of the whole, make confusion worse confounded.

(*To be continued.*)

## Clinical Report.

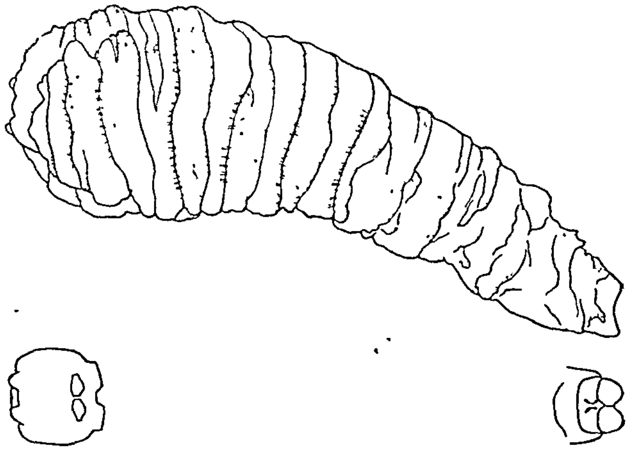
### A PARASITIC MAGGOT,

### GASTROPHILUS EPILEPSALIS (?), IN THE SKIN OF *AN INFANT.*

F. L. WASHBURN, A.M.
MINNESOTA STATE ENTOMOLOGIST.
ST. ANTHONY PARK, MINN.

In September last Dr. Burnside Foster, St. Paul, Minn., sent me for identification some maggots in alcohol which had been taken from a patient, August 15, at Superior, Wis. He stated that the patient was a female infant three weeks of age, born prematurely at the seventh month and bottle fed from birth. One of these maggots came from a pustule on the back of the neck, one from the palm of the hand, one from beneath the jaw and one from between the great and second toes of the right foot. He further stated that the infant had slept in its carriage out of doors for many hours nearly every day since its birth.

I at first thought that these dipterous maggots belonged to the old genus *Lucilia,* but having no specimens in alcohol with which to compare them, I sent them to a specialist on diptera at Washington, D. C., without data. This specialist declared the specimens to be *Gastrophilus epilepsalis* (French), French names, and describes this species in the *Canadian Entomologist*, vol. 32. It was named from a larva, great quantities of which were found in the evacuations of a child subject to periodic epileptic spasms. As these attacks ceased for a time after the use of purging medicines by means of which large numbers of the maggots were voided, Professor French in his article appears to have assumed curiously enough that the spasms were caused by the "reproduction of the larvæ in the intestines." This statement is absurd, because with a few rare and well-identified exceptions reproduction in insects is confined to the adult or perfect form. He called these parasites *G. epilepsalis* because the patient had all the symptoms of epilepsy, the patient having globus hystericus with the spasms and the other usual symptoms, including mental aberration, accompanying the attacks. This intestinal parasite evidently has no connection whatever with epilepsy, and is wrongly named. The curious part of the affair, as far as the writer is concerned, is the fact that the Washington specialist declared that Dr. Foster's maggots, which were cutaneous, were identical with Professor French's type, an intestinal parasite. Two prominent entomologists take exception to his identification.



Maggot obtained from infant by Dr. Burnside Foster, enlarged 17 times.

It is a pity no imagoes were reared from these Wisconsin larvæ, for that would have settled the identification. Certainly much remains to be found out about this variety.

In this connection Prof. John B. Smith, state entomologist of New Jersey, cites a curious case of a *Cuterebra* larva, belonging to the *Oestridæ*, being taken from the neck of a woman, the supposition being at first entertained by her physician as well as by herself that she was suffering from a boil, and not until the treatment was changed and the "boil" opened was it discovered that the trouble was caused by a dipterous parasite. *Cuterebra* is a bot fly, affecting normally rabbits and squirrels. The genus *Gastrophilus* belongs to the family of flies known as *Oestridæ*, types of which are found in the bot fly of the horse and in the so-called ox warble which renders the backs of cattle sore and seriously impairs the value of the hides. Both of these flies lay their eggs on the hairs, which eggs are later licked off. thus finding their way into the alimentary canal.

---

## New Instrument.

### A SERVICEABLE FORM OF CAPILLARY ELECTROMETER.

C. C. GUTHRIE, S.B., M.D.

(From the Hull Physiological Laboratory, University of Chicago.) CHICAGO.

I have been using the capillary electrometer, figured below, for some time, and it has proved so satisfactory that I consider it worthy of a brief description. I ordinarily work with the capillary tube horizontal and the description will be of it in that position.

Figure 1 shows the appearance of the capillary and cup when viewed from above. A is a glass tube drawn into a capillary and fused into the acid cup B at X. The superior and inferior surfaces of the cup B are flat and parallel. Each surface is dilated into a small reservoir C and E (see Fig. 2). C has a hole in the top which is sealed with acid-proof wax after the cup is filled with acid, care being taken that a large air-bubble remains in the reservoir. E serves as a reservoir for the overflow mercury from the capillary tube and has a platinum wire, G, fused into the bottom. The capillary is in contact with the internal surface, and in the median line of the top wall of the acid cup. F is a platinum wire fused into the tube, A. The tube and cup are mounted on a fiber base, as shown in Figures 3 and 4, the platinum wires, F and G, being connected with wires running to the short-circuiting key, O, and binding posts, P. and P′. Tube A (Fig. 3) is connected by means of a piece of antimony rubber tubing with the glass pressure reservoir, K, which is provided with a mercury trap and is fastened to the post, J, by means of an adjustable clip, L. The post is made with a hinge joint which permits the use of the instrument with the capillary in either a horizontal or perpendicular position. The post is graduated in mm. to show the mercury pressure. In Figure 4 a modification of the pressure arrangement is shown, with a longer tube, A, bent at a right angle so that the end, which is provided with a mercury trap, is brought into contact with the air-pressure reservoir, Q, to which it is firmly cemented. The pressure in this form is regulated by the screw, N. The hole, I, is closed by cementing a sheet of glass across the bottom flush with the inferior surface of the base (the object of this being to protect the microscope in case the acid cup should be accidentally broken). The instrument is fastened to the stage of an ordinary microscope by clips.

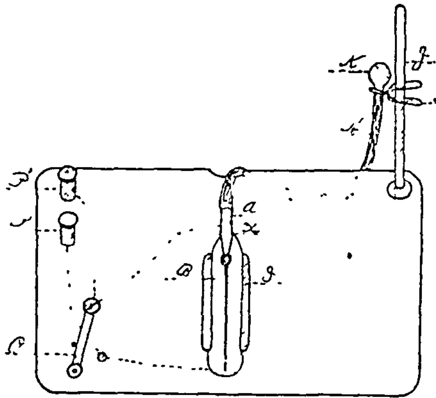


Fig 3

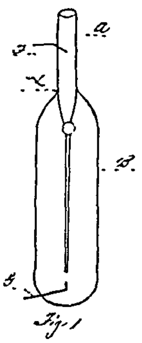

Fig 1

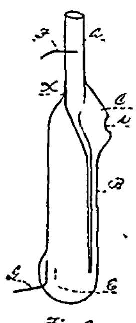

Fig 2

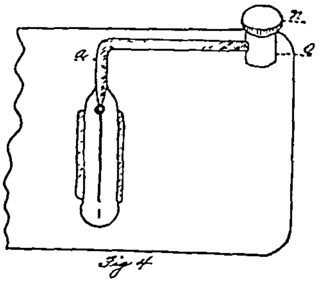

Fig 4

This form is as sensitive as the ordinary types. It is always ready for use; it may be turned in any position without spilling acid or mercury; and it is not easily broken or got out of order.

My thanks are due Dr. E. P. Lyon for valuable suggestions; and Mr. F. H. Rieske for his assistance in working out the mechanical details of the base, and assembling the parts.

## A CRYSTALLINE PRODUCT OF VENOM.

In a former issue[1] we noted editorially certain recent advances in the study of venoms, and emphasized the importance of the new facts in relation to the general subject of immunity. The two most important points mentioned were that venom alone is not poisonous but becomes so in the body in the presence of serum complement (Flexner and Noguchi); and that, moreover, a known chemical substance, lecithin, is capable of assuming the complementing or activating rôle for the venom.

Kyes[2] has followed up the latter discovery with another which may be of far-reaching importance in studies of toxins and other substances concerned in immunity. Having a known chemical substance in the form of lecithin which may act as complement, its relation to the active substance in the venom became an important object of investigation. It may first be recalled that Kyes discovered the existence of an endocomplement in the red blood cells, which was able to unite with the venom to cause the solution of the erythrocytes. This endocomplement turned out to be without doubt the lecithin which is normally bound to the stroma of the corpuscles. Inasmuch as the blood of all animals was not hemolyzed by venom when the former was freed from serum it seemed probable that the lecithin in such cases was more firmly bound to the corpuscles than in the bloods which were easily hemolyzed under these conditions. If lecithin, in complementing, acts as serum complement usually does it would combine with the venom intermediary body only after the latter had united with the corpuscles. However, under certain conditions even serum complement may unite with the intermediary bodies without the medium of a cell. This phenomenon has been termed deviation (Ablenkung) of the complement—the phenomenon of Neisser and Wechsberg. The most important feature of Kyes' latest work is that he has been able to bring about just such a union of the activating lecithin and the venom amboceptor (as the active substance would be called according to Ehrlich's nomenclature) and to obtain this new body in the form of a pulverulent precipitate. A 20 per cent. solution of lecithin in chloroform is made, and over this is placed 40 c.c. of a 1 per cent. solution of dried venom in 0.85 per cent. sodium chlorid solution. This is put into a shaking apparatus for two hours and then centrifugalized. The shaking produces intimate contact of the chloroform soluble lecithin with the water soluble venom and during the process the union of lecithin and venom has occurred, the new product remaining in solution in the chloroform. From the chloroform it is precipitated by the addition of five volumes of pure ether. The precipitate is washed repeatedly in ether and finally separated by centrifugation and dried, or it may be kept indefinitely under ether. The product was found to contain quantitatively the toxic principle of the original venom. It had, moreover, a wider range of activity than the venom, inasmuch as the washed blood of certain animals which was resistant to crude venom was now dissolved with the same readiness as the more susceptible bloods by the precipitated product—cobra-lecithid. The explanation lies in this, that the precipitate carries with it its own complementing substance, i. e., the lecithin portion of the compound. Interest also attaches to another point. If the cobra-lecithid is dissolved in water, there separates in a short time a new precipitate having a crystalline form—a "secondary lecithid" possessing the same hemolytic power as the "primary lecithid."

It will be remembered that in addition to the hemolyzing substance venom also contains a neurotoxic element. Myers, in 1900, demonstrated the difference in cellular affinities of the two active principles. Kyes accomplished the separation of the two, incidental to the precipitation of the primary lecithid. The neurotoxin remained in the salt solution while the hemolytic amboceptors were taken up in the chloroform-lecithin solution. Of the various results obtained with this substance, the one of most importance is that immunization with the crystalline product yields a specific antibody for the hemolytic agent of the venom as well as for the cobra-lecithid.

It is difficult to appreciate the full significance of having this, first, pure, crystalline compound of a toxin. Other toxins have been brought down mechanically with the albuminous bodies of a medium by the use of ammonium sulphate and other precipitating agents, but this is the nearest approach so far to the chemical isolation of one of those substances so important to life and general economy. Scientists have had to content themselves with observing the remarkable effects of toxins and immune serums, and with theorizing as to their probable albuminoid nature and their mode of action. They have never been able to see and analyze chemically the pure substance. It is reasonable to suppose that the work of Kyes may prove a point of departure for investigations of the greatest importance. The possibility of being able to obtain certain bodies in pure concentrated form may mean more than we can at present appreciate. With such substances it may be possible to obtain a heretofore unheard-of degree of immunity, and yield us more powerful antiserums. Perhaps various other toxins depend for their activity on substances contained in the cells themselves. It does not follow that it would be lecithin in all cases, so all toxins may never be reduced to lecithids. There is, of course, abundant room for theorizing and an unlimited field for investigations of a like nature.

## THE RESULTS AND PROSPECTS OF TENEMENT-HOUSE REFORM ABROAD.

The most striking victories of sanitary reform have been those won in and over the slums of the great English and Continental cities, and the call to arms has usually come through the medical profession, for although these reeking nests of unwashed humanity have shocked the moral sense of the public as nurseries of crime and physical degeneracy, yet their most powerful appeal for vigorous action has ever been through becoming the starting point of some deadly epidemic. Disease is the revenge which the submerged tenth takes on the careless selfishness of the upper social strata. As long ago as 1838 a serious outbreak of disease in London, beginning in the east end, inspired an extensive investigation into the conditions of life in certain districts, the report of which came like a revelation to the rest of the city. Nearly 1,500 families were found living in 2,200 rooms and with only 2,500 beds among them, 923 of them having only one room and 625 only one bed. What this means as to the possibilities for health and decency needs no explanation.

For many years a vigorous campaign has been waged against the London slum. Some of the worst, like the notorious Seven Dials, have been practically wiped out of existence by driving broad streets and avenues through them, and thus letting air, sunlight and a better class of buildings penetrate the whole neighborhood. In others, like the Boundary Street area in Bethnal Green, the old buildings were torn down block by block and new model tenements erected in their place. The last of these buildings were dedicated by the Prince of Wales in 1900, and the whole series form a unique tenement village, covering thirteen acres, and with accommodations for 6,000 people, ingeniously grouped around parks, playgrounds and public baths. The death rate of the old district was 26 per 1,000; that of the new village does not exceed 16.

The problem is, however, in some ways simpler in London than in New York, since the slum buildings are mostly old tumble-down two-story or three-story or even cottage-built hovels, whose condemnation and destruction cost little in addition to the ground values, and as there has long been a provision in the building laws restricting the height of any building to two-thirds of the width of the street on which it faces, and strict regulations as to the cubic space per inhabitant, air and light are now enforced, and the evil is not perpetuating itself as in Manhattan Island. It is merely a question of destroying that which is already beginning to decay.

Certain it is that the London slum is rapidly becoming a *rara avis*, which must be sought for diligently if one would find it, and experienced workers go so far as to declare that even at its worst it is a "Garden of Eden" compared to the New York variety. The two forces which have mainly contributed to this desirable condition of affairs have been intelligent legislation as to light, air-space, plumbing, etc., and the discovery, through the erection of model buildings, as a work of philanthropy, especially the famous Peabody Fund, that this class of tenements could actually be made a paying investment. The original gift of this great philanthropist was $2,500,000, with which eighteen separate blocks of buildings were erected in various parts of the city, and such rents fixed as would secure a return of 3 per cent. on the investment. This is returned to the fund, so that it is continuously renewing itself and new buildings are steadily being constructed. As an endless chain of beneficence, this donation is certainly unsurpassed in the annals of charity.

Other examples might be cited to show that the medical profession, as sanitary reformers, is entrenched in a perfectly impregnable position as to its right to say to a prospective builder, "You must conform to such and such requirements for health and safety," inasmuch as it has been abundantly shown that this can be done without depriving him of a legitimate profit on his investment. This is the line which has been followed by the Tenement House Commission in New York appointed by President Roosevelt when he was governor. From this point of view, all that is needed in the future is a firm stand, rigorous and intelligent, holding tenement-house builders and investors to a certain standard of lighting, space and ventilation.

Of course, there will be a furious outcry from the unscrupulous class of builders and investors—and they are exceedingly numerous, if not a majority—who are determined to get every inch of space and every dollar of rent that their building can be made to yield; but when the public opinion once knows that the insistence by the city on these sanitary requirements is merely a question of cutting down profits of 15, 20 and even 30 per cent. per annum to the more reasonable 6, 7 or 10 per cent., it will stand no trifling with such serious conditions and will crystallize into a sentiment which even city councils must respect.

The other factor which is operating so powerfully in the solution of this problem, is that of rapid and cheap transportation. Steam made an enormous improvement and electricity has increased it 100 per cent., and is apparently not much more than at the threshold of its achievements in this regard.

We as reformers may, we believe, look forward confidently to a time when no more than a certain degree of density per acre of population will be tolerated in any of our large cities. While the skyscraper continues to flourish apace, the central parts of our cities will become more and more exclusively devoted to business purposes and their only inhabitants after business hours will be the few janitors, caretakers and watchmen, with their families, required to protect from fire and loss. Indeed, the London County Council has already begun to recognize this principle, and to discourage the building of even model tenements for laboring men within the more congested districts. In their place it is now carrying out a broad and far-seeing scheme of suburban colonization, building instead of model tenement blocks with their hundred rooms to the acre, acres of model cottages out in selected suburbs, making at the same time special arrangements with the railway and electric companies for reduced rates of transportation for their tenants. We may, perhaps, even look forward to a Utopia in which the awful effects of overcrowding in city life will be confined entirely to men of adult age and during business hours only, and when women and children will escape them entirely—living out in beautiful model suburb homes. The gain in health, in happiness, in home life and in facilities for healthful and natural education for the children will be something enormous.

The same principle may of course be carried out in our American cities. Indeed, they are already being applied in a large majority of them, without any official interference on the part of the municipal authorities. In our American cities the classic jibe of Thackeray at Washington, "a city of magnificent distances," is one of their proudest boasts. In one of them, however, and that the largest—New York—the problem presents itself in an even more acute and difficult form than in London. Not only has it, as has already been mentioned, worse slums than any to be found in the world's metropolis, but from the peculiar geographic formation of Manhattan Island, the solution of the problem, by means of rapid, cheap and safe transportation into the surrounding suburbs, is peculiarly difficult. Now, however, that the proposal for the great Pennsylvania tunnel has been accepted, giving it direct communication with the mainland on one side and Long Island on the other, we may hope for the beginning of better days.

## THE SIGNIFICANCE OF ALBUMIN AND CASTS IN SURGICAL PATIENTS.

There has been a belief among surgeons for many years that ether is so irritating to the kidneys that it should not be used with patients suffering from nephritis. Some advocates of chloroform consider the irritating effects of ether great enough even to cause nephritis in patients with kidneys normal before operation. As with many other beliefs we doubt if most of those who have held them could give their reasons for doing so. Probably a statement which has been made in standard text-books on therapeutics in several successive editions is partly responsible for this somewhat widespread opinion. These books state that chloroform is more irritating to the kidneys than ether, but the large quantity of the latter necessary for anesthesia makes it less safe. No facts are given on which to base this statement.

In a paper read recently by Dr. John C. Munro,[1] is contributed some valuable information on this subject based on the records of 4,185 cases treated in the surgical wards of the Boston City Hospital. Albumin and casts were found in the urine of 500 cases admitted within three years. From this number are excluded patients obviously suffering from renal degeneration. Practically every form of injury and disease are included in the series, the majority being of a serious nature. At least 60 per cent. underwent operation; about 12 per cent. suffered from fracture, and in many cases the etherization was of long duration. The cause of the frequent occurrence of albumin and casts, affecting approximately 35 per cent. of all surgical cases, is difficult to determine. The use of alcohol, insufficient or improper food and hard work are mentioned as possible causes. Unhygienic surroundings and improper clothing are probable factors in children. In a number of septic cases the renal disturbance subsided as soon as drainage was established by operation. The recoveries were quite satisfactory in 437 of these patients, there being no complications for which there was not adequate explanation on grounds independent of any kidney lesion. Among 63 cases that died, with 2 exceptions, the conditions found at postmortem examination did not give any weight to the urinary conditions as a cause of the fatal result. Munro concludes that we should expect evidence of renal irritation in over one-third of the surgical patients in a municipal hospital. A trace of albumin with or without hyaline and granular casts, unattended by any other evidence of renal damage, should not influence the prognosis in surgical disease or operation. The proportion of patients thus affected in young and otherwise healthy children is probably as great as in adults. The presence of albumin and casts should lead us to watch for other signs of organic degeneration which might unfavorably influence operation or recovery. Albumin and casts alone he does not consider a contraindication to the administration of ether.

This subject seems to us of great practical importance for everyone called on to administer an anesthetic, no matter how infrequently. The greater relative safety of ether as a general anesthetic at the time of operation is becoming more and more generally acknowledged. Prejudice has much to do with our beliefs in such matters, and until some of the older generation of surgeons die there will be a considerable number who will adhere to chloroform as the best general anesthetic. This is particularly true of the surgeons of Great Britain and Germany. Many of these mention the dangerous after-effects on the kidneys and lungs as the factors which keep them from using ether, though they admit it is safer at the time of operation. What we want is definite information as to whether these dangerous after-effects really do or do not occur, and by the careful study of so large a number of cases Munro has done much to settle the question so far as the kidneys are concerned. In this, as in many other matters in surgery, there has been too great a tendency to depend on general impressions rather than to seek for definite information by careful study of clinical material.

### DEPRESSANT DRUGS AND SUDDEN DEATHS.

It is very interesting to examine the statistics of sudden death from heart disease in New York City during the last three years. In 1900 there were registered 4,069 deaths from heart disease in the greater city of New York in a population of approximately 3,445,000, while in 1901 there were 4,626 such deaths, the population having presumably increased about 100,000. Thus there was an increased ratio of sudden deaths to population. In 1902 the number of sudden deaths reported from heart disease had increased still further to 5,461. Calculating the percentages of sudden deaths from heart disease to population, allowing for the before-mentioned increase of population, the deaths of this kind to each thousand were, in 1900, 1.18; in 1901, 1.31; in 1902, 1.34.

For the year 1903 there was a decrease in the number of deaths from this cause, so that the ratio was only 1.28 per thousand. There has been some discussion among sanitarians and public-health officials as to the reason for this decrease. A portion of the decrease has been ascribed definitely—and with considerable plausibility—to a certain cause. At the beginning of last year the board of health, suspecting that many prescriptions for phenacetin were being filled by druggists with acetanilid, or with a mixture of phenacetin and acetanilid, sent inspectors to obtain definite information on this matter. Altogether 373 samples of phenacetin were bought from the same number of drug stores in various parts of the city, phenacetin being specially asked for and in some instances even obtained, on a physician's prescription. Of the 373 samples, 58 were pure phenacetin; 315 were adulterated with cheaper drugs, mainly acetanilid, and in 267 cases containing more acetanilid than phenacetin; 32 samples were pure acetanilid. The commissioner made these facts public, and threatened to expose and prosecute all druggists who would hereafter be found committing this misdemeanor.

It is very interesting at least to find that a single year after the investigation and supposed consequent reform on the part of the dispensing pharmacists, there should be a slight reduction in the actual sudden death rate from heart disease, and that at a time when for many years there has been a constant increase in the death rate from this cause. It is well known that acetanilid is a distinctly depressant drug for the heart. Professor Jacobi of New York always insists that it is an actual tissue poison, to be used only with great care, and many therapeutists teaching that it is the underlying cause for the increase in reported sudden deaths that has occurred in recent years.

This question of the evil of depressant drugs is all the more interesting because of the freedom with which so-called headache powders, mainly composed of acetanilid and other heart depressants, are now so commonly bought and sold. Many women, and even men, think nothing of stepping into a drug store and asking for something for a headache. The headache powders that are dispensed to them so freely always contain acetanilid, and great harm is being done in this way. It is probable that a similar investigation in other cities of the country might also furnish instructive facts. Certain it is that proper legal regulation of the sale of such depressant drugs, so that they could not be dispensed except under the direction of a competent physician, would in the long run have a beneficial effect on the sudden death rate from heart disease. This cause of sudden death is becoming more frequent in this country, and is a serious menace for those suffering from even slight forms of heart disease if they are so foolish as to take these remedies.

### ARTIFICIAL CAMPHOR.

Prior to 1828 chemists made a sharp distinction between organic and inorganic compounds, it being supposed that the latter are capable of preparation in the laboratory, while the former are formed only in the living organism, animal or vegetable, under the influence of a particular force—the life force. This view was rendered untenable by Wohler's discovery that urea, a typical secretion of the animal organism, can be prepared synthetically from cyanic acid and ammonia, two inorganic compounds. Many other "organic" compounds, such as acetic acid, lactic acid, glycerin and sugar have since been made synthetically, and as our knowledge of chemistry increased the old idea about a vital force has lost greatly in significance. We know now that the same chemical forces act both in the organic and inorganic worlds. It is well known that most of the vanilla extract now found on the market is not derived from the vanilla bean, but from coal tar. This coal tar furnishes a large number of other substances which are used in medicine and in the arts. Among these may be mentioned the various analgesics, anilin dyes and perfumes. Indigo and alcohol have also been made from their inorganic constituents, and recently chemists have discovered a method of making camphor synthetically, which makes the manufacture of this substance a profitable industry. Camphor has the formula $C_{16}H_{16}O$, and is an organic compound which was formerly derived only from the camphor-tree *Cinnamomum camphora*, by distilling the chips with water and purifying the product by sublimation. The camphor trees have, however, been growing scarce, and as a result the price of camphor has of late been very high. Japan has a monopoly on the natural product, but this monopoly has now been broken by the manufacture in this country of artificial camphor from turpentine. Turpentine has the formula of $C_{10}H_{16}$ and can be oxidized to $C_{10}H_{16}O$ by heating it with oxalic acid. A ton of turpentine is heated at one time with a quantity of oxalic acid, and out of this mixture is distilled the purest variety of camphor. It takes fifteen hours to complete a lot, and the yield of camphor is 25 to 30 per cent. of the weight of turpentine. Various other valuable oils are obtained at the same time as by-products.

### THE ETIOLOGY AND PATHOGENESIS OF AORTIC ANEURISM.

Once developed, there seems to be little hope for cure of aneurism of the aorta. Amelioration may be afforded, perhaps for a long period, by the introduction of gold wire and the passage of a galvanic current, and some good results have been reported from the use of gelatin subcutaneously. The prognosis is, however, never encouraging, and more is to be hoped for, in this instance, as in many others, from prophylactic measures rather than the treatment of the developed condition. Of the various causes that have been held responsible for aortic aneurism, by far the most important is syphilis, and the recognition of this fact means that the physician especially must do all in his power to prevent the spread of this disease, and to insist on its thorough and long-continued treatment when it occurs. Modern medicine is preventive medicine. Dr. Hans Arnsperger[1] has analyzed 37 cases of aneurism of the aorta—35 in men and 2 in women—observed at the Medical Clinic of the University of Heidelberg in the service of Professor Erb, not including 15 presenting merely dilatation of the aorta. Of the 35 cases in men, 15 were instances of diffuse and 20 of circumscribed aneurism, insofar as could be determined by physical examination without autopsy. Of this entire number a history of syphilis was obtained in 65.7 per cent. of the cases—in 48.6 per cent. with certainty and in 17.1 per cent. with probability; of the cases of diffuse aneurism a history of syphilis was obtained in 26.6 per cent.—in 20 per cent. with certainty and in 6.6 with probability; and of the cases of sacculated aneurism a history of syphilis was obtained in 95 per cent.—in 70 per cent. with certainty. As a result of these observations and of a study of the views of others on the same subject, it is pointed out that clinical-statistical investigation discloses with certainty that, in an exceedingly large proportion of cases of aortic aneurism, a history of syphilis can be obtained, while all other factors admitted to be of etiologic significance are demonstrable in only a small percentage. The conclusion seems, therefore, justified that syphilis is the most important factor in the etiology of aortic aneurism. Pathologic-anatomic investigation shows that the changes found in cases of aortic aneurism generally correspond to those observed in cases of syphilitic disease of the aorta. The alterations exhibit no certain, pathognomonic feature, but they conform with those recognized as certainly syphilitic. The findings suggestive of traumatism, such as primary rupture of the elastic coat, are in large part based on error. Experimental investigation teaches that inflammatory processes induced artificially may result in the development of aneurism, but these can not be caused by traumatic effects on the walls of the vessels, or only as a transient phenomenon. All of these considerations would seem to justify the conclusion that aortic aneurism is, in the overwhelming majority of cases, due to inflammatory processes in the wall of the aorta and that syphilitic disease of the vessel-wall plays a particularly important part in the etiology and pathogenesis of aortic aneurism.

### FERTILIZATION AND THE PRODUCTION OF SEX.

The production of sex was recently discussed editorially[1] and some recent studies of the subject noticed. Still another memoir bearing on the subject is that of Schuecking[2] which, however, covers a wider biologic range of study and includes a consideration of the essentials of fertilization as they occur both in the lower organisms and in the human species. A certain portion of Schuecking's experiments on the artificial fertilization of certain marine organisms was noticed in a former issue[3] of The Journal, but more recently he has published some interesting and perhaps important deductions. He finds that the taking up of water is a preliminary essential for both artificial fertilization and parthenogenesis and that fertilization is more certain the larger the number of spermatozoa. It is rather incomprehensible why so large a number should be required—some two or three hundred millions—when but a single one is sufficient for fertilization, and he thinks he finds an explanation in his observation. The excessive number appears to increase the protoplasmic excitation and water inbibition, thereby to overcome the acidity of the secretions of the parts which are increased (in the human species) from the close of one menstrual period to another, and it is only in this way that conception is able to take place. Assuming that the sex is established in the ovum before conception, which certain facts seem to indicate—such as the similarity of sex from single ovum twins—and which has been demonstrated in some of the lower animals, he holds that the female ovum requires a much larger quantity of water to start its development than does the male ovum and thus explains certain facts, such as the increase of male children after a war when oligospermia may be assumed to exist. The facts suggest that sterility might be combated by a preliminary injection of weak alkaline fluids together with massage of the pelvic organs after deposition of the semen. Schuecking's deductions are certainly suggestive as regards not only the mechanism of fertilization, but the question of the production of sex which is so much to the front of late years.

## Medical News.

### GEORGIA.

**Still More Smallpox.**—It is reported that there are at present from 15 to 20 cases of smallpox among negroes at Stillmore.

**Memorial to Dr. Gaston.**—The Atlanta Society of Medicine at its last meeting adopted resolutions in memory of the late Dr. J. McFadden Gaston.

**Cornerstone Laid.**—The cornerstone of the New Hospital for Incurables, Atlanta, was laid with appropriate ceremonies, January 3. The building is expected to cost about $12,000.

**Physician Shoots Physician.**—Dr. Otis B. Sally, Augusta, was shot and seriously wounded by Dr. J. E. Durr, December 9. The cause is said to be professional jealousy. The bullet penetrated the apex of the right lung.

**Election of Officers.**—The Chatham County Medical Society held its annual meeting at Savannah, January 6, and elected the following officers: President, Dr. J. Lawton Hiers; vice-presidents, Drs. George R. White and Ralph M. Thomson; recording secretary, Dr. Ralston Larrimore; corresponding secretary, Dr. James O. Baker; treasurer, Dr. William J. Williams, and librarian, Dr. Alpheus B. Simmons, all of Savannah.

### ILLINOIS.

**Physician Injured.**—Dr. Thomas B. Norvell, Peoria, was thrown from his sleigh, January 2, and injured his ankle.

**Smallpox in Twenty Counties.**—The State Board of Health reports the disease as present in 30 localities in 20 counties, with an aggregate of about 300 cases.

**Physicians Shun Advertising.**—Whiteside County Medical Society is reported to have adopted a resolution "requesting the newspapers to refrain from mentioning the names of physicians in connection with accidents or other cases where doctors are called."

**Quarantine of Lemont Raised.**—Lemont, which has been in strict quarantine since October 20, on account of epidemic smallpox, is now open to the world. None of the 380 cases was followed by death. The epidemic is now checked and the last of the affected are convalescent.

**State Board Election.**—At the annual meeting of the Illinois State Board of Health, held in Springfield, January 12, the following officers were re-elected: Dr. George W. Webster, Chicago, president; Dr. James A. Egan, Springfield, secretary, and Dr. James C. Sullivan, Cairo, treasurer.

**Send in Large Bills.**—The village health officer of Lemont, Dr. John A. Fitzpatrick, has rendered an account to the Board of County Commissioners of $5,820 for his services from October 20 to November 11. Dr. John J. Leahy presents his bill for $5,753. The president of the board asks, since each man asserts that he did the work, whether the county is liable for the payment of both bills.

**State Board Inspections.**—The inspectors who investigated the recent epidemic of typhoid fever at Canton discovered that the disease was caused by the use of water from a polluted well. The well was closed, and no original cases have since developed.——In Pontiac the water supply was found to be slightly polluted, and the local board was directed to order the removal of an intake which was found to be the source of the trouble.

#### Chicago.

**Superintendent from Minnesota.**—Presbyterian hospital has secured for superintendent Dr. Arthur B. Ancker, St. Paul, who has been for several years superintendent and physician and surgeon in charge of the City and County Hospital, St. Paul.

**Postmortem Award.**—A suit begun a long time ago by Dr. Emma N. Warne, against the estate of Francis T. Wheeler, for $50,000, has been decided in favor of the plaintiff, who is now dead, and the amount of the award, $12,500, has been paid to her estate.

**Deaths of the Week.**—During the week ended January 9, 516 deaths occurred, 88 less than the preceding week, and 109 less than the corresponding week of 1903. Pneumonia still leads with 114 deaths, next coming in order, tuberculosis, with 44, violence with 39, and Bright's disease with 38.

**Increased Longevity.**—The department of health draws the following deductions from the statistics of deaths in Chicago last year:

> The aggregate ages of the 28,353 decedents of 1903—exclusive of the theater-fire victims, not yet reported to the department—total 910,982 years, or an average of 32.1 years each. In 1892 the average was 22.6 years each, in 1882, 19.5; in 1872, 15.2. These figures show an increase in the average duration of human life in Chicago in less than a single generation—thirty-one years—of 111 per cent., or of more than double in 1903 that of 1872. In 1903 the average age at death was 42 per cent. greater than in 1892; 60 per cent. greater than in 1882, and, as already said, 111 per cent. greater than in 1872.

**Three Chicago Colleges Debarred.**—The Wisconsin Board of Medical Examiners decided, January 12, not to accept as evidence of ample medical training the diplomas of Harvey Medical College, National Medical University and Jenner Medical College, all of Chicago. The ground for the action is stated to be that the courses of study in those institutions do not come up to the standard adopted as the minimum by the Wisconsin board. Other schools that are deficient are to be removed from the accredited list. The board is also about to prosecute a number of unqualified practitioners in the state. The president of Harvey Medical College is reported in the Chicago *Tribune*, January 13, to have stated in an interview in defense of the graduates of that college:

> In the ten years of our existence, among the hundred graduates we have sent out, only two have failed to pass the state examinations creditably, and those two men both failed in Wisconsin. They went through Harvey, however, before we had our modern equipment.

We are afraid that the president of Harvey College was misquoted, or possibly she has not followed the results in all states. From our records we find that outside of Illinois, only 8 Harvey graduates have appeared before the various licensing boards whose records we have published, and of these 4 passed and 4 failed, a percentage of failures of 50 per cent. The failures were as follows, one in Wisconsin, January, 1902, and one in April, 1902; one in Idaho, in April, 1903, and one in Wisconsin in July, 1903. All of these failures were of the class of 1901. It would seem that the Harvey graduates as a rule stay in Illinois, for our records show that the Illinois board has licensed from July, 1902, to July, 1903, inclusive, 34 holding diplomas of that school, and rejected none.

### INDIANA.

**Measles Epidemic.**—At the Indiana Institution for the Deaf, Indianapolis, 81 out of the 340 inmates are ill with the disease.——The epidemic in Norwood is unabated, 63, or about one-eighth of the population, are ill.——At St. Joseph's Orphan Asylum, La Fayette, 87 out of 157 are ill with measles.——Up to January 6, 244 cases had been reported to the Indianapolis Board of Health.——At a school in Trafalgar, 18 out of 20 pupils have the disease.

**Personal.**—The venerable Dr. William H. Wishard, who has practiced for 64 years in Marion County, was elected president of the Indianapolis Medical Society, January 5.——Dr. William Flynn, Marion, has been seriously ill with pneumonia.——Dr. Samuel Brown, New Bethel, is seriously ill.——Dr. Alembert W. Brayton, Indianapolis, has recovered from his recent illness.——Dr. Stanley W. Edwins, Elwood, is dangerously ill.——Dr. Isaac N. Trent, Muncie, has been elected second vice-president of the state medical society.

**Disease and Death in November.**—The monthly statistics of the State Board of Health show that bronchitis was the most prevalent disease in November, and tonsillitis the next prevalent. Pneumonia was more prevalent than in the same month last year, the deaths being 241 and 181 respectively. The total number of deaths reported was 2,518, an annual rate of 12.2 per 1,000. In the corresponding month last year 2,406 deaths were reported, which is a rate of 11.6 per 1,000. The city death rate during the month was 15.5, which is 3.3 higher than the state rate for the same month. In the corresponding month last year the rate was practically the same as this year. The country death rate is 10.4. In the corresponding month last year it was 9.7. In November 324 cases of smallpox occurred in 33 counties, with one death. It is a singular coincidence that exactly the same number of cases was reported in October, and also the same number of deaths. In the corresponding month last year, there were 441 cases, with two deaths, and 40 counties were invaded. The tuberculosis deaths numbered 279, a rate of 135.2 per 100,000. The same month last year the deaths numbered exactly the same, another remarkable coincidence. Of the total deaths from consumption, 146 were females and 133 males; 28 of the males were married and between the ages of 18 and 40, and they left 56 children under the age of 12; 60 of the females were married and between the ages of 18 and 40, and left 120 children under the age of 12. Typhoid fever caused 105 deaths. The death rate from this cause for the whole state was 50.9 per 100,000. The city rate was 447; the country rate 54.4. Pneumonia deaths numbered 241, a rate of 116.8 per 100,000. In the corresponding month last year the rate was 87.7. The disease prevailed very much more extensively in the cities than in the country, the rates being respectively: city, 179.1 per 100,000; country, 84.5. Pneumonia does not lead consumption as a cause of death in Indiana, and has only done so in one or two months in the last four years. The violence deaths numbered 163. Of the violent deaths 4 were murders, 27 suicides and the rest accidental; 9 of the suicides were females, and chose the following methods of self-destruction: Drowning, 1; morphin, 3; carbolic acid, 3; other poisons, 2. Some of the causes of accidental deaths were: Railroads, 23, 2 of them being females; burns and scalds, 27, 16 being females; fracture of skull 11, all males; fracture of femur or other bones, 11, 7 being females; accidents in mines, 3; electricity, 1; horses, 3, and explosions, 2.

## KENTUCKY.

**College Incorporated.**—The Louisville National Medical College Company, which conducts a medical college for colored students, has been reincorporated with a capital stock of $12,000.

**Acquitted.**—Dr. W. Dallas Richards, Dayton, accused of having violated a city ordinance by failing to report a case of diphtheria and to placard the house, has been acquitted after a trial by jury.

**Smallpox.**—There are six cases in and near Burgin.——Several severe cases are reported from Webster County.——On account of the prevalence of the disease in Hart County, grand and petit juries have been dismissed.

**Personal.**—Dr. Alexander Bailey, Flagfolk, has been appointed second assistant physician at the Eastern Asylum for the Insane, Lexington.——Dr. S. Scott Prather, Louisville, is seriously ill with typhoid fever.——Dr. James M. Holloway is critically ill with kidney disease at his home in Louisville.——Dr. Cleva C. Owens, Frankfort, has been appointed first assistant physician of the Central Asylum for the Insane, Lakeland.——Dr. James W. Hill, Bardstown, has been appointed superintendent of the State Institution for Feeble-Minded Children, Frankfort.——Dr. J. R. M. Dillon, Paducah, has moved to New Orleans.

## LOUISIANA.

**Quarantine Laws.**—The State Board of Health met yesterday to consider requirements for land quarantine as a protection against the importation of yellow fever from western sources of contamination. No rules will go into effect until after a conference with the health authorities of Texas.

**New Orleans Pasteur Institute.**—The organization of the Pasteur Institute has been completed and the institute was formally turned over to Charity Hospital, January 4. It is now ready for the free treatment of every citizen of the state suffering or supposed to be suffering from this disease.

**In Favor of Tulane.**—The Louisiana Supreme Court has decided in favor of Tulane University the first and most important of two contests to the Hutchinson will. Eight hundred thousand dollars was left to the university to be used for its medical department for specified purposes. The first contest was as to the validity of the will and the second was as to whether the university could act as trustee for one of its departments. The second contest on the decision has not yet been rendered.

**Change of Meeting-Place.**—The Louisiana State Medical Society has changed its meeting place for 1904 to New Orleans. The remarkable increase in the size and activity of the state society promises such an unusually large meeting that those in charge of affairs at Lafayette feared that it would be impossible for them to accommodate properly the large number expected. The Orleans Parish Medical Society immediately extended a cordial invitation, and is vigorously pushing preparations for the largest and most successful meeting the state society has ever had.

## MARYLAND.

**Personal.**—Dr. Josiah S. Bowen, Mt. Washington, sailed for Europe, January 2.

**Smallpox.**—There is a case of smallpox at Mt. Pleasant, Frederick County, contracted, it is believed, from a man who died from the disease, December 31.——At Oakland there are 12 or more cases, all under strict quarantine.——A suspect is under quarantine at Sang Run.——At Loch Lynn Heights the quarantine was raised January 4.——It is reported that smallpox has broken out among the colored people near Ellicott City. The two physicians who saw the cases, some 20 or more, pronounced them respectively chicken-pox and smallpox; Dr. John S. Fulton, secretary of the State Board of Health, decided in favor of genuine smallpox.

### Baltimore.

**Deaths and Births.**—The week ended January 9 there were 235 deaths and 294 births reported. The annual death rate was 21.82 per 1,000, namely, for whites 18.66, for colored 39 per 1,000. Among causes of death were consumption 39, pneumonia 32, cancer 12, Bright's disease 10, diphtheria 5, and typhoid fever 3.

**Hospital Report.**—At the Presbyterian Eye, Ear and Throat Charity Hospital, 11,844 patients were treated during the year. One thousand dollars was expended out of the endowment fund for improvements. Of the cases treated 7,419 were eye cases, 2,042 ear cases, and 2,383 nose and throat. The daily average was 111. The treasurer reported a balance on hand of $1,528. Dr. Francis M. Chisolm was re-elected secretary of the board.

**Personal.**—Dr. Howard A. Kelly returned January 7 from a trip to Florida. His time there was spent in hunting and fishing. He attended a Spanish dinner given by the physicians of Tampa.——Dr. John B. Deaver, Philadelphia, will deliver the annual oration before the Medical and Chirurgical Faculty of Maryland in April.——Dr. Morris C. Robins, formerly associate professor of clinical medicine in the University of Maryland, has removed to Spokane, Wash.

**Tuberculosis Exposition.**—The Tuberculosis Exposition will open in McCoy Hall, Johns Hopkins University, January 25. The opening meeting will be held at 8 p. m. Prominent officials of the state and city will be present, including Governor Warfield and Mayor McLane. The orator of the evening will be Dr. Edward L. Trudeau, Saranac, N. Y. At 5 p. m. daily thereafter there will be lectures on various aspects of the tuberculosis problem, the lecturers being Dr. Mazyck P. Ravenel, Philadelphia; Dr. S. A. Knopf, New York; Mr. Frederick Hoffman, Newark, N. J.; Mr. Ernest Poole, New York; Dr. Vincent Y. Bowditch, Boston; Dr. George J. Adami, Montreal, and Dr. Lawrence Flick, Philadelphia.

**Report of Hospital for Insane.**—The Shepherd and Enoch Pratt Hospital for Mental and Nervous Diseases has issued its twelfth annual report. At this time 104 patients remained under care. There had been received new cases 120, and 114 discharged. Of the latter 20 were recovered and 48 improved. The trustees admitted all cases recommended by the staff as probably curable. About 15 per cent. of the 104 patients were treated free, and only 18 per cent. paid the average cost and over. With the exception of expenditures for needed buildings and repairs, the entire income was expended for the benefit of the hospital inmates. The laboratory has been enlarged and furnished with additional appliances, and the most advanced methods of investigation are there pursued. Of those admitted during the year, 58 were men and 62 women, of whom 19 men and 21 women were discharged unimproved, and one man and three women died.

## MASSACHUSETTS.

**Glanders on Increase.**—Sixty horses were quarantined in Cambridge during 1903 for glanders, and of these 54 were shot. This is an alarming increase in the prevalence of the disease.

***Deaths of 1903.***—Boston's death rate for 1903 is lower than usual, being only 17.70 per 1,000. The total number of deaths was 10,640, 343 less than in 1902. During the year 68 cases of smallpox with 13 deaths occurred in the city.

**Asphyxia for Criminals.**—Dr. Francis A. Harris, medical examiner for Boston, has written a letter to the public press advocating the substitution of some less "cruel and unusual" method of inflicting the death penalty than electrocution and suggesting the administration of carbon-monoxid to the criminal already in a narcotic sleep.

**Popular Medical Lectures.**—Public interest in things medical in Boston is shown in the course of lectures being given at the Lowell Institute on "Bacteriology" by Dr. Harold C. Ernst of Harvard Medical School, twice a week for four weeks; and by the lecture on "Consumption" before the Twentieth Century Club by Dr. S. Adolphus Knopf, New York City.

**Business Before Health.**—The Board of Health of Melrose has resigned, giving as a reason that they need more time for their own business. They have encountered sharp criticism since the smallpox epidemic last year, when they insisted on vaccination and the most thorough isolation and inspection. The board consisted of Drs. Paul H. Prorandie and John T. Timlin and Mr. J. H. Robinson.

**Brigham Bequests Benefit.**—The following hospitals among 21 charitable institutions received their annual gift of $1,000 from the Brigham Hospital Corporation: Massachusetts Charitable Eye and Ear Infirmary, Channing Home for Consumptive Women, Children's Hospital, Massachusetts Infant Asylum, Boston Home for Incurables, New England Hospital for Women and Children, and the Boston Lying-in Hospital.

**Children Thrive in New Home.**—The annual meeting of the corporation of the Convalescent Home of the Children's Hospital in Boston, which has been so crippled the past year by fire, while seeking the erection of a new building to accommodate 100, reports a marked success in its new building, where children receive the radical fresh-air treatment for tuberculosis. It is believed this is the first such building in the country, and the eight children there already show improvement in these few weeks.

**Insane Hospital Crowded.**—The fire at the Taunton Insane Hospital, where fortunately there was no loss of life, has called the attention of the public to the very crowded condition of the state insane hospitals. More than 8,500 people are cared for, and there is an increase of over 400 each year. There are sleeping accommodations for only about 7,400, so that 1,100 have to sleep on cots in corridors. In many buildings this is unsafe, hence the urgent demand of the officials this year for funds which will provide new buildings for at least 600 patients. During the past three years additional facilities have been provided by the state at Westboro for 350; at Taunton, 110; at Northampton, 200; at Danvers, 300; at Worcester, 150, and at Medfield, 170. All these hospitals are also establishing colonies which it is hoped will relieve the pressure somewhat. Beginning this year the state assumes the care of all the insane within its borders. This includes Boston, which city will, however, continue its own institutions and receive from the state a per capita amount. This means an annual additional expense to the state for care alone of $1,100,000.

## MISSOURI.

**Personal.**—Dr. Charles H. Wallace, St. Joseph, has been appointed chief surgeon of the St. Joseph and Grand Island Railway, vice Dr. Daniel Morton, resigned.——Dr. William W. Macfarlane, Mexico, has been re-elected surgeon-in-charge of the Ex-Confederate Home at Higginsville.——Dr. Asbury M. Crow, Kansas City, is critically ill.——Dr. Melvin W. Caster, Clayton, has been taken to the Missouri Baptist Sanitarium.——Dr. Harry E. Ferrel, St. Louis, assistant surgeon of the First Missouri Infantry, has resigned.——Dr. Edward C. Runge, superintendent of the St. Louis Insane Asylum, has resigned, to take effect February 1.

**Societies Elect Officers.**—Buchanan County Medical Society.—At the annual meeting held in St. Joseph, December 16, the following officers were elected: Dr. William T. Elam, president; Dr. John B. Reynolds, vice-president; Dr. Joseph J. Bansbach, treasurer; Dr. Charles W. Fassett, secretary; Dr. Thompson E. Potter, censor, and Dr. O. Beverly Campbell, delegate to the state association.

St. Louis County Medical Society.—At the annual meeting held in Clayton, December 9, Dr. Roy D. Moore, Central, was elected president; Dr. Howard Carter, Webster Groves, vice-president, and Dr. Harry G. Wyer, Kirkwood, secretary.

St. Louis Medical Society of Missouri.—The following officers were elected at the annual meeting, December 26: President, Dr. Benjamin M. Hypes; vice-president, Dr. Henry C. Dalton; recording secretary, Dr. T. Andrews Hopkins; corresponding secretary, Dr. Henry J. Scherck; treasurer, Dr. Robert M. King, and censors, Drs. Elisha H. Gregory, Robert C. Atkinson, and Paul Y. Tupper.

## NEW YORK.

**Compulsory Vaccination.**—The board of health of Jamestown required all children in public and private schools to be vaccinated before re-entering school after the Christmas vacation.

**Medical Mayors.**—Dr. Eugene Beach has been elected mayor of Gloversville. Dr. Beach is also a member of the State Board of Medical Examiners.——Dr. Edward F. Brush has been elected mayor of Mount Vernon.

**Drugs Are Poor.**—At the State Board of Pharmacy meeting the committee on adulteration and substitution of drugs reported that of 976 samples tested in the state 415 were found to be below the standard. The number of samples taken from the New York City drug stores was 871, of which 310 were found to be impure or substituted drugs.

**Smallpox Spreads.**—Smallpox continues to spread in Tonawanda, so that all the public schools are closed until further notice. The health board has also passed a resolution requesting the council to raise $4,000 to fight the disease.——In Buffalo the disease is well under control, and no new cases are reported.——Dr. A. C. Wilding has been directed to investigate the epidemic of smallpox in Chautauqua and Allegany counties.

**New Cocain Laws Needed.**—To check the cocain and morphin habit the State Board of Pharmacy has decided to recommend to the legislature the enactment of a law prohibiting the sale of these drugs on old prescriptions, or what are known as "repeaters." The sale is to be restricted to prescriptions of physicians and dentists, only one sale to be made on each prescription. The cocain habit is growing so rapidly that many pharmaceutic associations in the state have urged the importance of a state law to lessen, if not entirely stop, the sale of the drug to habitual users.

### Buffalo.

**New District Physician.**—Dr. George Westinghouse is now district physician, succeeding Dr. Eugene C. Waldorf.

**Senses Hospital Report.**—The twelfth annual report of the Charity Eye, Ear and Throat Hospital shows 1,507 new cases treated, and 7,611 old patients. Since the opening of the hospital 20,639 patients have been treated.

**State Hospital Report.**—The Buffalo State Hospital has issued its thirty-second annual report covering the year ended Sept. 30, 1902. The total number of patients treated during the fiscal year was 2,296, of which 1,059 were men and 1,237 women. It will be necessary to enlarge the hospital, as it is now filled to its utmost capacity.

### New York City.

**Personal.**—Dr. Samuel Alexander, professor of genito-urinary diseases, has obtained a leave of absence on account of sickness, and this year the lectures on the surgery of the genito-urinary tract will be given by Dr. Charles L. Gibson.——Dr. A. D. Davidow has moved to Florida, N. Y.

**Left Small Estate.**—It will be a great surprise to many who knew the late Dr. Cyrus Edson, and had knowledge of the extent of his medical practice, as well as the amount of other work that he did, to learn that his estate amounted to only $4,000. It is but another example of the common lack of business ability among medical men.

**Society Secures Permanent Quarters.**—The Eastern Medical Society of New York has engaged permanent quarters at 151 Clinton Street, New York. The building will offer every facility of the modern clubhouse, all of which will be open to the members. A reference library is one of the projected features. At the annual election, held recently, the following officers were elected: President, Dr. Louis J. Ladinski; vice-presidents, Drs. David Robinsohn and Tobias Berger; treasurer, Dr. Joseph Barsky; corresponding secretary, Dr. Abraham L. Wolbarst, and recording secretary, Dr. Abraham J. Ronginsky. Dr. Wolff Freudenthal was elected trustee for three years. The chairmen of the new committees are: Committee on ethics, Dr. Adolph A. Himowich; committee on house, Dr. Ephraim K. Browd; committee on admission, Dr. John A. Price, and committee on library, Dr. Charles Rayevsky.

## GENERAL.

**Military Hospitals Wanted.**—The Army Medical Department, in its schedule of desired appropriations amounting to $475,000, has the following: "A modern hospital of 100 beds to cost $100,000 at Fort Riley, a modern hospital of 24 beds to cost $30,000 at Fort Totten, N. Y., the enlargement of the hospitals at Fort Leavenworth, Kan., Fort Snelling, Minn., and Fort Sheridan, Ill., to cost respectively $45,000, $50,000 and $60,000.

**Typhoid Fever Committee.**—This committee of the conference which state health officers will hold with the U. S. Public Health and Marine Hospital Service has been appointed as follows: Dr. J. A. Egan, secretary of the Illinois State Board of Health, chairman; Dr. Samuel W. Abbott, State Board of Health of Massachusetts; Dr. William C. Woodward, health officer, District of Columbia; Dr. J. S. Fulton, State Board of Health of Maryland, and Dr. J. N. Hurty, State Board of Health of Indiana.

**The Tuberculosis Congress Situation.**—A meeting to discuss this situation will be held at 8:15 p. m., Jan. 28, 1904, at McCoy Hall, Johns Hopkins University, Baltimore, under the auspices of the Maryland Tuberculosis Commission. The meeting will be an informal one, and all American physicians and hygienists interested in the tuberculosis problem of this country are invited. The object of the meeting will be to form a national committee to represent the American medical profession at the International Congress on Tuberculosis to be held in Paris in 1905, and to discuss the announced Congress on Tuberculosis in St. Louis, and the other congress to be held in

Washington in 1905. It is to be hoped that the deliberations of this meeting will result in an understanding among all parties concerned, and that all individualism and partisanship will be supplanted by true love to humanity, by genuine scientific and practical methods, and by the highest professional motives. If it is the unanimous opinion of the medical profession that there should be an American Congress on Tuberculosis previous to the one which is to meet in Paris next year, it should be thoroughly representative and an honor to the American medical profession. Prof. Wm. H. Welch of Johns Hopkins has consented to preside. All communications relating to the meeting should be addressed to the secretary pro tem, Dr. H. Barton Jacobs, 11 Mount Vernon Place, Baltimore.

### CANADA.

**Grant to Victoria Order of Nurses.**—The Civic Treasury Board of St. John, N. B., has made a grant of $1,000 to the Victorian Order of Nurses. In connection with this order in St. John there are two nurses who last year made 3,000 visits to the homes of the poor. The nurses never attend cases except when asked for by a physician.

**Vancouver Physicians Want Health Officer.**—The Vancouver Medical Association has expressed itself as in favor of a city health officer who should give all his time to the duties of that office and who should be a competent bacteriologist and be provided with the necessary outfit for making examinations. A committee is investigating the conditions in other cities before the matter is taken to the city authorities.

**Montreal Health Statistics for 1903.**—In Montreal, for the past year, the deaths numbered 6,941 as against 6,275 for 1902. According to the government census of Montreal, with which the health officer does not agree, the death rate for 1903 would be 24.22 per 1,000. According to the calculations of Dr. Laberge, the rate should be 21 per 1,000. The death rate during the summer was larger than during other seasons, owing to the heavy mortality among children. The medical health officer hopes to reduce this in future years by a better understanding among young mothers as to the care of their offspring, a purer milk supply and greater attention to the feeding of children.

**The Physicians of New Brunswick and Vital Statistics.**—We have mentioned the proceedings against the physicians of St. John, N. B., for not reporting births to the registrar. The counsel for the medical practitioners gives it as his opinion that the law is unconstitutional, and that the sole and exclusive right to legislate with reference to vital and all other statistical matters belongs not to the local legislature but to the parliament of Canada. When these acts were first passed they did not compel physicians to report. At the last legislature an amendment was made compelling physicians to make these reports with a number of details, and in default of same, after five days, a fine of $20 or imprisonment in the county jail.

**Typhoid Epidemic in the Suburbs of Montreal.**—Typhoid fever is epidemic in Westmount, St. Henry and Ste. Cunegonde, suburbs of Montreal, and the one thing which these municipalities have in common, which is not shared by Montreal, is the water supply. The character of this has been criticised severely for the past two years. In St. Henri there are nearly 300 cases, and in the others over 200. Physicians and nurses are overcrowded, and hospitals are said to be unable to care for more patients. In the Royal Victoria Hospital, Montreal, there are 40 cases; in the Hotel Dieu, 20 cases; in the General, 28; Notre Dame, 12, the great majority of which have been brought in from the infected districts. At the request of the municipality of St. Henri the Provincial Board of Health will make an analysis of the water. Dr. Laberge of Montreal states that he has been informed that many of the cases of supposed typhoid are cases of la grippe.

### FOREIGN.

**Prizes Awarded by the Paris Academie des Sciences.**—Among the beneficiaries, the Paris professors, Albert Fournier and C. Richet received a $2,000 prize each, as also Prof. A. Monprofit of Angers. A woman, Miss Joteyko, received half of a prize of $260 for work on the nervous system. Two other prizes of about $200 were given to Arthus and V. Henri, and L. Damel for research in experimental physiology.

**Legacy to Provide Medical Attendance for the Rich.**—The will of a wealthy citizen of Montpellier, France, bequeathes a certain apartment building to the city authorities, the income from which is to be applied to the support of two young assistant professors—agrégés—who will treat all who apply, including and preferably the rich. The city authorities do not wish to undertake to supply medical care to the rich, and consequently do not know what to do with the bequest.

**A Prophylactic Novel.**—A French play was written a year or so ago which depicted the ravages of syphilis. It was entitled "Les Avariés" and, it is said, was written by Brieux in accordance with data furnished by Fournier. The public production of the play was prohibited by the censor, but this prohibition proved a great advertisement for the work, which was read extensively as the last sensation of the day, and was hailed by the profession as an important aid in the enlightenment of the public in regard to the dangers of venereal disease. A novel has recently been written along the same lines by Paul Bru, director of the Saint-Antoine Hospital at Paris. The theme is the sad fate of a bride infected by her husband's old and apparently insignificant gonorrhea. Pelvic lesions soon follow, compelling castration of the victim. In her horror at her unsexed condition she becomes insane. The title of the book is "L'Insexuée"—the Unsexed—and De Lavarenne recommends it as a touching work and a valuable contribution to the prophylaxis of venereal disease. In an editorial in the *Presse Médicale* he urges physicians to read the book so that they can commend it to their young male patients. The subject is handled as delicately as possible and appropriately for the general reader, but the possible evil consequences from an apparently trifling venereal disease are vividly portrayed. Brieux, the author of "Les Avariés," supplies a preface to the novel, and states in it that he considers gonorrhea as actually more dangerous than syphilis, as young men in their ignorance regard it so lightly.

### LONDON LETTER.

#### The Oyster Problem.

We have alluded recently in The Journal to outbreaks of typhoid fever from sewage-contaminated oysters in London and other places. As a result of the last oyster scare the Fishmongers Company has assumed the responsibility of examining the beds from which the London market is supplied, giving a certificate of health to oysters considered beyond reproach. These certificates have been accepted as guarantees by the consumer. Such certificates were given only after grave consideration and examination of the beds by experts appointed by the company, who in many cases ordered the closure of beds. The company is now indignant because Dr. Klein, the city bacteriologist, has condemned as sewage polluted oysters to which the company had given a certificate. Most wholesale dealers take the precaution of obtaining a certificate of purity from independent bacteriologists.

#### Typhoid Fever from Water-Cress.

An outbreak of typhoid fever, which took place in June, in Hackney, a metropolitan borough, has been traced by the health officer to water-cress. The outbreak occurred in two waves. The first consisted of 48 cases, almost all within a circle of one-third of a mile radius; the second, of 62 cases within a circle of half a mile radius. None of the usual sources of infection, such as water, milk, ice cream and shellfish, could be traced. But the health officer was struck with the fact that in 64 cases in the first wave and in 55 per cent. of the second the patients had eaten water-cress during the three weeks before illness. He, therefore, caused 17 samples of water-cress taken from places where the patients marketed to be examined. All showed sewage organisms, and a sample of water taken from beds near the metropolis where some of the cress was grown contained at least 50 colon bacilli per c.c. The health officer consequently suggests that an inquiry should be made as to the conditions under which water-cress is cultivated.

#### The Polyclinic.

At the fifth annual dinner of the members and friends of the Polyclinic the chairman, Mr. James Cantlie, said that the attendance at the institution had been large and annually increasing. A new hospital is necessary.

#### Boldness in the Treatment of Heart Disease.

At the West London Medico-Chirurgical Society Dr. Alexander Morison advocated boldness in the treatment of heart disease, especially in young adults and in those in the prime of life in whom there is no evidence of vascular degeneration and whose reserve of force is commensurate with their development. He recommended the tincture of digitalis or the combined tinctures of digitalis and strophanthus in doses of 15 to 30 m. every four hours until a definite effect is produced on the action, force and capacity of the dilated heart. This may require the continuous administration of the drug until 200 or 300 m. have been taken. But before beginning this treatment the patient must be prepared. In suitable cases the surcharged venous system must be relieved by venesection to 4 to 10 ounces, the edematous limbs drained by Southey's tubes or by incision, and effusion in the chest or abdomen removed as far as possible. For the treatment the constant supervision of skilled nurses is necessary.

## Correspondence.

### The Proposed National Bureau of Medicines and Foods.

SAN FRANCISCO, Jan. 7, 1904.

*To the Editor:*—Correspondence with the Joint Committee on a National Bureau of Medicines and Foods has developed several questions, one of which I should like to present through your columns for the purpose of eliciting suggestions. The question raised is as to the need for any such organization. There seems to be no dispute as to the truth of the fact that medicines and foods do not come up to fair standards of purity and identity. It is also agreed by all that many poor or worthless preparations of both pharmacopeial and extra-pharmacopeial preparations are on the market and are largely used. No one—especially no one in any way connected with medical journalism—has questioned the desirability of securing some means of determining the status of the host of mixtures, some ethical, some "proprietary," and some out-and-out nostrums, which now exist. The question at issue is as to the manner with which the situation shall be dealt. Can it be properly and successfully accomplished by legislation, either state or national? Some improvement can undoubtedly be secured through national legislation, insofar as the improvement of standard goods is concerned. But could national legislation, necessarily limited within the constitution, deal with more than a mere fraction of the problems that should be taken up and solved?

State legislation is less limited in possible scope, for it is not confined within the limits of the U. S. Constitution. Probably laws that would be within the limitations of the various state constitutions could be, theoretically, framed. But could they be made uniform, and could they be so framed as to cover the essential desiderata? And in the event that they could be framed and cover the ground properly, is it likely that such uniform laws could be passed in all the states? It is, on the one hand, contended that such state legislation should be striven for; on the other, that an immense amount of time and energy would necessarily be spent in this well-nigh Herculean task, and that if the laws could be passed, they would not be enforced. The committee is very desirous of securing as many opinions on these points as possible, to be considered in the preparation of its report.

Could legislation, either state or national, do anything to remedy the deplorable condition pointed out in a letter which I recently received from one of the best-posted physicians in the country, relative to the ethical status of present conditions? He says, in part: "In the good old days the medical profession stood as a unit in condemnation of all secrecy and monopoly in medicine. To-day, the professional spirit has waned to such a degree that the physician who sees advertised in his medical journal such things as ——, —— or —— does not stop to ask what place these things have in a scientific materia medica, but gives the new remedy a trial. It may be that the formula is published; it may be that there is a vague and prevaricating statement of the composition of the remedy, or it may be that a sphynx-like silence is maintained. So it has come to pass that largely the American physician of to-day is prescribing and is content to prescribe secret nostrums in place of remedies of known therapeutic properties." After reading his letter I read the Principles of Medical Ethics adopted by the American Medical Association, Chap. I, Art. I, Sec. 8, as follows: "It is equally derogatory to professional character for physicians to . . . . dispense or promote the use of secret medicines . . . ."

I voice not only my individual views, but also, I believe, the views of most, if not all, of the other members of the committee, when I say that we would like, if possible, to provide some means of bringing the profession back a little nearer to this section of the Principles of Ethics. We would like to be enlightened on this point by the views of others. Is it possible to do this by means of legislation, or in any way except by our own individual and collective effort? Can the objects sought be secured through the means of legislation? Suggestions or criticisms should be sent either to the chairman, Dr. H. H. Rusby, 776 DeGraw Avenue, Forest Hill, Newark, N. J., or to the undersigned, the secretary, at 31 Post Street, San Francisco.

PHILIP MILLS JONES, M.D.

### Technic in Treatment of Alcoholism.

MARINETTE, WIS., Jan. 5, 1904.

*To the Editor:*—Your editorial in THE JOURNAL, January 2, on "Technic in Treatment of Alcoholism," suggested by the paper of Dr. J. F. Kelley in the *Cleveland Medical Journal*, calls for a comment. It has been my custom for some time to stop the alcohol at once, and I have never been sorry for so doing.

A brief outline of treatment may be of interest: If, after an examination, the patient is found filled with liquor, he is given an emetic of apomorphia, 1/10 gr. will produce the desired results; then he is given a hot bath and put to bed, no restraint being used; the few cases in which a straight jacket or other appliances were used seemed to me to show that harm rather than good was produced. Alcohol in all its forms is stopped, and hot milk given every two hours, strychnia is given hypodermically to control the heart, and chloral, my favorite hypnotic in these cases, is sometimes used with morphia and hyoscin. The morphia, however, must be watched closely, as there are a number of patients whom it seems to aggravate. I usually order twenty grains of chloral every half hour until asleep; after the patient has rested six or eight hours, a saline cathartic is given; a hot bath, hot coffee and milk or beef tea are then given, for most of these cases have eaten little for several days. Then a capsicum mixture and the bromids are given freely.

Night and darkness are the favorite times for the demons that beset these people to appear, so it is well to have the room lighted when they are going to sleep. An attendant must be with the patient constantly, as in an absent moment he may do much harm. At night the chloral in hot milk is resumed, until the patient is asleep. With a liquid diet for a few days the patient will usually be able to help himself, with no desire, but rather an abhorrence, for any kind of stimulants. It seems to me that alcoholism is an acute poisoning, and I have never witnessed a death when withdrawal was immediate, but I am familiar with cases that died, in which alcohol was reduced gradually. The remark that delirium tremens is a result of withdrawal, rather than accumulation of alcohol, is true in accidents, surgery and pneumonia.

MAURICE DUANE BIRD, M.D.

### Trades Unionism Among Hospital Attendants.

SHERMAN, TEXAS, Jan. 6, 1904.

*To the Editor:*—In THE JOURNAL, January 2, are an editorial, "Trades Unionism Among Hospital Attendants," and a letter from Dr. V. H. Podstata, entitled "Trades Unionism Among Asylum Employes," a subject of more than ordinary importance. The statement of Dr. Podstata: "It is a well-known fact that the attendants and nurses, as well as other employes at Dunning, are under the protection of civil service, the protection being so strong as to absolutely prevent me from either hiring or discharging an employe," is a startling revelation. The forming of a union by the attendants and employes "organized on the same basis as a regular labor organization" is ominous. Hospitals for the insane can not be successfully conducted without a proper organization of officers and employes, all working together under an established set of rules. The superintendent, being responsible for the management, can not have any discipline or order when operating under such a state of affairs as now exists at Dunning. The attendants, nurses and other employes, once established in that institution, are independent of the superintendent, and obey his rules and instructions as suits their fancy.

It will be conceded that the insane are among the most unfortunate and helpless of afflicted human beings and that their condition should elicit the deepest sympathy from every one. Having been deprived of reason and of self-control, an insane person is liable to commit almost any act, and when such an act displeases a heartless attendant the patient is punished. Every year charges of cruelty to the unfortunate wards of some of these institutions are made, and in most instances they have some foundation. There can be no doubt that many acts of cruelty are committed in these asylums by brutes employed as attendants, and in many instances are not brought to light. In such a condition as we find at Dunning, almost any sort of brutal act by an impatient, quick-tempered nurse or employe may be committed, not in the dark nor behind locked doors in the ward, with the patient at his mercy, but in the very presence of the superintendent, who has no authority to discharge such employe; his hands are tied, he has no recourse, and yet he is held responsible by his superiors and by public opinion. It can easily be imagined that if such a state of affairs becomes general, the vast work and the splendid progress already made will be for naught, and we will be relegated to that unhappy period of inhuman treatment which existed when Pinel and Connelly came on the stage and began their great work of reform in this prolific field.

The position of asylum attendant, in a majority of these institutions, is more desirable and better paid, for the class of people thus employed, than any other they can command outside, and is much sought.

I am sorry to state that in many asylums the progress of excellent work is often interrupted by politics. False economy presented in a byplay at the footlights and viewed with approval by an admiring but duped constituency, often destroys the success of a bright promise. While many of our asylums are too large, with a population too numerous to permit the attainment of the greatest success, the improvement in asylum management and treatment in the last half century has been steady. But in truth there is much to be accomplished. I hope the crusade against such unhappy conditions as obtains at Dunning will be continued.

J. T. Wilson.

## Marriages.

Robert R. Berry, M.D., to Miss Sarah Palmer, both of Union, S. C., December 30.

Vinje Syver, M.D., to Miss Rebecca Halvorson, both of Henning, Minn., January 2.

John H. McCassy, M.D., to Miss Alva Bradstreet, both of Dayton, Ohio, January 6.

Karl Meltzer, M.D., to Miss Marie Ambrosius, both of the City of Mexico, December 30.

Arthur J. Herzig, M.D., to Miss Blanche Hamburger, both of New York City, December 30.

Charles Andrew Cooperrider, M.D., to Miss Helen Tippet, both of Columbus, Ohio, January 5.

B. Frank Barnes, M.D., Newark, Ohio, to Miss Olive Mabel Marsh of Shawnee, Ohio, January 6.

John H. Buschemeyer, M.D., to Miss Florence H. Byrne, both of Louisville, Ky., December 29.

Dudley Williams, M.D., Boston, to Miss Mary Isabel Jones of Wilmington, Del., January 2.

Clarence E. Beekley, M.D., Price Hill, Ohio, to Miss Louise Zugelter, at Sandusky, Ohio, January 5.

Irenaeus W. Rayburn, M.D., to Mrs. Elizabeth Scott, both of Kokomo, Ind., in Iowa, December 25.

Joseph F. Williams, M.D., Yellow Pine, Ala., to Miss Helen Rose McMain of Citronelle, Ala., December 30.

Sidney Lockhart Scott, M.D., U. S. Navy, to Miss Marian Legare Reeves of Washington, D. C., December 23.

J. R. Marmaduke Dillon, M.D., New Orleans, to Miss Laura Beckwith Lintner of Albany, N. Y., January 5.

Arthur Henry Stall, M.D., Johnson's Corners, Ohio, to Miss Edna Carrie Prange of Akron, Ohio, at Barberton, Ohio, December 24.

## Deaths.

**Hamilton Atchison West**, M.D., of Galveston, Texas, a member of the American Medical Association since 1892, and vice-president in 1898, died in New York City, December 31, aged 53 years. He was born in Kentucky in 1849, and spent his early life in the blue grass region. He studied medicine at Louisville and received his medical degree from the University of Louisville in 1872. After graduating he went to Texas and first located in Corsicana. In 1875 he became a resident of Galveston and soon became prominent as a practitioner and citizen. He was one of the original faculty of the Medical Department of the University of Texas, and until four years ago was professor of theory and practice of medicine in that institution. He possessed in a marked degree the power of imparting information to students and was extremely popular as an instructor. He made a special study of malaria, typhoid fever and yellow fever and his contributions to the literature on these subjects are authoritative. For twelve years he was secretary of the Texas State Medical Association, and at the time of the devastating flood in Galveston was made secretary of the board of health, and did noble work in that capacity. When the work of reorganization was inaugurated by the American Medical Association he took a deep interest in it, and to him is due the greatest credit for the reorganization of the medical profession of Texas. Dr. West had for a long time been suffering from nephritis, and in November he went to New York City for consultation as to the advisability of an operation, but such a measure was not considered wise. Dr. West rapidly declined and died December 31. He was buried in Galveston, January 4.

**Jacob H. Vastine**, M.D. Jefferson Medical College, Philadelphia, 1858, surgeon to the One Hundred and Thirtieth Pennsylvania Volunteer Infantry during the Civil War; a member of the Columbia Medical Society, the Pennsylvania State Medical Association and the American Medical Association, died at his home in Catawissa Pa., January 2, from Bright's disease, aged 68.

**Theophalis Gilliam Birchett**, M.D. University of Pennsylvania, Philadelphia, 1856, twice mayor of Vicksburg, Miss.; for several years superintendent of the Mississippi State Charity Hospital, Vicksburg, and once a member of the legislature, died suddenly at his home in Vicksburg, January 1, aged 68.

**Byron Hiram Daggett**, M.D. University of Buffalo, 1867, health physician of Buffalo for two terms; surgeon of the Seventy-fourth Infantry, N. G., N. Y., died at the Buffalo General Hospital, three days after an operation for the removal of gallstones, aged 61.

**Fred W. Keehl**, M.D. University of Iowa, Iowa City, 1897, a member of the county, district and state medical societies, and of the American Medical Association, died at his home in Waterloo, Iowa, January 1, from typhoid fever, after an illness of ten days.

**Gustavus Adolphus Haefner**, M.D. University of Maryland, Baltimore, 1867; a medical cadet in the Army during the Civil War; stationed at Navassa Island for 17 years, died at his home in Harlock, Md., January 3, after an illness of a year, aged 59.

**Anton Eidenbenz**, M.D. University of Giessen, Germany, 1846, of New York City, surgeon of the Eleventh New York Volunteer Infantry in the Civil War, died in St. Luke's Hospital, New York City, December 31, from pneumonia, aged 86.

**Milton A. Halsted**, M.D. Cleveland Homeopathic Medical College, 1861, surgeon of the Fifteenth New York Volunteer Cavalry in the Civil War, died at his home in Jacksonville, Ill., January 4, from pneumonia, following typhoid fever, aged 65.

**Robert McIntyre**, M.D. University of the Victoria College, Cobourg, Ont., 1862, for 30 years health officer of Hespeler, Ont., died suddenly at that place, January 4, from heart disease, while making a professional call, aged 66.

**John Scott Hughson**, M.D. Medical College of the State of South Carolina, Charleston, 1867, some-time mayor of Sumter, S. C., died at his home in that city, December 29, from heart disease, after a short illness, aged 63.

**William M. Ikeler**, M.D. University of Michigan, Ann Arbor, 1870, whose name was erroneously given as Skeler in The Journal, January 2, dropped dead at his home in Three Rivers, Mich., December 15.

**William H. Chappell**, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1874, was burned to death at his office in Oregon, Ill., January 5, aged 55. The cause of the fire is unknown.

**Daniel Voorhees Scott**, M.D. University of Louisville, 1894, secretary of the Clark County, Ind., Board of Health, died at his home in Jeffersonville, Ind., from gastritis, January 6, aged 32.

**Frank B. Powers**, M.D. University of Michigan, Ann Arbor, 1893, formerly of Lawrenceburg, Ky., died suddenly in his rooms at Racine, Wis., December 30, from heart disease, aged 33.

**Daniel Devine Cunningham**, M.D. University of Michigan, Ann Arbor, 1892, died at his home in Coldwater, Mich., January 4, from nervous collapse, after an illness of three days, aged 41.

**Fred A. Hemphill**, M.D. Hahnemann Medical College, Philadelphia, 1899, of Allegheny, Pa., died suddenly at Bisbee, Ariz., where he had gone in search of health, December 24, from heart disease.

**Theodore F. Sterling**, M.D. West Virginia, 1881, died at his home in Parkersburg, W. Va., December 29. He was surgeon of the First Virginia Volunteer Infantry during the Civil War.

**Edward Dolan**, M.D. Bellevue Hospital Medical College, 1893, died at his home in Worthington, Minn., January 2, from the effects of carbolic acid accidentally taken, aged 37.

**Henry J. Bower**, M.D. Jefferson Medical College, Philadelphia, 1862, died at his home in Myerstown, Pa., December 31, from diabetes, after an illness of 21 weeks, aged 62.

**Philip H. Grier**, M.D. University of Pennsylvania, for nine years mayor of Elizabeth, N. J., died at the New Jersey State Hospital, Trenton, January 2, aged 74.

**Adolph J. Lengel**, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1882, died at his home in Dallas, Texas, December 30, from apoplexy, aged 46.

**George K. McAdoo**, M.D. Western Pennsylvania Medical College, Pittsburg, 1892, died at his home in Butler, Pa., from typhoid fever, December 23, aged 37.

**William A. Clore**, M.D. Medical College of Ohio, Cincinnati, 1894, died suddenly at his home in Bullittsville, Ky., from heart disease, January 3, aged 34.

**E. J. Stilley**, M.D. Western Pennsylvania Medical College, Pittsburg, 1889, died at his home in Hope Church, Pa., January 3, after a short illness.

**Frank S. Jackson**, M.D. New York University, 1882, died at his home in Dunkirk, N. Y., January 2, from Bright's disease, after a short illness, aged 52.

**Archibald A. McDonald**, M.D. Cleveland Medical College, 1874, formerly of Florence and Rockvale, Colo., died at Sierro, N. M., recently, from septicemia.

**Silas J. Damon**, M.D. American Health College, Cincinnati, 1876, died at his home in Bridgeport, Conn., December 31, from diabetes, aged 58.

**Chester Smith**, M.D. Homeopathic Hospital College, Cleveland, 1859, died from paralysis at his home in Portland, Mich., January 2, aged 72.

**Laban S. Major**, M.D. Botanico-Medical School of Ohio, Cincinnati, 1848, died at his home in Austin, Ill., January 3, aged 81.

**John M. C. Damron**, M.D. Rush Medical College, Chicago, 1860, of Vienna, Ill., died at Hot Springs, Ark., January 2, aged 80.

**Joseph Hatton**, M.D. Medical College of Georgia, Augusta, 1853, died suddenly at his home in Grovetown, Ga., December 30.

**Edwin Freeman**, M.D. Eclectic Medical Institute, Cincinnati, 1856, died at his home in Cincinnati, January 4, aged 70.

**Joseph Papik**, M.D. Bennett College of Eclectic Medicine and Surgery, 1896, died at Chicago, Nov. 18, 1903, aged 29.

**W. F. Cherry**, M.D. University of Maryland, Baltimore, 1887, died at his home in Coakley, N. C., December 25.

**Russell R. Ramsey**, M.D. University of Nashville, 1872, died at his home in Cleveland, Tenn., December 31.

**William C. Bedford**, M.D. Chicago Medical College, 1874, died recently at his home in Tombstone, Ariz.

**William A. Cantrell**, M.D. University of Louisville, 1847, died recently at his home in Little Rock, Ark.

**John D. Walker**, M.D. Tulane University, New Orleans, 1884, of Florence, Miss., died recently.

**Frederick W. Urann**, M.D., Ohio, died at his home in Cleveland, January 1, aged 81.

**James L. Jones**, M.D., retired, died at his home in Denison, Texas, December 30.

## Miscellany.

**The Butler Typhoid Case.**—Judging from all the evidence in hand, Butler might almost as well have had no local board of health as the one which accepted the grave responsibilities of that position. In fact, perhaps, it would have been better off without than with the existing board, on which more or less reliance was placed, until it showed its utter incapacity. Finally, we wish to repeat our warning of a week ago, that hundreds of communities in this country are liable any day to be overwhelmed with the horrors of such an epidemic as that at Plymouth, or Ithaca, or Butler. These communities merely had to pay the penalties for impure water and lax sanitary administration which other communities equally neglectful have been fortunate enough to escape.—Soper in *Engineering News*.

**Treatment of Abscesses with Nitric Acid.**—M. Porosz of Budapest exclaims that if any one has once used a 2 to 5 per cent. solution of nitric acid in treatment of abscesses and buboes he will never treat them in any other way, as the effects are so satisfactory. He first evacuates the pus and then injects the solution with a urethral syringe as forcibly as possible. The abscess cavity becomes distended with the fluid which penetrates into every crevice and seems to stimulate the tissues in their work of repair after the germs in the lesion are killed by the action of the acid. In very deep buboes it may be necessary to repeat the injection daily, but healing is usually complete after two injections. The severest cases all healed in a week in his experience.—*Klinisch-therap. Wochft.*, X., No. 33, 1903.

**Phototherapy in Ophthalmology.**—H. Strebel of Munich has been applying light treatment to the eyes in some experimental research. The results indicate that the tissues of the eyes react in a different manner to the chemical rays from what is observed in the skin. The media of the eye allow the free passage of the ultra-violet rays, and he found it possible to induce a circumscribed inflammation in the retina. The iris responded to the chemical rays with hyperemia, moderate inflammation and pigmentation. It protects the tissues beneath, except when purposely excluded. He is convinced that conjunctivitis, blepharitis, eczematous keratitis and chalazion will prove amenable to phototherapy, and there is also a possibility that gonorrheal processes may be included in the list. He even suggests that direct sunlight may be utilized for tattooing the cornea. Besnamow has reported prompt healing of 5 cases of corneal ulcers after application of concentrated sunlight for two to five minutes daily, excluding the heat rays by passage through water. Strebel's iron light lamp was modified to adapt it to the eye for this research. The report of his experiments as read at the Naturforscher Congress is given in the *Klinisch-therap. Wochft.*, X, No. 45, 1903.

## Book Notices.

MODERN METHODS IN THE SURGERY OF PARALYSES. With Special Reference to Muscle-Grafting, Tendon-Transplantation and Arthrodesis. By A. H. Tubby, M.S. Lond., F.R.C.S. Eng., Surgeon to, and Lecturer on Clinical and Orthopedic Surgery and in Charge of the Orthopedic Department at Westminster Hospital; and Robert Jones, F.R.C.S.E., Honorary Surgeon to the Royal Southern Hospital, Liverpool. Illustrated by 93 Figures and 58 Cases. Cloth. Pp. 311. Price, $3.25. London: Macmillan & Co. New York: The Macmillan Co. 1903.

This little work covers the subject of the modern treatment of paralytic deformities fairly well and the well-known reputations of its authors will ensure it a favorable reception. The authors, as they say, have not given special attention to the older methods—which are all described in text-books on orthopedics—but limit those mentioned to muscle grafting, tendon transplantation and arthrodesis, which have worked an important change in the treatment of this class of cases. There are one or two important methods which they do not mention and undoubtedly did not favor, such, for example, as the surgical treatment of clubfoot advocated by Phelps, which has recently found an English adherent in Little, whose article was abstracted in The Journal, November 7, ¶8, p. 1169. The book is well illustrated and printed and is really a valuable addition to surgical literature.

Introduction to the Study of Malarial Diseases. By Dr. Reinhold Ruge, of the Imperial German Navy. Translated by P. Edgar, M.B., C. M. Edin., District Surgeon: Teluk Anson, F.M.S., and M. Eden Paul, M.D. Brux., M.R.C.S., L.R.C.P. Cloth. Pp. 137. Price, $2.75. London and New York: Rebman, Ltd. 1903.

This work is intended to provide, for ship surgeons and colonial physicians, a general résumé of the facts on malaria, its treatment, recognition, etc. It meets this purpose well. Our knowledge of malaria has greatly increased within the last few years, but this work is well up to date. The illustrations of the phases of the malarial parasites are good, as are also those of the malaria-bearing mosquitoes, and the graphic temperature curves throughout the text are also instructive. The staining methods are given in simple forms and the book is as a whole one that the physician in the tropics will find helpful. The English translation has been excellently done.

Fifteenth Edition of the Official Register and Directory of Physicians and Surgeons in the State of California. Cloth. Pp. 242. Revised and Published by the Medical Society of the State of California. Nov. 15, 1903. Price, $2.50.

The California Physicians' Directory is a well gotten up and arranged volume containing, beside a list of physicians, the medical law of California, fee bills, society statistics, etc., which such a work is supposed to contain. It is conveniently arranged alphabetically and by locality so that any physician in California can be immediately placed. It is one of the most complete and certainly one of the best appearing of the state volumes of its class. It is issued by the board of trustees of the state medical society and is sent free to members. To others its price is $2.50 per copy. It is well worth it to any physician or business man in the State of California or with extensive business interests there.

Radium and Other Radioactive Substances; Polonium, Actinium and Thorium, with a Consideration of Phosphorescent and Fluorescent Substances, the Properties and Applications of Selenium and the Treatment of Disease by the Ultra-violet Light. By William J. Hammer, Consulting Electrical Engineer. Cloth. Pp. 72. Price, $1.00. New York: D. Van Nostrand Co. 1903.

This book is based on a lecture delivered last spring before the American Institute of Electrical Engineers. It is a description of the fundamental principles connected with the phenomena and the properties, of radium, selenium and other radio-active substances. The author includes a description of a visit to the Finsen Institute at Copenhagen and a review of the work done there. His statements regarding the value of this method of treatment for certain conditions are exaggerated.

An Atlas of Human Anatomy. For Students and Physicians. By Carl Toldt, M.D., Professor of Anatomy in the University of Vienna. Assisted by Alois Dalla Rosa, M.D. Translated from the Third German Edition and Adapted to English and American and International Terminology. By M. Eden Paul, M.D. Brux., M.R.C.S., L.R.C.P. First Section. A. The Regions of the Human Body. B. Osteology. (Figures 1 to 377 and Index.) Cloth. Pp. 161. Price, $2.50. New York: Rebman Company. 1903.

This is a handsome volume. The work can be recommended as being perhaps as complete and accurate a handbook as is at present available. The author has endeavored to make the nomenclature thoroughly intelligible, using both Latin and English terms. The illustrations are excellent.

Mammalian Anatomy. With Special Reference to the Cat. By Alvin Davison, Ph.D., ex-Fellow of Princeton University. With Over 100 Illustrations, Made by W. H. Reese, A.M., from the Author's Dissections. Cloth. Pp. 250. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1903.

The common cat is the most available animal for the anatomy student in biology. As there are plenty of cats and as their number has to be frequently curtailed they afford ample dissection material for the genuine student in this department; it is, therefore, wise to select the cat as a typical illustration of the work of comparative mammalian anatomy. Dr. Davison has given us a convenient text-book which will be of service to students.

A Manual of Hygiene and Sanitation. By Seneca Egbert, M.D., Professor of Hygiene in the Medico-Chirurgical College of Philadelphia. New Third Edition, Enlarged and Thoroughly Revised. With 86 Illustrations. Cloth. Pp. 467. Price, $2.25 net. Philadelphia and New York: Lea Brothers & Co.

This third edition of Egbert's well-known work should have a generally favorable acceptance, not merely by the profession, but also by a large portion of the non-professional public who are more or less interested in sanitary matters. It is one of the best popular statements of general hygienic principles that we have and deserves a wide circulation. The present edition has been revised and includes some recent data as shown by the latest statistics, though in the main it is much like the previous editions and has not been specially enlarged.

A Surgical Handbook. For the Use of Students, Practitioners, House Surgeons and Dressers. By Francis M. Caird, M.B., F.R.C.S. Edin., Assistant Surgeon, Royal Infirmary, Edinburgh, and Charles W. Cathcart, M.B., F.R.C.S. Eng. and Edin., Surgeon, Royal Infirmary, Edinburgh. With Very Numerous Illustrations. Twelfth Edition. Morocco. Pp. 323. Price, $2.75. London: Charles Griffin & Co., Ltd. Chicago: W. T. Keener & Co. 1903.

This book contains a surprising amount of information, considering the fact that it is pocket size. The illustrations are abundant, especially those on fractures and other emergency surgery, for which the book may be chiefly recommended. An unusual addition to a work on surgery is the series of recipes for food for the sick.

Modern Surgery. General and Operative. By John Chalmers DaCosta, M.D., Professor of the Principles of Surgery and of Clinical Surgery in the Jefferson Medical College, Philadelphia. With Over 700 Illustrations, Some in Colors. Cloth. Pp. 1099. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The fourth edition of Dr. Da Costa's surgery has been revised and much new matter added. Modern methods are pretty thoroughly included, thus bringing it thoroughly up to date.

# Association News.

Place of Session of the American Medical Association for 1905.—Attention is called to the action taken at the last session of the American Medical Association to the effect that any city wishing to invite the Association to meet at that place should present the invitation, together with all available facts concerning hotel accommodations, number and seating capacity of halls available for section meetings, intramural means of transportation, railroad facilities, etc., at least three months before the annual session of the preceding year. In accordance with the above, it is hoped that those cities which desire the Association in 1905 will send their invitations, with all information possible, on or before March 1, 1904.

M. L. Harris, M.D.,
Chairman Committee on Place of Session and Transportation,
100 State Street, Chicago.

# State Boards of Registration.

## COMING EXAMINATIONS.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

New York State Board of Regents, at New York, Albany, Syracuse and Buffalo, Jan. 26-29. Secretary, James Russell Parsons, State Capitol, Albany.

Nebraska State Board of Health, State House, Lincoln, Neb., Feb. 10-11. Secretary, George H. Brash, M.D., Beatrice.

Kansas Board of Medical Examiners, State House, Topeka, Feb. 12. Secretary, O. F. Lewis, M.D., Hepler.

Massachusetts Report.—Dr. Edward B. Harvey, Boston, secretary of the Board of Registration in Medicine for the State of Massachusetts, reports the written examinations held at Boston, Nov. 10-11, 1903, as follows: Subjects, 9; questions, 60; percentage required, 70; candidates, 59; passed, 50; failed, 9.

PASSED.

College of Physicians and Surgeons, Boston, (1903) 75, 70.5, 70.
Boston University, (1903) 70.3, 75.6, 79.5, 79.8.
Baltimore Medical School, (1903) 70, 78.5, 71.1.
Tufts Medical School, (1903) 71.1, 71.4, 10.1.
College of Physicians and Surgeons, New York, (1903) 72.3, 82.4.
College of Physicians and Surgeons, Baltimore, (1903) 71.5, 78.8.

Harvard Medical School, (1901) 70.6, 78, 80.5, (1902) 73.3, 75.5, 73.6, (1903) 75.5, 83.7, 76.5, 74, 77.5.
University of Michigan, (1903) 75.4, (1901) 74.8.
University of New York, (1881) 70.3, (1880) 70.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| University of Louisville | (1901) | 70.5 |
| Southern Homeopathic College | (1903) | 70.0 |
| University of Naples | (1900) | 82.1 |
| Jefferson Medical College | (1903) | 71.8 |
| Imperial Alexanderian University, Finland | (1896) | 78.3 |
| Johns Hopkins Medical School | (1900) | 80.0 |
| Maryland Medical College | (1901) | 76.5 |

# The Public Service.

## Army Changes.

Memorandum of changes of stations and duties of medical officers for the week ending Jan. 9, 1904:

Kulp, John S., asst.-surgeon, relieved from duty at Fort McDowell, Cal., and ordered to assume the duties of attending surgeon and examiner of recruits at Philadelphia.

Kieffer, Charles F., asst.-surgeon, relieved from duty as attending surgeon and examiner of recruits, to take effect January 1, and will proceed to Fort D. A. Russell, Wyo., for duty.

Bushnell, Geo. E., surgeon, detailed to represent the Medical Department of the Army at the Tuberculosis Exposition at Baltimore, Jan. 25 to 31, 1904.

Stiles, H. R., asst.-surgeon, paragraph 12, S. O. 110, War Department, directing him to proceed to San Francisco, is revoked.

De Shon, George D., asst.-surgeon, relieved from duty at Boston, to take effect February 1, and ordered to Fort Des Moines, Iowa, for duty.

Wales, P. G., surgeon, relieved from duty at Fort Assinniboine, Mont., and ordered to San Francisco, for transportation to Manila, P. I.

Richardson, Geo. H., asst.-surgeon, resignation took effect January 1.

Greenleaf, H. S., asst.-surgeon, promoted captain and asst.-surgeon, U. S. Army.

Johnson, R. W., surgeon, will, in addition to present duties in connection with the Louisiana Purchase Exposition, St. Louis, supervise the sanitary conditions on grounds until April 1, 1904.

Polhemus, A. S., surgeon, leave extended two months.

Long, Charles J., contract dental surgeon, now in the Philippines, has been granted three months' leave of absence, and permission to return to the United States by the Suez route.

Springwater, Samuel A., contract surgeon, now at Chicago on two months' leave of absence from the Division of the Philippines, has been granted an extension of one months' leave.

Enders, William J., contract surgeon, will go from Fort Delaware, Del., to Fort Morgan, Ala., for duty.

Stearns, Charles H., contract surgeon, now at Nevada, Mo., on two months' leave of absence, has been relieved from further duty in the Division of the Philippines, and ordered to Fort Monroe, Va., for duty.

## Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending January 9, 1904:

Beyer, H. G., surgeon, on completion of board duty in connection with barracks ordered to Boston for special temporary duty, and thence to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Peck, A. E., asst.-surgeon, ordered to the *Pensacola*.

Elmer, M. K., asst.-surgeon, detached from the *Pensacola* and ordered to the *Hancock*.

## Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the twenty-one days ended Jan. 7, 1904:

Mead, F. W., surgeon, granted leave of absence for one day, December 26.

White, J. H., surgeon, bureau letter granting leave of absence for five days from December 17, amended to read five days from December 19.

Magruder, G. M., surgeon, granted leave of absence for two days from December 30.

Wertenbaker, C. P., Geddings, H. D., and Perry, J. C., P. A. surgeons, to report to chairman of examining board at Washington, D. C., January 18, for examination to determine their fitness for promotion to the grade of surgeon.

Rosenau, M. J., P. A. surgeon, detailed to represent the service at the meeting of the Society of American Bacterioologists at Philadelphia, December 29 and 30.

Wickes, H. W., P. A. surgeon, granted leave of absence for fifteen days from December 24.

Von Ezdorf, R. H., P. A. surgeon, to report to director of Hygienic Laboratory for temporary duty December 21, to proceed to the City of Mexico for special temporary duty December 31.

Foster, M. H., P. A. surgeon, granted leave of absence for four days from January 5.

Richardson, T. F., asst.-surgeon, granted leave of absence for one month from January 1.

Fox, Carroll, asst.-surgeon, granted leave of absence for five days from October 31, under paragraph 191 of the regulations.

McClintic, T. B., asst.-surgeon, granted leave of absence for seven days from December 26, under paragraph 191 of the regulations.

Francis, Edward, asst-surgeon, to report to the director of the Hygienic Laboratory for duty.

Stimson, A. M., asst.-surgeon, granted extension of leave of absence for two days from December 15.

Ward, W. K., asst.-surgeon, granted leave of absence for one day, December 17, under paragraph 191 of the regulations.

Smith, F. C., asst.-surgeon, relieved from duty at Immigration Depot, New York, and directed to proceed to Detroit and report to medical officer in command for duty and assignment to quarters.

Steger, E. M., asst.-surgeon, to proceed to Clarksburg, W. Va., for special temporary duty.

Gibson, L. P., A. A. surgeon, granted extension of leave of absence on account of sickness from November 20 to December 10.

Hume, Lea, A. A. surgeon, granted leave of absence for twelve days from December 19.

Tuttle, Jay, A. A. surgeon, granted leave of absence for ten days from December 21.

Brock, G. H., pharmacist, on being relieved from duty at Detroit, directed to proceed to Delaware Breakwater quarantine station and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist L. C. Spangler.

Goodman, F. S., pharmacist, relieved from temporary duty at Laredo, Texas, and directed to rejoin station at Norfolk, Va.

Allen, G. C., pharmacist, to proceed to Louisville, Ky., for temporary duty.

Iltis, G. W., pharmacist, relieved from duty at San Francisco and directed to proceed to Detroit and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist G. H. Brock.

Spangler, L. C., pharmacist, on being relieved from duty at Delaware Breakwater quarantine station, to proceed to Boston and report to medical officer in command for duty and assignment to quarters.

Bierman, C. H., pharmacist, granted leave of absence for eight days from December 22.

Irwin, Fairfax, surgeon, and Korn, W. A., asst.-surgeon, detailed as members of Revenue Cutter Service retiring board, to be convened at Philadelphia.

Rosenau, M. J., P. A. surgeon, four days' leave of absence from Jan. 1, 1904, under paragraph 189 of the regulations.

Amesse, J. W., asst.-surgeon, granted leave of absence on account of sickness for seven days.

Ashford, F. A., asst.-surgeon, relieved from duty at Chicago and directed to proceed to Milwaukee and assume temporary command of the service at that port.

### BOARDS CONVENED.

Board convened at the Marine Hospital, Stapleton, N. Y., January 4, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon Preston H. Ballhache, chairman. P. A. Surgeon A. C. Smith, recorder.

Board to meet at Washington, D. C., January 18, for the purpose of examining certain officers to determine their fitness for promotion to the grade of surgeon. Detail for the board: Asst.-Surgeon-General A. H. Glennan, chairman. Asst.-Surgeon-General L. L. Williams. Asst.-Surgeon-General G. T. Vaughan, recorder.

Board convened at the Marine Hospital, Chelsea, Mass., Jan. 11, 1904, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman. Asst.-Surgeon W. C. Rucker, recorder.

Board to meet at Washington, D. C., for the purpose of considering revision of medical books on contract and preparation of list of professional books, etc. *Detail* for the board: Asst.-Surgeon-General L. L. Williams, chairman. Asst.-Surgeon-General H. D. Geddings. Asst.-Surgeon A. J. McLaughlin, recorder.

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Jan. 8, 1904:

### SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 21-27, 7 cases.

Illinois: Chicago, Dec. 26-Jan. 2, 3 cases.

Iowa: Dubuque, Dec. 26-Jan. 2, 1 case.

Louisiana: New Orleans, Dec. 26-Jan. 2, 1 case.

Maine: Dec. 31, Athens, present; Brighton, present; Madawaska County, 39 cases.

Maryland: Baltimore, Dec. 26-Jan. 2, 1 case.

Michigan: Dec. 26-Jan. 2, Flint, 1 case; Port Huron, 2 cases

Missouri: St. Louis, Dec. 19-Jan. 2, 6 cases.

New Hampshire: Manchester, Dec. 26-Jan. 2, 1 case.

New Jersey: Dec. 26-Jan. 2, Camden, 5 cases; Trenton, 2 cases.

New York: Buffalo, Dec. 21-Jan. 2, 12 cases; New York, Dec. 26-Jan. 2, 1 case, 1 death.

Ohio: Dayton, Dec. 26-Jan. 2, 2 cases.

Pennsylvania: Dec. 26-Jan. 2, Altoona, 1 death at county hospital; Erie, 2 cases; McKeesport, 3 cases; Philadelphia, 74 cases, 11 deaths; Pittsburg, 17 cases, 4 deaths; Reading, 1 case; Johnstown, Dec. 19-Jan. 2, 4 cases, 1 death.

Tennessee: Dec. 26-Jan. 2, Memphis, 8 cases, 2 deaths; Nashville, 1 case.

Utah: Salt Lake City, Dec. 26-Jan. 2, 3 cases, all imported.

Wisconsin: Milwaukee, Dec. 26-Jan. 2, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Dec. 5-12, 21 cases.

Brazil: Pernambuco, Nov. 1-15, 20 cases; Rio de Janeiro, Nov. 29-Dec. 6, 58 cases, 50 deaths.

Great Britain: Dec. 12-19, Birmingham, 1 case; Liverpool, 1 case; London, 6 cases; Manchester, 4 cases; New Castle, 5 cases.

Italy: Catania, Dec. 10-17, 3 deaths.

Russia: Odessa, Dec. 5-12, 2 cases; Warsaw, Nov. 7-14, 10 deaths.

Turkey: Smyrna, Nov. 29-Dec. 13, 13 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Dec. 30-Jan. 2, 2 cases.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Nov. 22-Dec. 6, 1 case.

Ecuador: Guayaquil: Dec. 6-12, 1 death.

Mexico: Ciudad Victoria, Dec. 12-19, 3 cases, 2 deaths; Dec. 13-19, Merida, 6 cases; Tehuantepec, 1 case, 1 death.

PLAGUE.

Brazil: Rio de Janeiro, Nov. 29-Dec. 6, 27 cases, 22 deaths.

China: Hongkong, Nov. 21-27, 3 deaths.

Egypt: Nov. 28-Dec. 4, 3 cases, 3 deaths.

India: Bombay, Dec. 1-8, 51 deaths; Calcutta, Nov. 28-Dec. 5, 14 deaths; Karachi, Nov. 29-Dec. 6, 6 cases, 6 deaths; Madras, Nov. 28-Dec. 4, 1 death.

Japan: Yokohama, Nov. 21-28, 1 case, 1 death.

CHOLERA.

India: Calcutta, Nov. 28-Dec. 5, 42 cases; Madras, Nov. 20-Dec. 4, 3 deaths.

Turkey in Asia: Nov. 30, 89 cases.

## Medical Organization.

### California.

Stanislaus County Medical Society.—A meeting of the physicians of the county was held at Modesto, December 5, at which the first steps toward organization on the standard plan were taken. Dr. Benjamin F. Surrhyne was elected chairman, and Dr. George F. Bradbury secretary, both of Modesto.

Butte County Medical Society.—This society was organized on the standard plan at Chico, December 19, and the following officers were elected: Dr. Oscar Stansbury, Chico, president; Dr. Eli A. Kusel, Oroville, vice-president; Dr. D. H. Moulton, Chico, secretary and treasurer; Dr. Oscar Stansbury, Chico, delegate to the state society, and Dr. Buchanan Caldwell, Biggs, alternate.

Santa Cruz County Medical Society.—In response to an invitation from Dr. Phillip M. Jones, San Francisco, representing the state society, the physicians of the county met at Santa Cruz, December 22, and organized a county society on the standard plan, with the following officers: Dr. Exeter P. Vaux, Santa Cruz, president; Dr. Spencer C. Rodgers, Watsonville, vice-president; Dr. Saxon T. Pope, Watsonville, secretary; Dr. Ira C. Bush, Santa Cruz, treasurer; Drs. James F. Christal, Santa Cruz; William A. Phillips, Santa Cruz, and Nat. Green, Watsonville, censors; Dr. Saxon T. Pope, Watsonville, delegate to the state society, and Dr. Willis R. Congdon, Santa Cruz, alternate.

### Illinois.

Putnam County Medical Society.—Dr. William O. Ensign, Rutland, councilor for the Second District, met the physicians of the county at McNabb, November 28, and assisted them in organizing a county society on the standard plan, with Dr. Osker F. Taylor, Magnolia, president, and Dr. Edgar A. Hall, Florid, secretary.

### Indian Territory.

Pickens County, Chickasaw Nation Medical Society.—The physicians of this county have organized a medical society.

Indian Territory (Western District) Medical Association.—At the meeting held in Muskogee, December 9, the society decided to be governed by the rules of the American Medical Association.

### Indiana.

Kankakee Valley District Medical Association.—At the winter session of the Kankakee Valley Medical Society, held in Hammond, December 8, it was voted that the organization conform to the rules of the American Medical Association adopted by the Indiana State Medical Society. The following vice-presidents for counties in the district were appointed: Lake County, Dr. H. E. Sharrer, Hammond; Porter County, Dr. Joseph C. Carson, Valparaiso; La Porte County, Dr. Frederick A. McGrew, La Porte; St. Joseph County, Dr. Charles A. Daugherty, South Bend; Starke County, Dr. L. Dow Glazebrook, Knox; Marshall County, Dr. Novitas B. Aspinall, Plymouth; Newton County, Dr. Theodore E. Collier, Brook; Jasper County, the late Dr. Israel B. Washburn, Rensselaer; Pulaski County, Dr. George W. Thompson, Winamac; Fulton County, Dr. George E. Hoffman, Rochester; Cass County, Dr. Nelson W. Cady, Logansport, and Carroll County, Dr. William F. Sharrer, Delphi.

### Iowa.

Webster County Medical Society.—This society has endorsed the state society reorganization on the standard plan.

Muscatine County Medical Society.—At an informal meeting held at Muscatine, December 11, the society, after reading the new by-laws, with the clauses objected to by three county societies, agreed by mutual consent to stand by and uphold the state society.

Clinton County Medical Society.—At the annual meeting held in Clinton, January 5, Dr. George A. Smith was elected president; Dr. Herbert R. Sugg, vice-president, and Dr. E. L. Martindale, secretary and treasurer, all of Clinton. The society voted to incorporate, and postponed the discussion of the proposed affiliation with the state society until the April meeting.

Adair County Medical Society.—At a meeting of physicians held in Greenfield, December 17, a county society was formed on the standard plan, with the following officers: Dr. Thomas W. Mulhern, Greenfield, president; Dr. John E. Howe, Greenfield, vice-president; Dr. Pierre McDermid, Fontanelle, secretary, and Dr. James A. Harper, Jr., Greenfield, delegate to the state society.

Union County Medical Society.—Dr. Edward E. Dorr, Des Moines, councilor for the Seventh District, has organized this society, at Creston, on the standard plan, with the following officers: President, Dr. Moses B. Reed, Cromwell; vice-president, Dr. Benjamin F. Gillmore, Creston; secretary and treasurer, Dr. Joseph P. Claybaugh, Creston, and delegate to the state society, Dr. H. G. Lynch, Spaulding.

Plymouth County Medical Society.—The physicians of the county met at Lemars, December 12, and with the aid of Dr. Edward Hornibrook, Cherokee, councilor for the Eleventh District, organized a society on the standard plan, with the following officers; Dr. Milton W. Richey, Lemars, president; Dr. Alfred H. Jastrom, Jensen, vice-president; Dr. G. Henry Mainmen, Lemars, secretary; Dr. Howard J. Wright, Kingsley, treasurer, and Drs. L. W. Wuesthoff, Struble, Mary A. Breen, Lemars, and John H. Rippey, Kingsley, censors.

### Maryland.

Queen Anne County Medical Society.—The physicians of the county met at Centerville, December 9, and organized a county society, of which Dr. James Bordley was elected president, and Dr. James M. C. Cockran, secretary, both of Centerville.

Somerset County Medical Society.—Under the auspices of the Medical and Chirurgical Faculty of Maryland, represented by Drs. Henry O. Reik, Baltimore, and Brice W. Goldsborough, Cambridge, a county society was organized at Princess Anne, December 12, with a charter membership of 9. The following officers were elected: Dr. Charles W. Wainwright, Princess Anne, president; Dr. William F. Hall, Crisfield, vice-president; Dr. Martin W. Goldsborough, Princess Anne, secretary, and Dr. Ralph L. Hoyt, Oriole, treasurer.

Montgomery County Medical Society.—Dr. Thomas A. Ashby, Baltimore, met with the physicians of Montgomery County at Rockville, December 11, delivered an address and assisted in the organization of a county society on the standard plan, with the following officers: President, Dr. Roger Brooke, Sandy Springs; vice-president, Dr. Horace B. Haddox, Gaithersburg; secretary-treasurer, Dr. John L. Lewis, Bethesda, and censors, Drs. Edward Anderson, Rockville, W. Thawley Pratt, Potomac, and Elisha C. Etchison, Gaithersburg.

### Missouri.

Audrain County Medical Society.—This society has been chartered by the state association, with an initial membership of sixteen, and the following officers: Dr. Robert W. Berry, Young's Creek, president; Dr. Charles T. Varnon, Mexico, vice-president, and Dr. C. A. Bothwell, secretary.

Howell County Medical Association.—The physicians of the county met at West Plains recently and organized a county society, with the following officers: Dr. James C. B. Dixon, West Plains, president; Dr. Junius W. Bingham, Pottersville, vice-president; Dr. Henry C. Shuttee, West Plains, secretary, and Dr. Henry A. Thompson, Lanton, treasurer.

### Mississippi.

Newton County Medical Association.—Physicians of the county met at Newton, December 14, and organized a county society, all but six of the physicians of the county being present. Dr. G. H. McNeill, Newton, was elected president; Dr. S. Barto Henton, Decatur, vice-president, and Dr. A. Lee Monroe, Lawrence, secretary and treasurer. A committee, consisting of Drs. G. H. McNeill, Newton; John B. Bailey, Conshatta; A. Lee Monroe, Lawrence, W. S. Norris, Stamper; John S. Adams, Chunkey's Station, and I. W. Cooper, Newton, was appointed to draft a constitution and by-laws.

### North Carolina.

Wilkes County Medical Society.—The physicians of the county met at Wilkesboro, December 9, and organized a county society, with the following officers: Dr. John W. White, Wilkesboro, president; Dr. James M. Turner, Wilkesboro, vice-president, and Dr. M. V. Burrus, secretary and treasurer.

### Ohio.

Carroll County Medical Society.—This society adopted a new constitution and by-laws at its meeting in Carrollton, December 14. Dr. John R. Williams, Carrollton, was elected president, and Dr. James J. Hathaway, Carrollton, secretary and treasurer.

### Pennsylvania.

West Philadelphia Branch of the Philadelphia County Medical Society.—This society was organized December 26. Dr. Milton B. Hartzell was elected chairman, and Dr. Charles A. E. Codman, secretary.

### South Dakota.

South Dakota (Seventh District) Medical Society.—The organization of this society was perfected at a meeting of physicians at Sioux Falls, December 10. The following officers were elected: Dr. Stephen Olney, president; Dr. Arthur H. Tufts, vice-president; Dr. John R. Hawkins, secretary, and Dr. Cora W. Carpenter, treasurer, all of Sioux Falls.

### Wisconsin.

Rock County Medical Society.—This society was organized last month at Janesville on the standard plan, the following officers being elected: President, Dr. Ernest C. Helm, Beloit; vice-president, Dr. Quincy O. Sutherland, Janesville; secretary, Dr. George W. Fifield, Janesville; treasurer, Dr. Samuel B. Buckmaster, Janesville, and censors, Drs. Isaac Buckeridge, Beloit; John F. Pember, Janesville, and James Mills, Janesville.

Jefferson County Medical Society.—About twenty physicians of the county met at Jefferson, December 8, perfected the permanent organization of a county society, and elected the following officers: Dr. William W. Reed, Jefferson, president; Dr. William F. Whyte, Watertown, vice-president; Dr. C. E. Lauder, Johnson Cieek, secretary and treasurer, and Drs. Carl R. Feld, Watertown; William A. Engsberg, Lake Mills, and Urban P. Stair, Fort Atkinson, censors

## Society Proceedings.

### MEDICAL SOCIETY OF THE CITY AND COUNTY OF DENVER.

*Annual Meeting, held in Denver, January 5.*

Dr. H. W. McLauthlin read a "Memorial Paper on the Life of Dr. Whitehead," in which he pointed out the great services he rendered the medical profession of Denver as an anatomist, surgeon and sanitarian. Special attention was paid to Dr. Whitehead's operation for cleft palate and his invention of several ingenious instruments.

Dr. George B. Packard, in his presidential address, dwelt on the benefits of the reorganization of the state and county societies, and suggested that the society emulate the example of the St. Paul society in building up a medical library, and in striving to possess a home of its own.

#### New Officers.

These officers were elected: Dr. S. D. Hopkins, president; Dr. W. J. Rothwell, vice-president; Dr. E. J. Rothwell, treasurer; Dr. L. B. Lockard, recording secretary; censors: Drs. S. D. Van Meter, L. N. Macomber, I. B. Perkins, Edward Jackson, and J. M. Burns; delegates to state society: Drs. G. B. Packard, Clarence L. Wheaton and John Chaše. The following committee was appointed to consider the suggestion of the president in reference to a library and home: Drs. C. D. Spivak, J. M. Blaine, Edward Jackson, Donald Kennedy and L. B. Lockard.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

*Special Meeting, held Jan. 7, 1904.*

#### The Results of the Treatment of Congenital Hip Dislocation.

A special meeting was held at the Children's Hospital for the purpose of hearing the report of the orthopedic staff of the hospital signed by Drs. Edward H. Bradford, Robert W. Lovett, E. G. Brackett, John Dane and Augustus Thorndike on the treatment of congenital hip disease in children. A large number of physicians and surgeons who last year witnessed the operations of Dr. Adolf Lorenz were present on invitation to hear the first official report of the success of those operations. The report was a provisional one, and covered 138 cases treated in the hospital during the last twenty years. There has been a steady gain in the success of the surgeons. Thus, while in the period previous to 1896 all the 26 cases treated were failures, in 1896-1902 out of 54 cases treated 12 were successful, and only 13 are known failures; 1902 included those cases treated by Dr. Lorenz, and of 22 cases treated 11 were successful, 4 failures, 4 showed improvement, and 3 results are not known; 1903 was a distinct advance on this even, for 33 cases were treated and 24 are successful, 6 failures and 3 results unknown. This gain is attributed in great part to the use of the machine devised by Ralph W. Bartlett, a young Boston lawyer, for of the 24 successful cases 18 were manipulated by its aid. But one case was treated surgically by incision this last year, and that was unsuccessful. Of the six cases treated by Dr. Lorenz, five were successes, the sixth being a child 9 years old, for whom the surgeon did not expect success.

The report dealt with the great advance made in anatomic knowledge of the parts, to which the staff of the Children's Hospital have contributed much, and the aid to be derived from the use of the *x*-ray, which now makes accurate diagnosis possible, both before and after treatment.

In all the cases treated there has not been a single surgical disaster or fatality. The conclusions drawn are that congenital hip disease is curable. It should be treated in infancy or early childhood by manipulative methods, but even at advanced years, if less than 10, the manipulative or mechanical method should first be tried, and if unsuccessful, the surgical operation should follow. This can be performed to-day with greater hope of success because of the great increase in anatomic knowledge. The exact limits for the manipulative method can only be determined by time.

At the request of the staff a committee consisting of Drs. David W. Cheever, J. Collins Warren, Charles F. Painter of Boston, and Dr. V. P. Gibney of New York was appointed by the society to verify the data and pass on the conclusions of the report.

### SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Sixteenth Annual Session, held in Atlanta, Ga., Dec. 15-17, 1903.*

*(Concluded from page 118.)*

#### The Technic of the Vaginal Method.

Dr. J. Riddle Goffe, New York, said that in his own hands the scope of the operation was no longer confined, on the one hand, to simple puncture and drainage, nor limited, on the other, to the radical operation of hysterectomy. All the intermediate procedures that were called for by the many pathologic conditions found in a woman's pelvis found their most direct route through the vagina.

There were two vaginal incisions through which the pelvic cavity could be reached; one, posterior and the other anterior to the cervix. The latter afforded the greater facilities for operative procedures, and the one on which he depended almost exclusively. The posterior incision is frequently used in connection with it to secure drainage and in some cases for manipulation. The method lent itself to every form of conservative work on the uterus and its appendages that had been suggested in the trend of recent modern gynecology. The successful application of it required patience, experience and skill, but when once the profession had been convinced of its superiority he believed it would grow in favor.

### Tubercular Ostitis of the Knee.

Dr. A. R. Shands, Washington, D. C., said that the management of a case of white swelling could be embraced in the terms immobilization and protection in any and all stages of the disease. When it became necessary to incise and drain a joint, it should be done thoroughly and good drainage should be kept up just as long as there was any discharge. When the infection of the joint was due to an ostitis that was near the surface of the ends of the bone, often the diseased bone sloughed away, and when it could be easily located and curetted, most excellent results were obtained. The operation of excision of the knee should never be done in children except in extreme cases, and even then the author believed that amputation would be best, for an artificial leg is more useful than such a leg as a child would have after excision.

### The Differential Diagnosis of Syphilis and Cancer of the Vulva.

Dr. Barton Cooke Hirst, Philadelphia, reported the case of a woman, 28 years of age, single, who had never been pregnant. She denied ever having led an immoral life, and the possibility of venereal infection. Ten years ago she was operated on in the Pennsylvania Hospital for hemorrhoids and fissure in ano. The wound of the operation did not heal properly. More than a year ago the patient noticed an ulcerated condition of the vulva, and a short time afterward incontinence of feces, followed soon by incontinence of urine. For two years past there had been amenorrhea. On a specular and digital examination, a *fistula between the fossa navicularis and the rectum* was discovered. The whole urethra was gone; there were three little tubercles at the neck of the bladder, these being all that was left of it. The vagina above the neck of the bladder was perfectly healthy. The cervix was normal except that it was atrophic, as was the whole uterus. The case, at first sight, looked like an inoperable epithelioma of the vulva, and was pronounced to be so by one of the most experienced dermatologists in Philadelphia. But there was none of that extensive infiltration and elevation of the skin surface around the edges of the ulceration, such as was seen in an example of extensive epithelioma of the vulva, considerably advanced, but not yet inoperable. Moreover, numerous pieces of tissue from different places in the ulcerated area showed nothing characteristic of cancer. There was everywhere the most extensive round-cell infiltration and necrosis of tissue. The microscopic study, as well as the macroscopic appearance suggested syphilis in the ulcerated gummatous form. Accordingly the patient was put on specific treatment in spite of her negative history. The treatment was given up within a week, as the patient was severely ptyalized.

Lupus next suggested itself. On two separate occasions, under anesthesia, twelve or fifteen pieces of diseased tissue were removed for microscopic examination. No tubercles nor bacilli could be discovered anywhere. Inoculations in animals were negative. The urine contained no tubercle bacilli. The bladder itself was healthy. There was a response to the tuberculin test, but the woman had a patch of consolidation in the apex of one lung. Meanwhile the patient was given *x*-ray treatments every other day for eight to ten minutes. Within three weeks the external ulceration was healed. Two weeks later the rectovaginal fistula spontaneously closed under the continuance of the *x*-ray applications. Nothing remained of the original disease except the absence of the urethra and an elephantiasic condition of the labia majora. The former had been corrected by urethroplasty. He had not yet joined the new urethra to the opening in the bladder, so that the establishment of continence of urine was still doubtful, but he was quite hopeful of making the patient eventually entirely comfortable.

### Symposium on Appendicitis.

Dr. George R. Dean, Spartansburg, S. C., considered appendicitis a surgical disease, and said that when it was once discovered there was only one proposition to be made, namely, to urge operation at the earliest possible moment.

Dr. J. M. Baldy, Philadelphia, said that his experience had led him to differ with those gentlemen who held that appendicitis generated pelvic inflammatory disease, or that pelvic inflammatory disease caused appendicitis. The two diseases were rarely associated, and only then as a coincidence. He had not seen a case in which, having found pus in a fallopian tube, he had found pus in the involved vermiform appendix; nor had he found a perforating or gangrenous appendix in such a case. On the other hand, where he had found a perforated or gangrenous vermiform appendix, or one which contained pus, either in its cavity or enclosed in its walls, he had never noticed pus in a fallopian tube or ovary. Should he find such conditions, it would appear to him that the two diseases existed as a coincidence and independently of each other, as far as direct infection from one to the other was concerned.

Dr. I. S. Stone, Washington, D. C., said: First, one should consider every delayed case with anxiety lest there should be retroperitoneal infection. Second, one should be careful to give a guarded prognosis in every case of appendicitis ushered in by or complicated by chills or any symptoms of sepsis. Third, if operating in such cases, one should consider retroperitoneal infection as already started, and act accordingly. The discovery and proper treatment of such infection was as important as the usual intraperitoneal technic.

Dr. Robert T. Morris, New York, said that the surgeon could not do good work, particularly in abdominal surgery, if he began his work with incisions that were too short, but after one had acquired a certain amount of skill in technic he could return to the shorter incisions. With long incisions there is more shock; more adhesions; first, because the exposure of the peritoneum through a long incision excites greater inflammatory reaction, and, second, the longer the incision, the greater the danger of infection from the aerial bacteria.

### The Significance of and Management of Paralysis of the Bowel.

Dr. George S. Brown, Birmingham, Ala., expressed the view that paralysis of the bowel in the presence of inflammation of the peritoneum was to be regarded, not as a pathologic condition to be combated, but rather as Nature's way of allowing the plastic exudate to form adhesions, and confine the infection. He held that it was not the paralysis, but the overdistention of the bowel, that should be fought.

It seemed to him that if the Ochsner plan of treatment would tide over a patient with a gangrenous appendix, such a patient could have a much better chance if that appendix were removed, and to the Ochsner treatment were added the tight abdominal binder with water to relieve thirst and wash out the stomach, if there was vomiting, together with opium *ad libitum*, to relieve pain and keep down peristalsis.

In a total experience of 90 cases of appendicitis he had 66 pus cases, 24 of which had been treated by the plan of starvation, except as to water, prolonged irrigation of the stomach before leaving the table, a tight abdominal binder and opium. Eighteen of these patients had more or less diffuse peritonitis, and 12 of these were so severe that they had to be extensively disemboweled in order that adhesions could be broken up and septic material wiped away. Only 2 of these died. These might have recovered had they been tided over without operation, but as they were both *in extremis* at the time, probably the only thing saved would have been the reputation of the surgeon. Of 5 other deaths occurring in the 90 cases, 2 were due to subdiaphragmatic abscess rupturing into the lung, 1 to regurgitant vomiting, due to the presence of a large quantity of castor oil in the bowel which was not washed out, and 2 early cases where abscesses that had already set up a diffuse peritonitis were merely incised.

### Cases of Intestinal Obstruction Treated by Resection.

Dr. W. H. Doughty, Jr., Augusta, Ga., reported three successful cases of resection of intestine for obstruction due to gangrenous umbilical hernia, volvulus, and intussusception respectively. One of the cases was unique, so far as the author knew, in that the strangulated loop of intestine in the hernia was a part of a greater segment which had been strangulated by volvulus. It was likely that the descent of the herniated coil took place shortly after the occurrence of the volvulus, and its strangulation was occasioned by the congestion which followed the latter.

The almost invariable fatality which attended the operation he attributed to the toxemia that was induced by gangrene of the intussusceptum. In one case, however, which he outlined, in spite of the unmistakably gangrenous patches on the intussuscipiens and involving even the mesentery, the patient, though far from being in a satisfactory condition, stood the operation fairly well, rallied promptly from the depression which attended it, and recovered without interruption.

### Free Growths in the Tunica Vaginalis.

DR. EDWARD A. BALLOCH, Washington, D. C., reported the case of a colored boy, 16 years of age, who, during eight years, had had develop a painless enlargement in the upper part of the right of the scrotum. Examination showed a scrotum reaching nearly to the knees and measuring twenty-one inches in circumference at its largest point. Both testicles and both cords could be made out, and felt normal as to size, shape and consistence. There was no fluid in the scrotum, but a peculiar gelatinous, flabby feeling of the scrotal tissue. Three separate tumors were felt, freely movable in relation to cord, testis, and scrotal tissues.

The diagnosis of fibroid growths in the tunica vaginalis was based partly on the history of a slow, painless growth, and absence of ulceration and fistulæ, excluding cancer, syphilis and tuberculosis, and partly on the physical characteristics of the growths, together with a keloid behind the right ear which was interpreted as indicating a tendency to fibromatosis in the patient.

Operation showed the tunica greatly enlarged and thickened, and converted into a gelatinous mass. The upper tumor ran into the inguinal canal and was attached there by a pedicle. The other two showed no distinct points of attachment. The tumors weighed thirty-eight ounces, and the tunica twenty ounces.

The growths were soft fibromata, with areas of fatty and myxomatous degenerations. The testicle also showed areas of beginning myxomatous degeneration. It was concluded that the growths had their origin in the subserous connective tissue.

Examination of the literature showed but one case resembling the one reported, although there were several reports of minute fibrous growths on the tunic following hydrocele treated by the injection of iodin.

### Colloid Carcinoma of the Rectum with Excision by the Combined Vaginal and Inguinal Routes.

DR. J. HORACE WHITACRE, Cincinnati, Ohio, reported a case of colloid carcinoma which had developed as a hard, uniform thickening of the entire circumference of the rectum and about six inches in length. The great predominance of fibrous tissue, the uniform involvement of a long segment of the bowel, and the appearance of minute nodules resembling miliary tubercles in the primary tumor of the rectum all spoke for hyperplastic tuberculosis of the bowel. A third point worthy of mention was the exceedingly rapid development of the solidly carcinomatous ovarian tumors from half a dozen minute miliary metastases on the peritoneal surfaces of each. These tumors were friable and almost jellylike, as were all of the metastases, whereas the original tumor was as hard as cartilage.

### Resuscitation of Animals Apparently Dead.

DR. GEORGE W. CRILE, Cleveland, Ohio, read a short paper on this subject, giving a summary of experimental data. When asphyxia caused failure of the heart and respiration, vigorous artificial respiration usually restored their function when administered within a few seconds. It was effective in an inverse ratio to the time that had elapsed; it was rarely effective after forty seconds. Animals apparently dead for periods up to fifteen minutes were resuscitated by the combined effect of artificial respiration, rhythmic pressure on the heart, and the infusion of adrenalin. When the blood pressure had risen to thirty or more mm. Hg., the heart began to beat and the blood pressure was rapidly restored. The return of respiration was signaled by a short, almost imperceptible movement of the diaphragm, the respiratory action becoming gradually stronger and more frequent. The conjunctival reflex returned early. Some of the experiments failed on account of too great elevation of the adrenalin bottle; some on account of an overdose of adrenalin, several were only partially successful, owing to the great dilution of the adrenalin.

Experiments in which saline infusion was substituted for adrenalin, and which were unsuccessful, were promptly successful on adding adrenalin. In a patient with crushed skull, and whose heart had ceased beating for nine minutes, resuscitation of the heart for thirty-one minutes by this method was made. During the operation for the elevation of the depressed bone, the patient moved his head.

Another patient apparently dead from a severe crushing of the base of the skull was partially resuscitated twenty-four minutes after the apparent death. The proofs of the apparent death were absence of respiration, absence of heart sound on a stethoscopic auscultation, and as a final proof, on opening the jugular vein there was absolutely no circulation. In this case the blood pressure rose to 80 mm. at one time; voluntary respiration appeared. These evidences of vital action continued for thirty-four minutes.

### Officers for the Ensuing Year.

The following officers were elected: President, Dr. Floyd W. McRae, Atlanta, Ga.; vice-presidents, Drs. Geo. S. Brown, Birmingham, Ala., and J. Shelton Horsley, Richmond, Va.; treasurer, Dr. Charles M. Rosser, Dallas, Tex.; secretary, Dr. W. D. Haggard, Nashville, Tenn.

Birmingham, Ala., was selected as the place for holding the next annual meeting; time, Dec. 13-15, 1904.

Dr. John D. S. Davis, Birmingham, was selected as the chairman of the committee of arrangements.

### Monument to Dr. Davis.

The former action of the association in appropriating $2,000 to a memorial, consisting of a ward bearing the name of the association in the City Hospital of Birmingham, was rescinded, and in lieu thereof $2,000 was appropriated to the erection of a monument in Birmingham to the memory of Dr. W. E. B. Davis.

Other papers read were: "Diagnosis and Treatment of Gallstones," by Dr. Mack Rogers, Birmingham, Ala.; "Pneumatic Rubber Suit," by Dr. George W. Crile, Cleveland, Ohio; "Extrauterine Pregnancy," by Dr. T. J. Crofford, Memphis, Tenn.; "The Complications Encountered in the Surgical Treatment of the Testicle," by Dr. J. McFadden Gaston, Jr., Atlanta, Ga.; "Septic Thrombosis of the Femoral Vein Following Influenza," by Dr. D. F. Talley, Birmingham, Ala.; "Bilateral Diffuse Virginal Hypertrophy of the Breasts," by Dr. Gearge Ben. Johnston, Richmond, Va.; "Excision of the Psoas Magnus Muscle for Sarcoma," by Dr. George H. Noble, Atlanta, Ga.; "Pus Collections in the Pelvis," by Dr. C. N. Chavigny, New Orleans; "Five Recent Successful Laparotomies for Gunshot Wounds of Abdominal Viscera, Including One with Twenty-Eight Perforations of Intestines and Mesentery," by Dr. Robert W. Johnson, Baltimore.

---

## WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Thirteenth Annual Meeting, held at Denver, Dec. 28 and 29, 1903.*

*(Concluded from page 121.)*

### The Correction of Retrodisplacements of the Uterus.

DR. CHARLES W. OVIATT, Oshkosh, Wis., in a paper on this subject, showed a decided preference for the operation devised by Dr. George H. Noble of Atlanta, Ga., and described in THE JOURNAL, Aug. 9, 1902, p. 302.

He mentioned the following advantages of this operation: 1. Through the one incision any pelvic complication may be treated. 2. The operation utilizes the strongest part of the round ligament instead of its distal end. 3. The normal mobility of the uterus is not disturbed, and it is left in the pelvis where it belongs. 4. It causes no bladder irritation and no dragging because the traction on the ligaments is in the direction of their natural course.

### The Surgical Treatment of Goiter.

Dr. Charles H. Mayo, Rochester, Minn., in discussing this subject, said that it is probable that the lymphatic system acts as a duct to the thyroid, and a study of the function of the lymphatics would explain some factors in the etiology of diseases of this body.

The writer's experience was derived from 108 operations on thyroid tumors. Of these, there were 34 exophthalmic cases, with 6 deaths; 2 malignant, with 1 death; one large lingual thyroid. Two cases presented separated tumors of the pyramidal lobe. There were 71 cases of cystic, colloid, adenomatous and mixed types of goiter operated on, with one death, from pneumonia, on the eighth day. The recurrent laryngeal nerve was permanently injured once, and its function temporarily impaired several times.

He favored the Kocher collar incision, and if the capsule was found thickened over the local tumor, or whole gland, he advises enucleation by the Socin method. If the gland retained its general form, the largest lobe, usually the right, was extirpated, frequently leaving its posterior capsule to protect the laryngeal nerve. He preferred ether anesthesia, preceded by a hypodermic of morphia. Cocain had been used locally, where there was much tracheal disturbance or severe exophthalmic symptoms. He had usually observed some thyroidism one to three days after the operation.

### Intestinal Perforation in Typhoid Fever.

Dr. Byron B. Davis, Omaha, said that a very large number of the operations thus far reported for typhoid fever had not been done until general peritonitis had been fully established, and that 50 per cent. of recoveries did not seem unreasonable, if operation was done before the advent of the peritonitis. He stated that a small per cent. of the cases dying after operation did not die from the operation *per se* or the perforation, but as a result of the general typhoid infection, and thought such cases should not be charged against the operation.

Three cases were reported. The first was operated on the third day after the perforation symptoms arose, death following twenty-four hours later. The second was operated on twenty-six hours after perforation, and was followed by death in eighteen hours. The third was seen only seven hours after the perforation occurred, and there was so much doubt about the diagnosis that no operation was done. In the last case he could not help thinking that frequent estimation of the hemoglobin and a red blood cell count might have been of material value in differentiating between intestinal perforation and hemorrhage.

DISCUSSION.

Drs. E. J. A. Rogers, Denver, and Van Buren Knott, Sioux City, Iowa, both favored early operation in these cases, not waiting for a positive diagnosis.

Dr. James E. Moore, Minneapolis, Minn., mentioned a case in which operation was performed on the third day after perforation had taken place. General peritonitis was present, yet the patient recovered.

Dr. A. I. Bouffler, Chicago, was of the opinion that even in cases of doubt as to whether there was perforation or marked hemorrhage, operation was not necessarily fraught with serious danger.

Dr. C. H. Wallace, St. Joseph, Mo., recalled a case in which perforation had undoubtedly occurred. Operation was advised, but refused. An ice-bag was applied, peristalsis controlled, and, although the patient had pronounced shock, localized tenderness, etc., he recovered.

Dr. H. A. Sifton, Milwaukee, Wis., expressed the opinion that a careful examination would usually reveal perforation. The first case of perforation he operated on was in 1895, the diagnosis having been made within a few hours after perforation, and the operation resulted in a recovery. The second one occurred two or three years ago, the perforation in this case having been in the appendix. This case resulted fatally.

Dr. Charles E. Bowers, Wichita, Kan., said that perforation seldom, if ever, occurred higher than three feet above the ileocecal valve. One could shorten time very much by satisfying himself that it did not occur above that point.

Dr. H. G. Wetherill, Denver, called attention to the fact that erosion of the mucous membrane allowed transmigration of bacteria through the serous coat without actual perforation, and that this condition of things was, perhaps, more frequent than physicians had heretofore believed.

He thought the time was not far distant when the general practitioner would reach the conclusion which surgeons had pointed out, that a milk diet was not the best for typhoid fever patients.

### Surgical Treatment of Nephritis.

Dr. Alexander Hugh Ferguson, Chicago, made reference to the early history of this subject, and to the priority of the operation. He added three cases to those he had already published of renal decapsulation and puncture for active diffuse nephritis.

The indications for surgical treatment of this condition were pointed out at length, and the technic of the operation fully described.

The author thought that when the limitations of the operation were more clearly defined, and many of the extreme cases left alone, the mortality should not be more than 5 per cent. in the hands of experienced surgeons. He believed that the earlier an operation was performed in these cases, the less would be the fatality, and the greater the benefits.

### Multiple Loose Bodies in the Knee-Joint.

Dr. John P. Lord, Omaha, Neb., reported the case of a middle-aged man who had suffered from recurrent attacks of arthritis, the result of loose bodies in the knee joint. As loose bodies in the posterior part of the joint were the chief offenders, it was thought best to make a transverse division of the patella and incision of the lateral and crucial ligaments, as in an operation for resection. This permitted full command of the articulation. Great difficulty was encountered in removing two of the bodies located behind the condyles. The patella was wired. The capsular ligaments were sutured with chromicized gut. Drainage was instituted and an interrupted plaster dressing applied. Union was primary, and a good result secured, although motion was limited. After two months the degree of flexion amounted to about 30 per cent.

Attention was called to the necessity of delaying manipulation after this procedure for fear of retearing of the immature union of the ligaments, thus rekindling the arthritis. After a period of two months, however, active efforts were made to restore function, with greater success, although it was probable that full function could not be regained after such extensive surgical trauma of disarticulation.

### Median Perineal Prostatectomy.

Dr. George E. Goodfellow, San Francisco, had operated by the median perineal route in cases of hypertrophy of the prostate approximately seventy-three times, without any immediate mortality, so far as he was aware. All of these operations were done under spinal anesthesia. Instead of making an incision, as he had previously described, from the base of the scrotum to the margin of the anus, he now made an incision an inch in length above the perineal center, and through this opening he could enucleate the prostate with his forefinger. If it was necessary to enlarge the opening, he did so in the usual way. But through an ordinary incision he had enucleated a prostate weighing 7½ ounces. In no case had he failed to secure anesthesia when he had entered the canal. The needle was inserted between the second and third lumbar vertebræ.

### Complications and Sequelae of Prostatectomy.

Dr. James E. Moore, Minneapolis, stated that it was altogether too grave an operation to be resorted to as a routine treatment for enlarged prostate, and was only applicable to properly selected cases

The most frequent cause of death following this operation was uremia, consequently the most important preliminary examinations were those of the kidneys The next greatest danger was sepsis, and in the presence of an infected bladder it was an ever present one

The most positive indication for operation was very often a complicating cystitis, and it was for the relief of this complication that the various palliative measures were most frequently employed. The only satisfactory treatment for this complication was drainage, and this was best brought about by perineal prostatectomy. Stone was a frequent complication of enlarged prostate, and should always be sought for and removed during the operation The incision for a prostatectomy, when too extensive, caused various complications Hemorrhage was an occasional complication, but its dangers had doubtless been overestimated. A serious objection to the suprapubic operation was the extensive injury done to the bladder, while the most difficult problem connected with the perineal operation was how to avoid injury to the rectum

As sequelæ of prostatectomy, he mentioned impotence and incontinence or dribbling A communication between the urethra and the rectum was one of the sequelæ met with occasionally Epididymitis often followed prostatectomy, sometimes becoming so troublesome as to require the removal of the epididymis

The author believed some failures were bound to follow this important operation, but that it was destined to be one of the greatest boons modern surgery had to offer suffering mankind

### DISCUSSION

**Dr Alexander Hugh Ferguson** had operated on thirty one or two cases without a death, without complications or sequelæ, but since then in operating on these cases a death would occur after every few cases He had had four deaths, so far as he could determine, after having operated on forty cases In only one of these was death due to the operation *per se*

The discussion was further participated in by Drs C E Ruth, Charles A Powers, John P Lord, Archibald McLaren, William Jepson, D S Fairchild, Donald MacRae, none of whom gave as roseate a view of the results following prostatectomy by any particular route as had been reported by some surgeons

### Resection of Arteries and End-to-End Union. Experimental Research

**Dr O Beverly Campbell**, St Joseph, Mo, detailed forty experiments on animals, in which different methods of operating were adopted

His conclusions were as follows

1 The death of the endothelial cells following injury to arteries and the addition of cell death incident to the trauma inflicted from operative measures for the repair of the injury probably furnished the necessary nucleo-albumin needed for the production of the chemical process of coagulation of the blood

2 In the resection of arteries and in their suture in continuity, the suture should not penetrate the intima, as the additional death of endothelial cells incident to passing the suture and surrounding it from pressure necrosis might contribute to the coagulation of blood

3 The most rigid aseptic technic should be followed in surgical work on the arteries

### Surgical Treatment of Pulmonary Abscess.

**Dr Van Buren Knott**, Sioux City, Iowa, stated that the physical signs common to pulmonary abscess in many cases were alone not sufficient to render its exact localization possible, and while one might be satisfied in a given case that the lung contained an abscess, and from the usual methods of examination had decided as to its location, this point should be corroborated by the aspirator before proceeding with the operation Two cases of pulmonary abscess were reported

The treatment of these cases by other than surgical methods promises little, and as the complications of gangrene, empyema and bronchiectasis so seriously increased the mortality, even in the hands of the best operators, it would appear that a plea made for early operative relief of patients suffering with pulmonary abscess was not inconsistent with the facts

### The Anatomy and Physiology of the Peritoneum and Their Relation to the Treatment of Peritonitis.

**Dr Arthur E Hertzler**, Kansas City, Mo, said the stomata were declared to be artefacts, for the reason that they occurred only when the peritoneum was treated with a silver nitrate solution They did not appear when dilute solutions were injected into the peritoneal cavity of the living animal Attention was called to the fact that the universal reference to the deposit produced when a serous membrane was treated with silver as an albuminate of silver was an error No such substance existed What was formed was in all probability a silver chlorid produced by the action of the chlorin in the fluid with the mercury in the silver solution, producing the stable silver chlorid The peritoneum was covered by a layer of fat cells resting on a layer of elastic tissue Below this were the blood and lymph vessels Both systems always formed complete channels, and the lymph vessels never formed a connection with the peritoneal cavity In the process of absorption from the peritoneal cavity the fluid must pass between the endothelial cells lining the peritoneal cavity, through the elastic layer, and between the cells lining the blood vessels Whether the cells of each of these layers were united with the intercellular bridges could not be stated The absorption of .7 per cent NaCl solution took place more rapidly than any other solution Salt solutions of more than 1 per cent were absorbed more slowly Certain solutions caused a transudation instead of being absorbed Chief among these was formalin It was effective in a dilution of 1/10,000 Absorption was likewise lessened by the production of an artificial hydremia Normal NaCl solution might be used either by hypodermoclysis or per rectum, the former being the more rapid and certain

Applying these researches to the treatment of peritonitis, the fallacy of normal salt irrigations was insisted on By using this fluid the toxins were hurried into the circulation more rapidly The logical treatment was to employ those means which retarded absorption The production of an artificial hydremia might be accomplished either by the injection of the salt solution under the skin or per rectum Formalin in the strength indicated was safe, as had been previously determined by intravenous injections

### Cholecystitis, with Special Reference to Etiology and Diagnosis.

**Dr T E Potter**, St Joseph, Mo, after reviewing the subject, said that the most probable cause of infection of the gall bladder was through the blood of the portal system, and from this source we not only had the catarrhal and parenchymatous inflammations, with occasionally empyema, but sometimes malignancy caused by the presence of stones

Among the most prominent symptoms he mentioned tenderness immediately under the ninth intercostal cartilage, saying that this symptom was as valuable as tenderness in the region of McBurney's point in cases of appendicitis This tenderness might extend down for two or three inches To elicit it, one should press the fingers up under the ribs and require the patient to take a deep inspiration The patient would complain of pain, and if the fingers were held firmly, the act of inspiration was instantly stopped as though there had been a sudden attack of pleurisy

### The Treatment of Posterior Perforations of the Fixed Portions of the Duodenum

**Dr J E Summers, Jr**, Omaha, in a paper on this subject, said that retroperitoneal perforations of the duodenum were of such infrequent occurrence that little attention had been directed toward their treatment

He believed it was almost impossible for a gunshot wound of either the stomach or duodenum, which perforated both walls, to be limited to those organs Therefore, under such circumstances, in addition to the repair of any intraperitoneal organs involved, proper incisions must be made to provide for retroperitoneal drainage.

Dr. C. E. Ruth, Keokuk, Iowa, demonstrated the "Anatomic Treatment of Intracapsular Fractures of the Femoral Neck."

Dr. Donald McRea, Jr., Council Bluffs, Iowa, discussed "Portal Obstruction with Gastro-Intestinal Hemorrhage Following Operation."

Dr. William Jepson, Sioux City, Iowa, spoke of "Primary Carcinoma of the Spleen and Its Treatment by Splenectomy."

A paper by Dr. M. L. Harris, Chicago, on "The Use of Silver Foil to Prevent Adhesions in Brain Surgery," and one by Dr. H. G. Wetherill, Denver, on "Chronic Adhesive Sclerosing Peritonitis," will appear in The Journal.

### Election of Officers.

The following officers were elected: President, Dr. Charles H. Mayo, Rochester, Minn.; first vice-president, Dr. H. D. Niles, Salt Lake City, Utah; second vice-president, Dr. L. L. McArthur, Chicago; secretary-treasurer, Dr. B. B. Davis, Omaha, Neb.

Milwaukee, Wis., was selected as the place for holding the next annual meeting; time, Dec. 27 and 28, 1904.

---

## Therapeutics.

**[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]**

### Ergot of Rye in Treatment of Chorea.

According to an abstract in *Amer. Medicine*, Eustace Smith recommends very highly the use of ergot in the treatment of chorea. He states that there is too great fear of giving overdoses of this preparation. He does not hesitate to give it in dram (4.00) doses of the liquid extract to children seven or eight years of age and repeating it every three or four hours, continuing it for weeks if necessary, and twenty-drop doses (1.30) may be kept up for months. The pulse rate decreases fifteen or twenty beats, but no dilatation of the pupils, headache, nausea, abdominal pain or other unpleasant symptoms have been observed. He, in some cases, increases the dose to one and a half drams (6.00) if smaller doses prove ineffective. The addition of one to three minims (.06-.20) of liquor strychniæ (1 per cent.) to each dose of ergot seems to hasten the action of the ergot. He considers ergot, properly administered, to be a more reliable remedy than liquor potassii arsenitis. To obtain the results desired, the child should be kept in bed and the bowels kept freely open. This treatment should be kept up for some length of time after the symptoms have disappeared.

### Pilocarpin in Pneumonia.

According to E. Curtin, in *The Lancet*, pilocarpin is of great value in relieving the breathing and pleuritic pain in pneumonia. It seems also to hasten resolution. Its effects are so produced by exciting glandular secretion. He administers it in one tenth (.0065) grain doses of the nitrate which will not cause perspiration, but rarely fails to reduce the temperature within an hour. It may be repeated without any untoward effects. It stimulates the flow of saliva and cleans the tongue. The patient should be kept warm during the administration.

### Adrenalin Chlorid in Nasal Disturbances.

Adrenalin chlorid applied in the form of a spray or on pledgets of cotton, or in some cases dropped in with a medicine dropper, has been used extensively and to good advantage in nasal disturbance by S. G. Dobney, according to an abstract in *Med. Rev. of Reviews*. He has found it to be of great value in the treatment of hay fever, and other nasal neuroses producing transient obstruction due to swelling of the turbinates. Good results have also followed its use in acute rhinitis, thereby shortening the attack. It is superior to cocain, according to the author, in making a diagnosis between general hypertrophy of the nasal mucous membrane and a turgescence of the erectile tissues; in nasal operations, especially on the septum, its ability to check the hemorrhage is marvelous; however, in epistaxis it is of but little avail except when it consists of gentle oozing. He employs the following combination in the treatment of the foregoing conditions:

| | | | | |
|---|---|---|---|---|
| ℞. | Sol. adrenalin chloridi (1-100) | ℥i | 30 | |
| | Resorcini | | | |
| | Sodii chloridi, āā | gr. v | | 30 |
| | Aquæ destil. | ℥i | 30 | |

M. Sig.: To be used locally in the form of a spray or on pledgets of cotton.

Beaman Douglas recommends the following combination to be used in diseases of the nose and throat and for operative purposes:

| | | | | |
|---|---|---|---|---|
| ℞. | Cocainæ hydrochlor. | gr. v | | 30 |
| | Sodii chloridi | gr. x | | 65 |
| | Beta eucaine | gr. v | | 30 |
| | Ext. adrenalis ex sic. | gr. xxx | 2 | |
| | Aquæ | ℥i | 30 | |

Misce. Add the water to the dried suprarenal gland, filter and add the eucain and sodium chlorid and finally the cocain just before using. Sig.: Six minims to be injected beneath the membranes or applied locally on membranes by means of an applicator.

### Acute Eczema.

In the treatment of acute eczema, according to Bjorkman in *Merck's Archives*, if it is localized, a moist dressing should be applied containing 2 per cent. of boric acid or a dressing saturated with a solution of aluminum acetate (1-10).

If the eczema covers larger areas a dusting powder is of value, as follows:

| | | | | |
|---|---|---|---|---|
| ℞. | Zinci oxidi | | | |
| | Pulv. amyli, āā | ʒiiss | 10 | |
| | Talci venet. | ʒvi | 24 | |

M. Ft. pulvis. Sig.: To be used locally several times a day.

As a salve in these forms of acute eczema the following is of service:

| | | | | |
|---|---|---|---|---|
| ℞. | Bismuthi subnit. | ʒi | 4 | |
| | Lanolini | ʒii | 8 | |
| | Liq. petrolati q. s. ad | ℥ii | 60 | |

M. Ft. unguentum. Sig.: Apply locally; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi salicylici | gr. x | | 65 |
| | Zinci oxidi | | | |
| | Amyli, āā | ʒiiss | 10 | |
| | Liq. petrolati q. s. ad | ℥i | 30 | |

M. Ft. unguentum. Sig.: Apply locally.

If the pruritus is pronounced the following lotion containing carbolic acid will be of assistance in checking the itching:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi carbol. | gr. xx-xxv | 1.30-1 | 65 |
| | Aquæ rosæ | | | |
| | Aquæ destil, āā, ad | ℥iii | 90 | |

M. Ft. lotio. Sig.: To be externally applied; or as a salve the following to relieve the pruritus:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi salicylici | gr. vi | | 36 |
| | Menthol | gr. xi | | 70 |
| | Olei lini | | | |
| | Aq. calcis, āā, ad | ℥ii | 60 | |

M. Sig.: To be applied locally.

Another very effective combination is:

| | | | | |
|---|---|---|---|---|
| ℞. | Ichthyol. | | | |
| | Zinci oxidi, āā | ʒi | 4 | |
| | Lanolini | ʒiii | 12 | |
| | Liq. petrolati ad | ℥i | 30 | |

M. Ft. unguentum. Sig.: Apply locally.

### Erysipelas.

In *Med. Rev. of Reviews* Smolitcheff states that erysipelas can be treated locally with success by employing a remedy which is readily absorbed by the skin, and which is powerful enough to kill the active organism, the streptococcus, or at least to prevent its further activity. The remedy must at the same time, when taken up by the circulation, neutralize existing toxins and fortify the cells against their invasion and producing at the same time a leucocytosis. To fulfill such requirements he recommends the alcoholic tincture of iodin as a specific comparable to the effects of quinin in malaria. This preparation diminishes the swelling and pain and causes a drop in the temperature. The following combination is recommended by the author:

| | | | | |
|---|---|---|---|---|
| ℞. | Tinct. iodi | ʒvi | 24 | |
| | Olei camphoræ | | | |
| | Ichthyol., āā | ʒiii | 12 | |

M. Sig.: Shake and apply locally twice or three times a day.

### Glycerinate of Tannin in Burns.

According to an abstract in *Med. News*, the glycerinate of tannin has been found to be a most satisfactory preparation in the local treatment of burns. If the burns are of the second degree the vesicles should be punctured and the fluids removed, after which glycerin and tannin should be applied in 50 per cent. solution and covered by sterilized gauze and cotton. The solution should be applied several times a day without changing the gauze. Burns of third degree should be treated likewise. The good results are ascribed to the effects of the tannin on the diseased tissue, coagulating the albuminous substances and forming a protective coating, also the glycerin is an antiseptic.

### Otitis Media.

Patients suffering from acute otitis media must be kept indoors, according to *Kan. City Med. Rec.*, and given a purgative. Every two hours the temporal and mastoid regions and the ear should be covered with a compress dipped in a solution of sodium bicarbonate (60 parts to a 1,000) as hot as can be borne by the back of the hand. The whole may then be covered by a piece of oiled silk and held in place by a bandage. Previous to applying the compress three or four drops of the following solution may be dropped into the ear:

| | | | | |
|---|---|---|---|---|
| ℞. | Cocainæ hydrochlor. | gr. iss | | 09 |
| | Resorcini | gr. xii | | 75 |
| | Glycerini (neutral, sterilized) | ʒiiss | 10 | |

M. Sig.: Three or four drops instilled into the ear at every second dressing. Three or four times during the day the child should be placed on the bed with the head low and a few drops of the following combination instilled into each nostril:

| | | | | |
|---|---|---|---|---|
| ℞. | Menthol | gr. iv | | 25 |
| | Olei amygdalæ dulcis | ℥i | 30 | |

M. Sig.: To be introduced into the nares by means of a medicine dropper three times daily.

The mouth and pharynx should be thoroughly cleansed and irrigated three or four times daily with boiled water and introduced with a fountain syringe. If the pain does not cease within a day or two and the tympanum becomes bulged and red, paracentesis should be performed.

To serve as an astringent, the following is recommended by the author:

| | | | | |
|---|---|---|---|---|
| ℞. | Acetanilidi | | | |
| | Bismuthi subnit., āā | gr. xxiiss | 1 | 50 |
| | Ung. zinci oxidi | | | |
| | Ung. aq. rosæ, āā, ad | ℥i | 30 | |

M. Ft. unguentum. Sig.: Apply locally; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Alumnol | gr. xxiiss | 1 | 50 |
| | Ung. aq. rosæ ad | ℥i | 30 | |

M. Sig.: Apply locally.

Gerhard recommends the following in relieving the pain in acute otitis:

| | | | | |
|---|---|---|---|---|
| ℞. | Tinct. aconiti rad. | ʒiss | 6 | |
| | Glycerini (sterile) | ʒiiss | 10 | |

M. To be warmed and two or three drops instilled into the ear.

The following combination is also employed in relieving earache:

| | | | | |
|---|---|---|---|---|
| ℞. | Ichthyol | m. xv | 1 | |
| | Glycerini | | | |
| | Aquæ, āā | ʒii | 8 | |

M. Sig.: Warm and drop a few drops into the ear three times a day.

### Hypophosphites in the Treatment of Abscesses.

Sinclair Tousey, in *Annals of Gyn. and Ped.*, recommends the employment of hypophosphite of calcium, sodium and potassium in the prevention and treatment of abscess formations. He recommends it in that class in which there is no evidence of virulent infection, but simply a swelling of the subcutaneous tissue presenting well-marked fluctuation without redness or pain, such as may occur in the axillæ, perineum or about the neck. In the treatment of such conditions he recommends the following combination as being the most effective one:

| | | | | |
|---|---|---|---|---|
| ℞. | Calcii hypophos. | gr. v | | 30 |
| | Sodii hypophos. | gr. ii | | 12 |
| | Potass. hypophos. | gr. ii | | 12 |

M. Ft. capsula No. i. Sig.: One such three times a day.

If preferable the foregoing may be taken in the form of a syrup. This combination is preferable to those containing iron or strychnia.

### Therapy of Iron.

After studying a large number of cases, including the various forms of anemia and estimating the amount of hemoglobin and the number of corpuscles, Biernacki, in *Internat. Med. Mag.*, concludes that only in chlorosis is the administration of iron of real value. In other forms of anemia nothing can be expected from its use. He states, particularly, that the large number of neuropathic individuals, though pale and having the symptoms of anemia, show no real impoverishment of the blood and are injured rather than benefited by iron medication. Consequently he condemns the widespread custom of prescribing iron in cases of pallor without a proper examination of the blood. When indicated, as in chlorosis, iron should be given in large doses. No benefit can be expected from the use of the chalybeate waters.

---

## Medicolegal.

**Cause of Disease a Matter of Expert Opinion.**—The Supreme Court of Tennessee says, in Mayor and Aldermen of Knoxville vs. Klasing, that it is, and from the nature of the case must be, a matter of expert opinion as to what is the cause or origin of disease, and the testimony of physicians is the most reliable evidence that can be had on the subject.

**Damages Recoverable for Malpractice.**—The Supreme Court of South Dakota holds, in the malpractice case of Baxter vs. Campbell, that, there being nothing in the complaint or in the evidence from which malice might be presumed, an instruction authorizing the imposition of exemplary damages was seriously prejudicial to the physician sued. The writer of the opinion (Justice Fuller) says that, so far as his research has extended, the damages awarded in actions of malpractice are compensatory, and that the South Dakota statute provides for exemplary damages only as a means of punishment "when the defendant has been guilty of oppression, fraud or malice, actual or presumed." In order to justify the imputation of malice, within the rule of punitive damages, the injury must have been conceived in a spirit of mischief, and partake of a criminal or wanton nature. As exemplary damages are penal in character, and malice an ingredient of crime, no one should be adjudged to pay "smart money" without first being accused of something malicious, and given an opportunity to defend. When exemplary damages are predicated on malice, the party sued is entitled to know from the complaint what acts, omissions, or circumstances are relied on to constitute the gravamen of the charge, and the instructions of the court should be confined to the case as made by the evidence. Where both actual and exemplary damages are claimed, it has been considered necessary to allege each in a separate count or cause of action; but under the liberal practice of South Dakota a complaint is deemed sufficient to admit the proof when it reasonably appears from the recitals thereof that the damages alleged were maliciously occasioned. According to an elementary rule, instructions concerning exemplary damages, though properly alleged, should never be given unless evidence applicable thereto has been introduced.

**Constitutionality of Compulsory Vaccination Laws.**—The Second Appellate Division of the Supreme Court of New York says that, in the case of Viemeister vs. White, where the first-mentioned party sought to compel the admission of his child to a public school without the submission of the latter to vaccination as required by the state statute, attention was called to various provisions of the state constitution in an effort to establish a conflict between the statute and the fundamental law. First among these provisions, was one that, "The legislature shall provide for the maintenance and support of a system of free common schools, wherein all the children of this state may be educated." But the court is of the opinion that the constitution did not intend to change the practice and policy of the state in reference to the schools, but merely to insure a continuance and an extension of the privileges of citizens of the state, and that the legislature has a right to impose any reasonable regulations on this privilege which operate equally on all persons in the same class and under the same conditions. Continuing, the court says that it may be conceded that the legislature has no constitutional right to compel any person to submit to vaccination; but where the state grants a privilege it has the right to determine the conditions on which it may be enjoyed; has a right to regulate the privilege in the interests of the fullest enjoyment by all; and, so long as this regulation does not operate to deprive any member of the state of "any of the rights or privileges secured to any citizen thereof, unless by the law of the land or the judgment of his peers," there is no ground on which the statute may be declared null and void. The vice against which this constitutional limitation was directed was partial legislation—legislation which operated, not on the legislators and their immediate constituents, but on limited numbers of people. If the statute in question is not justified, if it is not wise or proper to impose the condition there named, it must be presumed that the legislature will in the future remedy the wrong. It can not be done by the courts. The statute violates no specific guaranty.

**Board of Health, Health Officer, Typhoid Fever, Etc.**—The Supreme Court of Michigan says, in the case of Cedar Creek Township vs. Board of Supervisors of Wexford County, that in the year 1900 sundry expenses were incurred by the health officer of the township. It did not appear that this was expressly authorized by the board of health, but the items were allowed by the said board of the township, and were then presented to the board of supervisors, which disallowed them. The claimants—i. e., the persons who furnished the services and other items—then presented them a second time to the board of health of the township, and they were allowed and paid by the township. Thereafter the township presented an itemized statement of the claims to the board of supervisors for payment, and they were again disallowed. The items presented were for expenses alleged to have been incurred in the care and treatment of typhoid fever cases within the township. The statute at the time provided that when any person should be infected with smallpox or other sickness dangerous to the public health, the board of health of the township where such person might be should make effectual provision in the manner in which they should judge best for the safety of the inhabitants by providing nurses and other assistance and necessaries, etc., which should be at the charge of the person himself or those liable for his support, if able; otherwise as a charge of the county; provided, that the health board should keep and render an itemized and separate statement of expenses incurred in so caring for each person. The health board, the Supreme Court says, has large discretionary powers, made necessary by the fact that it is an emergency board. When it has reason to fear danger from diseases which are generally recognized as communicable and dangerous to the public health, a court may be justified in taking judicial notice that the disease is within the statute, which in plain terms includes all diseases where there is danger to the public health from a threatened spread of the disease. Within reasonable bounds, at least, it says, the health officer's conclusion that a disease is communicable, and is a menace to public health, must be conclusive; otherwise the efficiency of health officers and boards would be seriously lessened, for persons would be likely to hesitate about furnishing necessary medicines and other commodities and rendering services if it involved the danger of review by another board, with power to disallow claims on the ground that the disease was not within the statute, or the goods furnished were not necessary. And the court is of the opinion that the allowance by the township board of health, which is identical with the township board in townships, was designed to be final, and where the law imposes the liability on counties it was intended that the allowance by the township board should bind the board of supervisors as to the character of the disease, the necessity, and the fitness of the articles and services furnished and rendered, as well as the fact that they were furnished. The question of the ability of the patient to pay is also foreclosed by the allowance by the township board. While the board did not keep, in a book of its own, an account of items furnished each person, the court holds that it was a sufficient compliance with the statute that they had before them and allowed such itemized accounts, and rendered such an account in this case. The requirement to keep and render an account was met when the board was able to render the itemized and separate statement required by statute. There was a bill for $149.50 for attendance on patients and consultation with other physicians allowed to the health officer of the township. While no direction to perform these services was given by the board, the court deems it enough that they knew that they were being rendered, appeared to have acquiesced, and afterward allowed the bill.

## AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

### Medical Record, New York.

*January 2.*

1 *A Plea for Justice to the Consumptive. S. A. Knopf.
2 *The Diagnostic Significance of Certain Reflexes and Tendon Phenomena. H. Oppenheim.
3 *Commentaries on Lues and Leprosy as Subcatabolic Diseases. Homer Wakefield.
4 *Diagnosis of Acute Lobar Pneumonia. Stephen Smith Burt.

1. **Tuberculosis.**—Knopf's paper is a plea for the tuberculous patient as against the too prevalent phthisiophobia of the day. He severely criticises the action of the New York Legislature in enacting the Goodsell-Bedell law against the establishment of sanatoriums for this class of cases, and the decision of the Marine Hospital Bureau making tuberculosis a dangerous contagious disease. He also gives especial attention to one or two recent papers which have charged victims of tuberculosis with possessing criminal tendencies, and brings forward evidence from high authorities against any such statement. The paper concludes with the resolutions proposed in the Society of Medical Jurisprudence against the above-mentioned enactment.

2. **The Diagnostic Reflexes.**—Oppenheim first notices the almost universal occurrence of the knee phenomenon and its importance. It is only in especial cases and mainly in degenerates that it may be absent, though there may be mechanical conditions preventing its recognition, such as a great development of fat, shortness of patellar tendon, etc. The heel phenomenon is now recognized as a constant reflex in health, but exceptions occur to a somewhat greater degree than with the knee phenomenon. Sciatica, for instance, may prevent it, especially sciatic neuritis, and the mechanical conditions above noticed. Alcoholism, diabetes, and other affections, may cause its disappearance, so that it is not of invariable significance as a symptom of spinal disease. As to the skin reflexes, he notices particularly the occurrence of the Babinski reflex in certain spinal disorders, but recognizes also that it is not of invariable occurrence. It is occasionally found in atonic conditions of the musculature, as well as the hypotonic. Coincident lesions of certain cerebral tracts or areas may prevent its occurrence, nor can we assume that its appearance indicates an anatomic change in the pyramidal tracts, as it may be occasionally demonstrated after epileptic attacks. Peripheral

disease or poliomyelitis with paralysis of the toes may also prevent its appearance In conclusion, he calls attention to a phenomenon which in significance is very close to the Babinski phenomenon and which he himself first observed and described In a normal individual, on stroking the inner surface of the leg from above downward, with either the thumb or the handle of a percussion hammer, or pinching a fold of skin on the inner surface of the leg, either no reflex movement will follow or a flexion of the toes will result Under pathologic conditions, that is, in pyramidal involvement, instead of the plantar flexion of the toes, dorsal flexion is observed This reflex differs from the Babinski not alone in the source of its inception, but in the fact that not only the extensor hallucis longus participates in the reflex movement, but also the tibialis anticus and often the extensor digitorum communis and the peronei The contraction of the extensors for the foot is physiologic when examining the plantar reflex, and the pathologic reflex is only known through the contraction of the extensors for the toes, whereas in Oppenheim's reflex the pathologic reflex is more plainly indicated by the involvement of other muscles In a few cases where the estimation of the toe reflex is uncertain, the Oppenheim reflex may be decisive.

3 **Subcatabolic Diseases.**—Wakefield includes syphilis and leprosy as coming under his class of subcatabolic conditions described in an earlier paper abstracted in THE JOURNAL, Dec 13, 1902, ¶13, p 1549 He brings forward lengthy arguments in favor of his views, asserting that the rational basis of treatment in every case must be the restoration of normal catabolism and the elimination of accumulated and decaying refuse of past subcatabolism and not an attempt at independent parasitic destruction

4 **Pneumonia.**—Certain difficulties in the diagnosis of aberrant pneumonia are noticed by Burt, and he remarks that only a frequent examination and chest exploration of all patients where there is a possibility of idiopathic, intermittent or terminal pneumonia will reveal the true condition The ordinary typical signs of pneumonia may be absent He points out more particularly the difference between pneumonia and typhoid and pleurisy Of course, beside the agglutination test, bacteriologic examination offers valuable aid, and bacteriologic examination of the blood may yet be of extreme diagnostic value where the pulmonary signs are indefinite and there is no expectoration

## New York Medical Journal

*January 2*

5 *Gallstones, Their Surgical Treatment B Farquhar Curtis
6 *The Surgical Treatment of Malignant and Non malignant Diseases of the Stomach Albert Vanderveer
7 *Hysterectomy for Infectious Disease of the Uterus and Uterine Appendages H C Deaver
8 *The Treatment of the Cardiac Toxemia of Pneumonia Henry L Elsner
9 *Some Investigations of a Bacterial Treatment of Tuberculosis (To be continued ) Stephen J Maher
10 *The Surgery of the Day Charles L Kelsey
11 *The Ocular Complications of Mumps J H Woodward

5 **Gallstones**—Curtis sums up the advantages of operation before grave infection has taken place in (1) The avoidance of such accidents and the improvement of existing inflammatory conditions, (2) the removal of the stone before it enters the common duct, with the dangerous consequences likely to follow, (3) the prevention of severe attacks of colic and cystitis, (4) stoppage of calculus formation, (5) the fact that latent cases are by no means free from danger, so that recovery from one attack of colic is no evidence that another one will not occur or that other stones may not remain behind or chronic cholecystitis persist, (6) it seems to be the general experience that in the latent cases while the patient does not have symptoms pointing directly to the bile passages, they are afflicted with various dyspeptic complaints which can be entirely and completely removed by operation

6 **Stomach Surgery**—Vanderveer describes the methods of operation in stomach surgery, more especially gastro enterostomy, and gives his own conclusions based on a variety and number of operations as follows

> 1 Gastroenterostomy can be applied to all kinds and conditions of stenosis of the pyloric end of the stomach
>
> 2 It is a preferable operation to that of resection of the stomach, in many cases, the immediate mortality being less and the possibility of the extension of life being quite as great, with as much comfort
>
> 3 Next to gastroenterostomy I believe gastrectomy to be the most reasonable and satisfactory operation, yet this operation will necessarily be limited to but few cases In doing it great attention should be paid to removal of the lymphatic glands, as in this rests much of the permanent success of the operation and non return of the malignant growth

7 **Pelvic Infection**—Deaver notes the progress of postpartum uterine infection, and protests against the practice of aspiration through the vagina in cases of pelvic abscess, as the needle may enter the intestine A better procedure is to open freely the cul de sac by an incision through the posterior vaginal vault Where the collection is so placed that it can not be reached by such incisions he keeps the case under the closest observation with careful feeding and the avoidance of purgation If the collection is in the upper part of the broad ligament and it is doubtful whether it can be reached by incision above Poupart's ligament, he makes an incision in the median line, just above the upper margin of the mass and carefully inspects its relation to the abdominal wall and viscera, and then packs with gauze above and to each side and evacuates without danger of soiling the peritoneal cavity, mopping out with iodoform gauze, exercising care not to destroy any adhesions Where the infection has passed into the tube, forming a pyosalpinx or tubo-ovarian abscess, he always operates by the abdominal route, tying off the ovarian vessels as close to the pelvic wall as possible, and rapidly excising the tube and ovary with scissors, following the incision right into the horns of the uterus, and closing the resulting wound with continuous suture He drains with gauze placed along the line of suture. In still another class of cases where the infection appears as a phlebitis of the uterine sinuses and veins of the broad ligament, with multiple abscesses and acute peritonitis, pronounced constitutional symptoms, diarrhea, etc, the question of hysterectomy presents itself. In most of these cases total hysterectomy is to be preferred Early operation can save the patient in some of these highly virulent and rapidly fatal forms of septic peritonitis which are similar to the fulminating forms of appendicitis, and surgery must be performed In infection from gonorrhea and dermoid cysts and from interligamentary and ovarian cysts, he is in the habit of performing supravaginal hysterectomy He considers it in badly infectious cases with dense adhesions the ideal operation, since it thoroughly removes all the diseased condition The floor of the pelvis is left with a serous covering by neatly stitching the apposed serous surfaces together

8 **Pneumonia**—The prime factor in pneumonia is a toxemia with obstruction in the pulmonary circuit This leads to cardiac asthenia with a liability to marked changes in the right heart and far reaching degenerative changes in the muscle, with heart clots and vasomotor paralysis The treatment must be prompt, radical and sustaining Elsner protests against the indiscriminate use of nitroglycerin in these cases, as it aggravates the lowered arterial tension from paralysis of the vasomotors There are three remedies which promptly meet the indications These are strychnia, digitalis and suprarenal extract The first two should be used hypodermically The latter acts on the heart and the blood vessels favorably, and not on the vasomotor center, and may be used to assist strychnia He quotes from a former paper in regard to the use of diffusible stimulants in these cases Compound spirit of ether, aromatic spirit of ammonia, compound spirit of lavender and tincture of valerium are recommended, giving 15 drops of each every fifteen minutes, and also doses of caffein and spartein sulphate, ¼ grain of the latter and 4 to 6 grains of the former, every two, three or four hours In the faithful administration of ethereal stimulants he has great confidence, and some of his colleagues have had equally good results

9 **Tuberculosis**—Maher's article, of which only the first part appears in this issue, is of interest He describes his experiments with a special bacillus cultivated from the whey of the milk of a consumptive cow, and his employment of its

cultures in the treatment of cases of tuberculosis, apparently with decided advantage. Several cases are reported. The bacillus seemed to be very long lived, as cultures survived in stoppered bottles for four years or more. He suggests as a remedy for this disease pure cultures of this bacillus, which he calls his X bacillus, given by injection. It is a spore-producing, gelatin-liquefying germ, growing in the presence or absence of air, in acid or alkaline media, at room or blood temperature, and seems to be hostile to other bacterial forms. Rabbits were inoculated with pure cultures without harm, whether in the tissues or veins, or abraded areas. (The article is to be continued.)

10. **Surgery of the Day.**—Kelsey criticizes the postgraduate schools, not that they do not furnish good instruction, but as teaching to those incapable of understanding and with no restrictions as to their use of it. He hints that students who attend postgraduate schools should be required to present some evidence of qualification, and that the schools should be placed under legislative control.

11. **Ocular Complications of Mumps.**—Woodward reviews the findings of various authorities as regards the ocular sequelæ of mumps, and reports a rare case of optic neuritis following the disease.

### American Medicine, Philadelphia.

*January 2.*

12 *The Early Diagnosis of Arteriosclerosis. Alfred Stengel.
13 *A Bacteriologic Investigation of Commercial Vaccine Virus. William T. Howard, Jr., and William H. Weir.
14 *The Methylene-blue Eosin Stains. Walter Baumgarten.
15 *Some Remarks on the Etiology of Hyperplasia of the Pharyngeal Tonsil in the Light of Recent Investigations. Thomas J. Harris.
16 Percentage Solutions, with Reference to the Metritic System. Joseph W. England.
17 *Seasickness: Etiology and Prophylaxis. E. Kirkland Shelmerdine.
18 *The Morbid Anatomy and Histology of Pulmonary Tuberculosis in Relation to Its General Pathology and Clinical Manifestations. G. Sims Woodhead.

12. **Arteriosclerosis.**—Stengel discusses the causes of arteriosclerosis, such as nervous strain, overwork, alcoholism, overfeeding, metal poisoning and infectious disease, especially syphilis. He thinks overfeeding as a cause has been neglected by physicians, as he has known a number of cases where no other factor was ascertainable. Heredity, of course, must not be lost sight of. The importance of early recognition is obvious, and he remarks as to the effects of loss of elasticity of the blood vessels on the heart. The four principal symptoms he mentions are the character of the first heart sound, its lengthening and heaviness; the accentuation of the second heart sound, a tendency to increase of what is called the "tidal" wave, and the determination of blood pressure. These, however, are not found in arteriosclerosis alone. He does not accept von Basch's opinion as to the importance of the persistent increase of blood pressure as a symptom of arteriosclerosis. Among the early clinical symptoms are change of vigor and of color and the various evidences of reduced vitality, an alteration of the skin, and of the activity of the sweat glands. Usually they are inactive, but there is sometimes a tendency to abnormal sweating. Increase in the total amount of urine is an early symptom, and variations in its specific gravity may also be noticed. The morning urine may be 1.025 and the evening urine 1.005 to 1.01. Later, occasional or continuous slight albuminuria appears. When the heart is especially affected there may be various phenomena of myocardial degeneration, arrhythmia, increased force of the apex impulse and suggestions of dyspnea. A tendency to ascribe irregularity of the heart in persons over forty to the overuse of tobacco, alcohol, coffee or tea is remarked on; more frequently it is the result of changes in the arterial system and the heart. Neither cause should be considered without the other. He finally calls attention to ophthalmic examination showing thickening of the retinal arteries.

13. **Vaccine Virus.**—Howard and Weir give the results of examinations of vaccine virus in Cleveland, showing the percentages of contamination. A rather notable point is that the virus obtained in the open market, as was that of Rosenau, showed much more contamination than that obtained from the dealers direct. The 9 varieties of actinomyces isolated will form the subject of a second paper. Few of them conform to the descriptions of previously recognized types, and none of them has caused suppuration or actinomycotic nodules in laboratory animals. This, however, the authors do not think is of importance, as such a result is rare in any case.

14. **The Methylene-Blue Eosin Stain.**—Baumgarten's paper is incapable of analysis in reasonable space. The first part is largely historical. The latter part contains the formulæ and methods of making a number of these stains. It will be an interesting paper of reference for the laboratory worker.

15. **The Pharyngeal Tonsil.**—The causes of enlargement of the pharyngeal tonsil are sometimes obscure. Heredity seems to play a limited rôle, and in a certain proportion of cases tuberculosis may be of importance, but syphilis seems to be of little account. The association of scrofula and struma is discussed at some length by Harris, and he notices the generally-conceded occasional factor of inflammation also at some length. He offers the results of his study in the following conclusions:

> 1. The pharyngeal tonsil possesses a distinct function or functions. 2. This function is of the nature of a defense against the entrance of bacteria and consists in a certain irrigation of the tonsil surface by a lymph stream loaded with lymphocytes. 3. This protection function carries with it the inherent qualities of the tonsil to enlarge on the slightest irritation for the affording of further power of defense. 4. This inherent tendency of the tonsil to enlarge is further seen in the frequent recurrence of the tonsil after removal. 5. Strictly speaking then, in the great majority of cases such enlargements are not a pathologic, but a physiologic process.

17. **Seasickness.**—Seasickness, according to Shelmerdine, is the result of three factors acting together or independently—mechanical, mental and the irritating action of the bile in the stomach. The mechanical action is from the constant change in position of the center of gravity, throwing unusual work on the antagonist muscles. Lack of loss of consciousness of involuntary effort has also an effect. The bile ducts are often overfilled, and the shaking up forces it into the intestinal tract, which is possibly suffering from constipation. The bile is often forced back into the stomach in enormous quantities. He summarizes that the pathology of seasickness is first in the presence of bile as a foreign body in the stomach: unnatural, spasmodic, muscular contractions, excessive spasmodic elevations of the chest and diaphragm, and compression of the contents of the abdomen—all causing a negative pressure in the stomach. Nervousness hinders the acquirement of proper balancing powers. He advises prophylaxis by a thorough cleaning out of the system before going on board ship, the use of laxatives, etc. In certain cases of very persistent vomiting, strapping of the chest, which thus restricts its expansion, will tend to quiet it. Calomel in large doses followed by a stiff saline is an excellent remedy, and the bromids may be used if these will stay down. In all cases the bile must be worked off. A seasick person should stay out in the fresh air and should not attempt to resist the motion of the vessel, but co-operate with it. Sea-legs and seasickness are incompatible.

18. **Tuberculosis.**—After some introductory remarks Woodhead takes up the subject of the curability of tuberculosis and refers to the observations of others that tubercular healed foci are frequently found in the lungs of elderly people dying of other diseases. His attention having been drawn to this fact, he took up the search for such evidence and found it in at least one in every three cases that came under his examination. He soon became convinced that even in cases that succumb to tuberculosis there is more or less marked evidence of sturdy resistance, and that failures to meet the attack were due to disadvantageous circumstances. While he holds that the tubercle bacillus is the origin of the disorder, he warns against the assumption that its contact with human tissues necessarily results in tuberculous disease. The tissues must be damaged or weakened and a special mode of entrance be prepared before the tubercle bacillus can do its mischief. For years his hands have been almost daily soiled with the tubercle bacillus, and he has no doubt he has swallowed many and some have made their way into his respiratory tract, but they have never done him any apparent harm because he has carefully

protected abrasions and cuts, and refrained from active pathological work when out of health. There must be some predisposing cause, a soil must be prepared. The routes of the bacillus to the lungs are by way of the air passages and by the lymphatic system. Woodhead points out the resistance of the tissues by throwing out of fibrous tissue, which is an evidence of good reaction. The third way of invasion of the organs by tubercle germs is by the blood. The bacilli are carried from the lesions of the lymphatics to the blood vessels, but all of the three routes are probably more or less coincident; these methods seldom occur alone. In case of phthisis, apical catarrh is generally the first condition noticed, accompanied by congestion and consolidation. If the patient is placed under favorable conditions of nutrition, rest and elimination, the reaction of the tissues is so complete that the dead patch is surrounded and cut off, and if not extensive may be completely cured. Under other conditions, however, it will spread. The small hemorrhages characteristic of the early stage of phthisis are explained by the altered conditions of the vascular circulation, the increased quantity of blood required to meet the want of the proliferating tissues, and they usually occur as the result of some extra temporary strain, and are an indication of the local changes. A patient that has once suffered from tuberculosis has no immunity to subsequent attacks, and we should insist on a continuation of the improved conditions which is advised for the first attack. These, however, Woodhead holds, can be provided by the patient himself in many cases. While sanatorium treatment is of great value in tiding over dangerous early periods of the disease, it is still more valuable in teaching the patient to carry out in his own home the same principles and methods. If he is sent to a special climate, he is apt to give the credit to the climate, and while this may be a factor, there is no fundamental difference between one climate and another as regards the curability of phthisis aside from the greater facilities afforded for open air and pure air treatment.

19 *The Management of Typhoid Fever Epidemics. George A. Soper.
20 *Anomalies and Difficulties of Diagnosis in Typhoid Fever. Henry L. Elsner.
21 *Management and Treatment of Typhoid Fever. Egbert Le Fevre.
22 Thoughts on Chlorine and an Antiseptic Technic. Douglas H. Stewart.
23 *Excision of the Frenum Preputti Following Laceration During a Suspicious Intercourse. Charles C. Miller.
24 *Chickenpox Concurrent with Smallpox. Philip D. Bourland.
25 *Morbid Anatomy and Histology of Pulmonary Tuberculosis in Relation to Its General Pathology and Clinical Manifestations. G. Sims Woodhead.

19. **Typhoid Fever Epidemics.**—The duties of the medical boards of health in case of typhoid fever epidemics are enumerated by Soper, who regrets the lack of scientific training in hygiene among physicians. He comments on the value of state oversight in even a local epidemic, as the authority of local boards does not go beyond their municipal boundaries. The number of cases should be thoroughly ascertained and special care taken to detect the mild, unusual and atypical cases, as from these is the greatest danger of spreading. The care of food supplies, use of disinfectants, proper safeguards against urinary infection, etc., are all noted.

20. **The Diagnosis of Typhoid.**—Elsner notices the anomalous cases of typhoid where the symptoms are difficult to determine, some stages of the disease being lacking, the prodromal period being unusually short, etc. The condition of the blood pressure is also noticed and its value, the absence of chills in many cases and of nose bleed, which used to be considered a cardinal symptom, and the possible complication of typhoid fever with other conditions. Malignant endocarditis is often confused with typhoid, as is also gonorrheal endocarditis. The peculiar characteristics of infantile typhoid, usually the shortness of the course due to the absence of extensive deposits in the submucous intestinal tissue, lesser involvement of the glands, etc. He believes that idiopathic remittent fever in children is almost universally enteric. Of course, the value of reaction tests and blood examination must not be overlooked.

21. **Treatment of Typhoid.**—Le Fevre principally emphasizes the importance of individualizing in the treatment of typhoid, and the too common dependence on routine methods.

23. **Excision of the Frenum.**—Miller advocates excision of the frenum in a case of its rupture, especially after suspicious intercourse. He would extirpate it with small curved scissors, and, as the result of extirpation, we have a groove about one-eighth of an inch deep and somewhat wider, which is sutured from up near the meatus back to the corona with continuous catgut sutures. Free oozing will commence, but the sutures quickly control it. The groove unites very rapidly, and if plain No. 1 catgut is used for suture material no further attention is required. It comes away in a few days, leaving the parts healed.

24. **Smallpox and Varicella.**—Bourland gives his experience with an epidemic of smallpox and the concurrence of chickenpox in Lake Linden, Mich., and emphasizes the following points:

1. The concurrence of smallpox in no way caused the course of my cases to depart from that typical of chickenpox.
2. Vaccinated and unvaccinated children showed equal susceptibility to infection, and the course of the sickness was the same in each class. This fact excludes varioloid.
3. None of my patients had ever been exposed to smallpox or had ever had it.
4. No adults were attacked notwithstanding absence of vaccination in a majority.
5. Five of the children exposed had had chickenpox in a previous epidemic, these previous attacks conferring immunity except in one instance.
6. Smallpox and chickenpox are distinct pathological entities, and though in intimate association, neither disease influences in any way the natural history of the other.

31 What Was the Cause of Death? A. Elliott Paine.
32 A New Frame for the Treatment of Fractures of the Lower Extremities. John H. Cunningham, Jr.

26. **Typhoid Fever in Children.**—Baginsky reviews the history of typhoid fever in children as it has been recognized in medicine, noticing that it was formerly considered to be a comparative rarity, but has of late years become known to be of greater frequency and of special interest. It is apparently more rare in infancy than in early childhood, but this is very likely an error of diagnosis, as typhoid in sucklings is often diagnosed as dyspepsia. Further and accurate observation will be required to settle this question. Boys seem to be more susceptible than girls, which Baginsky refers to their greater chances of infection. Typhoid in children is exceedingly easy to transmit, as they are naturally more careless about soiling surroundings. He comments on the probability of its being carried by flies as Vaughan has claimed, and which, he thinks, he has himself observed almost to a certainty. While the greater number of cases occur in the autumn, sporadic instances may appear at any time of the year. It is not yet certainly known how the bacillus affects the organism. It is questionable, he thinks, whether the typhotoxin of Brieger has anything to do with its effects. The various diagnostic reactions and pathology are discussed at some length as also the symptoms, which are often indefinite in children. The temperature is one of the most important aids in the diagnosis. In single cases the course of the fever both in duration and severity may be on a par with the worst cases in adults. The pulse corresponds pretty closely to temperature. During height of the fever it is irregular and intermittent. This irregularity is also observed in the convalescent stage, and the duration of the fever is apparently longer in older children. It seems to increase in duration in patients from one to ten years of age, according to Montmollin's studies. Other symptoms such as coated tongue, somnolence, diarrhea, epistaxis, cough, the agglutination

phenomenon, etc., are somewhat similar to those of adults. (The article is to be continued.)

27. **Biliary Colic.**—Cabot first refers to Fenger's suggestion that biliary colic occurs from obstruction in the biliary passages caused by a bending or kinking of the ducts. The author puts on record two cases which appear to have been caused by acute flexure of the gall bladder about its middle. Both were relieved by operation. In such cases from this experience he would prefer cholecystectomy as a cure for the condition. This was performed in the second case. In the first, fastening the fundus of the gall bladder to the abdominal wall effaced the bend in its body and stopped the attacks of hepatic colic, but it left a sensation of dragging in the hypochondrium which prevents considering the success perfect.

28. **Chronic Sphenoidal Sinusitis.**—Rogers describes his methods of diagnosing and treating chronic sphenoidal sinusitis. He uses a probe for diagnosis, passing it in a direct continuous line from the inferior nasal spine to the middle part of the middle turbinate, not allowing it to go anterior to this line. If the probe passes in a greater distance than 7.5 cm. it is either in the sphenoid, brain cavity or naso-pharynx. If it goes over the turbinate in the middle part, in the direct line mentioned, one is certainly in the sphenoidal cavity. In opening it he removes the anterior part of the middle turbinate and then fractures and removes the remainder, leaving a free and easy approach to the sphenoidal opening. He does not use adrenalin solution except in the after-treatment. In ten days he proceeds to open the sinus, which is done under cocain, with a forceps devised on the principle of Grünwald's down-cutting forceps, but with shorter jaws. His method has given complete relief in eleven cases, the notes of which are reported. A more extensive operation, such as that of Jansen and Luc by way of the antrum of Highmore, has not been necessary in a single case, since he has devised this method.

35 The Successful Treatment of Gonorrhea. A. H. King.
36 Surgery of the Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

33. **Foreign Body in the Bronchus.**—Oliver reports the case noted in the title and refers to several others in his experience. He thinks the following conclusions express the rational indications for and against tracheotomy in this class of cases:

1. Laryngotomy should always be resorted to when a foreign body lodged in the larynx can not be removed through the natural passages.
2. Tracheotomy may be required by reason of edema of the larynx even after the foreign body has been removed.
3. When the foreign body is impacted at or near the bifurcation of the trachea, a tracheotomy is to be viewed in the light of an aid to exploration.
4. The tracheotomy wound may be permitted to close, or even be closed by sutures, in case the foreign body has been removed.
5. Stitching the edges of the trachea to the integument is to be preferred to the tracheotomy tube in cases in which exploration has not been successful in removing the foreign body.
6. Tracheotomy is by no means always necessary in cases of foreign bodies located at or near the bifurcation of the trachea. Spontaneous expulsion will occur in many such cases unless the foreign body is rough or jagged. Attempts to remove such by instrumental aid through an opening in the trachea are urgently indicated.

45 Ovarian Cystomata, with Report of an Unusually Large Multilocular Ovarian Cyst. Charles R. Robins.
46 Pseudo-vaginismus. G. Kolischer.

41. **Catarrhal Enteritis in Women.**—Gillmore describes a class of cases in which the principal symptoms are anemia and neurasthenia with a subjective impression of disorder in the pelvic organs due to constant pain and soreness in the abdomen, bearing-down pain, backache, etc. The real condition in these cases, however, is catarrhal enteritis, which is relieved by proper treatment. He thinks that it is usually due to dietetic errors. Its pathology is rather obscure, as it is rarely fatal. The diagnosis is usually assured by ocular examination of the stools. The treatment consists: 1, in a selected but generous diet, regulation of the bowels by some form of cascara, and if there is a tendency to obstinate constipation or too free movements, using high colon flushing with mildly alkaline water or normal saline, followed by a quart of water containing 8 c.c. of normal fluid extract of hydrastis. He has had good results with a pill consisting of powdered ipecac, creosote, black pepper, naphthol, and hydrastis. Acetozone suggests itself, but as yet he has not employed it to any extent. In conclusion he insists on the importance of examining the stools in obscure cases which come to the gynecologist for relief.

42.—See abstract in The Journal, Oct. 17, 1903, p. 980.

44. **Pregnancy and Crime.**—Cumston discusses the effects of pregnancy on the mental and moral condition of females. He thinks the judgment and will power may be partially affected, but the sensory or moral disease is limited and only attacks isolated points. He concludes that where guilt is evident pregnancy can hardly be an excuse, but is quite permissible to invoke pregnancy as an attenuating factor in certain cases.

55 Anomalies in the Circle of Willis. With the Report of a Case in which the Communicating Arteries were Absent. Walter C. Howe.

47. **Kidney Suture.**—Goelet's article gives his methods of treatment which have been more or less detailed elsewhere. He says the essential differences between the Brodel suture used by Cullen of Baltimore and published in *American Medicine*, Aug. 2, 1902 (see The Journal, xxxix, Aug. 16, 1902, p. 396), and his own are: 1. That the apex of the triangle formed by the Brodel suture is above, the ends emerging on the surface of the kidney near together. In the Goelet suture the apex of the triangle is below, the ends of the suture emerging on the surface farther apart from each other and brought out and tied on the external surface. 2. The sutures are placed at a greater distance apart, the lower suture at the lower pole, and they include less area of surface. The Goelet suture does not include the lower pole, which is left normally free, and it includes a larger area of surface. Goelet uses silkworm gut and instead of burying the suture in the muscle he brings it to the surface and ties over a pad of gauze.

48. **Gauze-Bearing Tape and Gravity Pad.**—The gauze-bearing tape as used by Fisher is a piece of white tape about an inch and a half in width and of variable length (three or four feet), armed at one end with a long, blunt-pointed needle or bodkin. On this tape the gauze sponges in a laparotomy may

be strung. It has the advantage of doing away with the numerous separate gauze sponges used in abdominal operations. The gravity pad is a large gauze pad having concealed within its folds and near its center, a plate of lead, two by three inches, weighing about half a pound. Instead of a single piece smaller pieces may be quilted in at different points. The pad is provided with a trailer, though this is not essential as only one, and rarely two are required in a single operation. By these appliances he escapes the danger of losing and leaving sponges in the abdominal cavity. They also assist in the Trendelenburg and other positions in holding back the intestines, as weight properly distributed is more useful than bulk for this purpose.

50. **Gastric Surgery.**—Murphy discusses the various operative measures in gastric surgery and sees much encouragement in the results. He reviews the experience and technic of different operators and tabulates their results at different times since the operations were first performed. He emphasizes the importance of the prophylaxis of gastric carcinoma by early attention and operation in case of gastric ulcer, etc.

53. **Local Anesthesia.**—Connell's article is a general review of the subject of local anesthesia by various methods. He points out its advantages as follows: 1. The removal of the danger of death on the table; 2, the avoidance of after-effects of general anesthesia on the heart, liver, kidneys and lungs. Postoperative pneumonia seems to be about as frequent after one kind of anesthesia as the other; the absence of postoperative nausea, vomiting, or unconsciousness or danger of strangulation by fecal vomit. The patient being conscious, he is able to assist the operator. The number of assistants is reduced by one, though it may be convenient to have others at hand to meet the emergencies. There are many cases where local anesthesia is markedly contraindicated, but he holds that it should be used as an adjuvant to, if not a supplanter of, general anesthesia in many cases where the latter is commonly employed.

54. **Shock.**—According to Kinnaman's experiments and studies shock must not be considered as due to a lowering or exhaustion of one bodily function, but the composite result of interference with the blood pressure and respiration, lowering it in both cases, and a marked fall in the body temperature. As it increases in severity the fall in temperature is the most uniform and progressive symptom. The relationship between the lowered body temperature and shock is evidenced by considering: 1. That in one of the series of cases he reports the fall in temperature was the sole cause of the shock; 2, that where by continuous bath the temperature fell only 1 C., the respirations were increased instead of diminished, and the fall in the blood pressure was lessened. 3. That by raising the body temperature previously lowered in shock, the respiratory rate was increased and the blood pressure raised. The relationship he expresses thus: (*a*) A sufficient fall in body temperature can cause a decrease in the respiratory rate and a marked fall in blood pressure which, together with itself, we designate as shock. (*b*) Conversely, a limiting of the fall limits the fall in pressure and prevents a fall in the respiratory rate, thus limiting or preventing shock. (*c*) Antagonistically, a rise of temperature causes a rise of blood pressure and the respiratory rate (reduced in shock), thus ameliorating all the symptoms. Thus of the three factors temperature takes the first place by its power of production, its power of limitation and power of amelioration of the composite condition—shock.

### American Gynecology, Baltimore.

*November.*

56 *What Is Conservatism in Pelvic Infection? John O. Polak.
57 The Management of Occipito-posterior Positions of the Vertex. James D. Voorhees.
58 A Case of Inversio Uteri Puerperalis Reduced by a Modified Kuestner's Method. Max W. Myer.
59 *Pathology and Treatment of Gonorrhea in Women. A. P. Stoner.

56. **Conservation in Pelvic Infection.**—Polak believes in early intervention in pelvic infection; there is a time, could we but recognize it, when intervention will prevent further invasion. From his experience with 79 cases, several of which he reports, he thinks that the best chance of saving life and minimizing the sequelæ is obtained by proper surgery, and he has found Pryor's iodin treatment of great value in these cases. Of the 70 patients operated on, 58 have been kept under observation from six months to three years, and 5 reoperated on; 52 have had no further surgical treatment, and 39 of this number are practically recovered, having no pain or gross lesion requiring any attention. None have had subsequent pelvic peritonitis. Six complained of severe dysmenorrhea, but are free from pain between periods. Four in which the lesions were of gonococcal origin, while having no pain, complain of menorrhagia and have large, thickened and more or less fixed uteri, while 3 women have appreciable thickening in one tube. Of the 9 gonorrheal cases refusing operation during the acute attack, all have come under observation in one or more attacks of pelvic peritonitis, and 2 have well-defined pus tubes.

59. **Gonorrhea in Women.**—Stoner holds that gonorrhea, while a persistent and invading infection, is in the majority of cases overcome by the antitoxic elements of the cells, and may be called a self-limited disease. During the early stages cleanliness and rest are best. The trouble is generally over-treated. If the patient can be placed in bed and given a liquid diet and the infected parts kept thoroughly cleansed by sterile water, the results will be better than those obtained by some of the more active measures often employed. This use of sterile water does not imply the vaginal douche, which he thinks in many cases helps to spread the infection. During the first few days no further treatment is necessary except rendering the urine neutral and less irritating. After the second week a 2 to 4 per cent. solution of protargol or 15 per cent. of argyrol may be instilled into the urethra and also used in the uterine cavity. Curettage of the uterus is not advisable in the acute stages when the tubes and ovaries are infected. In the second stage methylene blue or urotropin may be used, and a plain diet prescribed, consisting largely of milk. The patient should rest absolutely, or at least avoid hard manual labor during the first week or ten days. Should the infection extend to the uterus the tubes are almost sure to be involved. If salpingitis develops, rest in bed becomes imperative. Frequent hot douches, ice bags or turpentine stupes should be utilized to control the pain. Much must be left to Nature but she is frequently unable to cope successfully with the infection until the peritoneum is reached and an exudate thrown out which, for the time being, prevents further inroads. Then the intervention of the surgeon and removal of the diseased organ is called for.

60 *Regarding Croupous Pneumonia, Especially Its Treatment with Carbonate of Creosote. J. A. Scott and Charles M. Montgomery.
61 *Thirty Years' Experience with Crude Petroleum as a Therapeutic Agent. A. D. Binkerd.
62 *The Question of Priority as to Childbed Fever—Holmes vs. Semmelweis. Simon Baruch.
63 Headache as a Symptom and Its Treatment. Ellice M. Alger.
64 The Oil-massage Treatment of Abdominal Tuberculosis. Duncan Turner.

60. **Pneumonia.**—Scott and Montgomery have experimented with the use of creasote in the treatment of this disease, and find that it causes no stomach irritation and that the degree of toxemia, in all cases, barring the fatal ones, was mild. That in the cases treated, pseudocrises were common but had no relation to the crisis or mortality. That the mortality percentage (14.9) secured in 67 cases treated with carbonate of creosote does not corroborate the unusually low figures of Wilcox, Van Zandt and others, nor does it prove that the results are due to the treatment by creosote carbonate, as equally good results have been secured in past years by other methods. The study of the clinical effects of carbonate of creosote should be continued, the dosage increased and the effect on the toxemia carefully watched. Brief reports are given of the fatal cases.

61. **Crude Petroleum.**—Binkerd has used the finest grade of crude petroleum and with the best results in all forms of acute affections of the respiratory tract in his practice at West Monterey, Pa. It relieves the labored and stridulous breathing, cyanosis disappears and expectoration is facilitated, the fever subsides and the patient goes on to convalescence and prompt recovery. He experimented on himself when in bad health from malassimilation, hemorrhoids and rectal prolapse, using crude

or entirely suspended. Examination of the livers of 3 diabetic subjects has confirmed this assumption. Not a trace of glycolysis could be detected in the liver in 2 of the cadavers, and only minimal traces in the other, and this was precisely that of a subject with mild diabetes, who had succumbed to intercurrent pneumonia. Jacoby has also mentioned the entire absence of evidences of glycolysis in the liver from a severe case of diabetes. This material is too limited for general deductions, but in future the liver of diabetics should be tested for glycolysis, both alone and with addition of pancreas. From the therapeutic point of view, these new facts suggest the advisability of organ therapy with the glycolytic ferment, plus pancreas extract. This has been impossible hitherto on account of the difficulty of isolating the glycolytic ferment in a soluble form. When this is accomplished, then we can hope to benefit mild and medium cases of diabetes by injection of the ferment, plus the specific substance from the pancreas. This will promote the sugar destruction in the tissues, especially in the muscles, to an extent sufficient to allow the ingested carbohydrates to be utilized for heat and energy production without calling on the albumin of the body. Even in severe cases some benefit will undoubtedly be derived if these premises are correct. This treatment with the glycolytic ferment will probably not affect the other disturbances in metabolism entailed by the loss of pancreas functioning. It is possible, however, that the pancreas may contain other substances able to influence these other disturbances. This hypothesis is suggested by Jacoby's experience in a certain case in which after administration of 5 gm. pancreas tablets a day the elimination of ammonia which had previously been 2.8 to 3.5 gm. dropped to 1.5 gm. No influence on the elimination of sugar could be detected. In conclusion, Blumenthal comments on the promising outlook for further research on the active substances in the pancreas and their utilization in therapeutics.

65. **Morphin-Scopolamin Narcosis.**—Volkmann describes his experiences with this method of narcosis which he qualifies as a great advance.

68. **Polyvalent Antistreptococcus Serum.**—Tavel gives the details of a few cases out of his experience in which the abdomen had been contaminated with streptococcus pus from some process and the laparotomy wound had been infected. The possibility of such an infection had not been thought of at first, as the excised organs were found sterile. Prophylactic injection of the polyvalent serum was followed by smooth recovery. In other cases the symptoms recurred after suspension of the serum treatment and vanished again on its resumption. As a particularly demonstrative case he cites that of a young man with nephritis and pure cultures of streptococci in the urine. After three weeks of gradual improvement the patient was burned out and caught cold, followed by pleuritis, bronchopneumonia and peritonitis, with symptoms of severe general sepsis. As the salicylates, baths and quinin had no effect, 10 c.c. of the serum were injected, and the next day the patient felt as if new born. The symptoms returned later and a second injection was made the fourth day, after which the temperature dropped as in a crisis, and the patient rapidly recovered. The temperature fell immediately after the first injection from 40 C. to normal, but then gradually rose again, subsiding at once and permanently to normal after the second injection. His clinical and experimental experiences have amply convinced Tavel that the polyvalent antistreptococcus serum, prepared without previous passage through animals, may be actually regarded as a specific against streptococcus infection. The lack of adequate dosage, the difficulty of producing a serum to fit all cases, and the circumstance that the serum, as a specific serum, contains only the amboceptors which stimulate phagocytosis or fasten the complements to the bacteria, while it does not contain the complements themselves which are sometimes lacking in advanced stages of infection—these are the reasons why it is not invariably successful. He adds that if we can succeed in stimulating phagocytosis and in the severer cases supply the missing complements along with the specific serum, then we can count on successfully combating the disease process even in the severest infections. (Tavel's serum was described more fully in The Journal, xxxix, page 731, 1902.)

75 Aetiologische Studien über die Epityphlitis. D. v. Hansemann.
76 *Bakteriämie und Sepsis. J. Möller (Altona).

71. **The Red Marrow in Acute Infections.**—Fraenkel has continued his bacteriologic and histologic studies of the red marrow of spine and ribs in acute infectious diseases. After the subsidence of the acute local process the bacteria are liable to persist in the marrow. The pathologic changes in the marrow are the expression of the defensive reaction to the intruding and proliferating bacteria—giant cells, lymphomata, extravasations and cell necrosis. In 18 cases of disease due to the *Diplococcus lanceolatus*—including 13 of pneumonia—the germ was found constantly in the marrow of the vertebræ, more rarely in the ribs. The number of bacteria in the marrow paralleled that in the blood, contrary to what is observed in typhoid fever. The presence of the bacteria in the blood does not seem to affect the prognosis of pneumonia. Death seems to be due more to the action of toxins. In 17 cases of affections due to the streptococcus these germs were found constantly in the marrow. In one of the 7 cases of erysipelas in this group the blood swarmed with the streptococcus and *Staphylococcus aureus*. In 10 cases of scarlet fever streptococci were found in the marrow in every case with the exception of one in which the patient succumbed the second day. In staphylococcus affections (phlegmons, acute spontaneous osteomyelitis), the cocci were found constantly in the marrow. In 13 cases of diphtheria of the throat the marrow was found to be sterile in 3, and diphtheria bacilli were found in it in only one instance; in the others streptococci were constant. In 3 cases of pulmonary phthisis cocci were found constantly in the marrow, but never the tubercle bacillus. In 6 cases of peritonitis the causal agent was found in the marrow in all but one. Four cases of various other affections were investigated. In one of them—a fatal, intermittently febrile mastitis—no cultures could be derived from the marrow. Fraenkel was unable to discover any laws governing the penetration of bacteria into the marrow or the time required. He defends his research against the possible aspersion that his findings might be postmortal phenomena.

74. **Tendon Transplantation in Infantile Cerebral Paralysis.**—A child nearly 10 years old exhibited a severe spastic paraplegia, especially marked in the legs, with choreic and athetotic symptoms, consecutive to encephalitis three years before. He was treated by tendon transplantation. The tendons of the biceps, semitendinosus and semimembranosus were detached and transplanted in the upper edge of the patella, with extension of hip and knee joints. The same operation was then done on the other leg. The results were excellent. The spasmodic movements were improved at the hip joint and completely banished at the knee, while they persisted unmodified at the ankle and toe joints which had not been operated on. The child was able to flex and stretch the knee, previously impossible. Wittek ascribes the improvement to the interposition of new centripetal stimuli by the transplanting of the tendons.

76. **Bacteriemia and Sepsis.**—Möller was able to save 3 out of 13 cases of sepsis in which the blood contained bacteria. One patient was treated with daily injection of 40 c.c. of Marmorek's serum, in addition to the usual saline infusion and extensive surgical intervention. He reports an epidemic of 149 cases of scarlet fever with mortality of 45 per cent. He found streptococci in the heart blood in 11 out of 17 scarlet fever

cadavers, but not until after the third day. Thirteen of the patients were treated with Aronson's serum—all severe cases—with 3 recoveries.

78. **Mental Disturbances in Tabes.**—Schultze describes 2 cases of tabes associated with typical senile melancholia in one, and in the second with dementia precox paranoides. The tabes preceded the psychosis in the first case, but in the second the psychosis had existed four and a half years before the tabes and persisted unmodified by the latter. He regards the psychosis in each case as a casual accompaniment of the tabes and liable to have occurred without the latter. As a rule, when mental disturbances are observed with tabes they are usually of the nature of paralysis. The presence of the tabes alone should not impose the diagnosis of paralysis. Both his patients were syphilitics, and he quotes parenthetically a certain neurologist, who stated that he knew of but a single exception to the law of the connection between syphilis and tabes.

79. **Vessel Crises in Tabes.**—Pal comments on a fact which has hitherto escaped attention, namely, that the gastric crises in tabes are a vasomotor phenomenon. During the crisis of pain the nerve ganglia are extremely sensitive, and he argues that the true seat of the pains is not in the stomach, intestines or heart, but in the sympathetic plexuses. He cites Buch to the effect that in the nervous gastralgia of gastroptosis the pain is referred to the stomach, yet in reality the sensitive aching point can be located at the solar plexus. He further demonstrated that except for the site, the symptoms of angina pectoris coincide with those of nervous gastralgia and enteralgia. Pal has recently announced his discovery that contraction of the smaller vessels of the intestines is liable to induce intense pain. Riegel has recently also called attention to the connection between the pains and the tension of the vessels in lead colic. The intestinal walls have no sensory nerves, but Pal has established by experimental research that contraction of the peripheral vessels in the abdominal viscera interposes an enormous resistance to the blood wave in them. The arterial vessels in the mesentery are in consequence unable to empty themselves; the blood accumulates and they become distended, rigid and tortuous, pulsating violently and pressing on the surrounding tissue. These processes excite the sensory apparatus in the mesentery and especially the extremely sensitive solar plexus, which is further excited by the behavior of its own vessels. He has further established that the major gastric and abdominal crises in tabes are accompanied by a considerable increase in the tension of the vessels, in some instances fully 150 per cent. of the previous tension. He has discovered the still more significant fact that these processes in the vascular system which entail the exalted tension are primary and the cause of the pains in the crises. The attacks of pain do not commence suddenly; their development can be watched after the onset of the extraordinary tension in the vessels. The proof of these affirmations is afforded by the fact, which he has amply established, that it is possible to arrest the pain and the other symptoms of the crisis by reducing the tension of the vessels. It is immaterial whether the tension is combated by internal or external measures, or whether the reduction is accomplished by some intercurrent attack; all that is necessary is the lowering of the vascular tension. If the reduction is only transient the return of hypertension is accompanied by a renewal of the pains. Acute hypertension of the vessels is liable to induce symptoms which he groups as (1) headache and vertigo, (2) transient focal manifestations (amaurosis, asphasia, transient paralysis), and (3) loss of consciousness and convulsions. The first group usually accompanies the crises of tabes and the other groups are observed exceptionally in it, as likewise in lead colic, acute uremia, eclampsia and other processes which, although composed of dissimilar elements and proceeding from dissimilar sources, yet possess in common a hypertension of the vascular system. And it is to this hypertension that therapeutic intervention should be addressed. Treatment varies for each, as some of the conditions are essentially different in each.

80. **"Enriching" Method of Cultivating Typhoid and Paratyphoid Bacilli.**—By the technic described scanty bacilli were induced to multiply 350-fold, and enabled the correct diagnosis to be made in 8 out of 20 positive cases in which it would have been impossible by any other known means. These were the results of 180 single examinations of stools or urine, the other members of the family being always examined with the patient. The technic for the typhoid bacillus is stated to be the simplest and best yet offered, and ideal for the paratyphoid bacillus. The stool is mixed with twice the amount of salt solution, and .1 to .2 c.c. are distributed with a glass spatula over a malachite-green agar plate. The spatula is then transferred to a litmus-lactose agar plate as with the Drigalski-Conradi technic. After twenty hours in the incubator the blue plates are examined first. If no typhoid colonies agglutinating with typhoid serum are discovered on them, or on the green plate, about 2 c.c. of bouillon or salt solution are poured over the plate and a loop with four or five of the most suspicious looking colonies is transferred to two large litmus agar plates. They are then examined again for typhoid and paratyphoid bacilli after a sojourn of sixteen to twenty hours in the incubator. No other bacteria grow on 1/4,000 or 1/6,000 malachite green so vigorously as the paratyphoid bacilli. The agglutinability is somewhat reduced by this technic, but it is regained after transference to the blue plate. The malachite green inhibits or retards the growth of all other bacteria except the dewdrop colonies of alkali-forming bacilli, and these are readily differentiated.

81. **Limitations of Hypnosis in Therapeutics.**—Stegmann ranks hypnosis on a par with other tried and valuable therapeutic measures, although far from a panacea. Its limitations are sharply defined. He thinks that persons with normal psyche are the best subjects, as the effect produced is permanent, while it soon wears off with subjects of hysterical character or weak wills. Functional disturbances are the only ones that can be directly treated by it with success, and it is not the hypnosis but the suggestion which cures. The alterations in the psychic functions may in turn induce organic changes, and thus the hypnosis may indirectly benefit the latter. He has found it a particularly valuable aid for inducing sleep in exhaustion from insomnia, in nervous headache, in alcoholism, and especially in cases of disturbances in the innervation of the heart, respiratory and digestive organs and the urogenital system, although it can be successful only when,

as emphasized above, the disturbances are functional, not organic. Hypnotic sleep has a remarkable effect in sharpening the memory, and this property can be successfully utilized to ascertain the causes of puzzling disturbances. He describes a number of cases of delirium tremens cured by hypnosis, but points out that the subjects were men of normal character, temporarily obscured, but not perverted, while this treatment invariably failed in shallow, hysterically inclined subjects.

82. **"Occult" Blood in Diagnosis of Stomach and Intestinal Affections.**—Schmilinsky qualifies the "occult" blood test as the most important contribution of late years to the diagnosis and prognosis of certain gastro-intestinal affections. He states that the technic of spectrum analysis is much facilitated by transforming the hemoglobin into hemato-porphyrin, which is easily accomplished by adding a few drops of concentrated sulphuric acid to the diluted feces. If the fluid is in a vial with flat walls, the hemato-porphyrin can then be readily distinguished in the spectrum. He asserts that in applying the guaiac test the gradations of tint up to the blue are as characteristic as the blue itself. The scale of tints is first a deep green, then a peculiar changeable tint varying from green to a reddish-brown tint. This becomes more decided and blends into a violet in which first the red is more prominent, until finally the blue predominates. In case of mere traces of blood this scale of tints may not be entirely completed, but any step of the scale is as characteristic as the final blue. He advises that the patient should avoid all medicines, meat and vegetables containing chlorophyll for three days. On the third day the intestines should be evacuated with a very mild saline or with castor oil. He prefers the feces to the stomach content for this test, and seldom uses the latter except when a control is urgent. Beside ulcer and carcinoma, he thinks that the occult bleeding is liable to be encountered in cases of severe motor disturbances. The occult blood is peculiarly valuable for differentiating cases of gastric cancer in which no tumor can be palpated and the motor function is still good. Absence of the occult blood or its disappearance after lavage of the stomach and dieting, renders a malignant process improbable. This is especially valuable for the differential diagnosis between carcinoma and ulcus pylori. (Boas' recent communication on the subject was reviewed on page 1565 of the last volume of The Journal.)

86. **Action of Blood and Bile on Fermentation Processes.**—Hahn's article is practically a sequel to Jacobsohn's, just preceding. Hahn states that the insignificant results obtained in attempts to produce an antiserum with enzymes are due, he thinks, partially to the defective absorption, but chiefly to the binding and destruction of the injected ferments by the carbohydrates and albuminoids circulating in the blood.

88. **Blood Count in Acute Appendicitis.**—Rehn denies that the blood count is of value for the diagnosis or prognosis of acute appendicitis. Before there is much leucocytosis the patient's fate is usually decided. He tabulates 19 cases in which the blood count was followed by operation. In 2 there was hyperleucocytosis of 28,000 and 40,000, six and thirteen days after the onset of symptoms, and the diagnosis of appendicitis with abscess formation was confirmed by the immediate operation. In 5 the conditions were found to be identical, and yet the leucocytes numbered only 12,000 to 15,000, six to twenty days after onset. In 4 other cases with conditions identical, the leucocytes numbered only 8,000 to 10,000 four to twelve days after the onset, but an abscess was found as in all the other cases above. All the patients recovered after operation. In 6 cases of diffuse peritonitis only one showed leucocytosis of 19,000 and the others had only 11,000 to 14,000 one to nine days after the onset. The only case in this group that did not terminate fatally had a leucocytosis of 14,000. In 2 other cases of diffuse peritonitis, one patient with 8,000 leucocytes the first day after onset recovered, while the other, with 10,000 the fourth day, succumbed. Rehn advocates operating in every case of "fresh perityphlitic tumor."

89. **Post-Traumatic Nephritis.**—Oberndorfer reports a fatal case of acute fatty degeneration of the parenchyma of the kidney which was observed in a restaurant keeper 49 years old. Twenty years previously he had had a brief, transient renal hemorrhage and ten years later had lost a large amount of blood from the amputation of a finger. Otherwise healthy. The symptoms of nephritis developed after an insignificant trauma. In descending the stairs he overlooked the last step and stepped down heavily with his right foot on the floor of the hall. He experienced at once great pain in the leg and could not walk. It was still painful and stiff the next day, and the patient was very restless, with complete insomnia and pulse 120, regular, but small and weak, no appetite. He grew constantly weaker and symptoms of pronounced nephritis became evident the eighteenth day, with death in five days. The pelvic muscles were found lacerated, with considerable extravasation.

90. **Tuberculous Peritonitis.**—Thoenes summarizes the results of operative treatment of tuberculous peritonitis in his experience at Hamburg in the statement that 10 out of 21 cases were cured by the intervention. This is an average of 48 per cent. The 10 cases without adhesions were all cured but 2, but only 2 were cured in the 11 cases with adhesions. The Göttingen statistics are still more favorable, having 12 cured out of 19 with serous exudate and 3 out of 6 with adhesions. That is, 60 per cent. recoveries in all—15 out of 25 cases. The general average in the literature is 61.3 per cent. recoveries in the form with serous exudate, that is, 114 cases out of 186; 30.6 per cent. recoveries in the 55 cases with adhesions, and a general average of 54.1 per cent. recoveries—132 cases out of 244. He states, on the other hand, that the published statistics of internal treatment alone show only 38 recoveries in 82 cases, an average of 48.2 per cent.

91. **Successful Treatment of an Inoperable Sarcoma with Roentgen Rays.**—[This communication attracts attention—aside from its subject—as our confrère in Athens, Greece, seems to be so familiar with American contributions and quotes extensively and almost exclusively from The Journal and other American medical papers, although he gives due credit to the French and Germans. His therapeutic efforts were evidently based on the work of Americans.—Ed.] The patient was a woman of 35, and the tumor in the right hypogastrium was found at the laparotomy to be an inoperable, round-celled sarcoma. Cachexia was already marked. Five months after clinical healing under $x$-ray treatment, the patient returned for advice in regard to impending obesity, which fact emphasizes the completeness of the cure attained.

# Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. *A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.*

Organic and Physiologic Chemistry. A Manual for Students and Practitioners. By Alexius McGlannan, M.D., Associate Professor of Physiologic Chemistry, Instructor in Clinical Laboratory, College of P. and S., Baltimore. Series Edited by V. C. Pedersen, A.M., M.D., Instructor in Surgery and Anesthetist and Instructor in Anesthesia of the New York Polyclinic Medical School and Hospital. Illustrated with 9 Engravings. Cloth. Pp. 246. Price, $1.00. Philadelphia and New York: Lea Brothers & Co.

Treatment of Neurasthenia. By A. Proust, *Professor à la Faculté de Médecine de Paris*, and Gilbert Ballet, *Professor agrégé à la Faculté de Médecine de Paris Medecin de l'hopital Saint-Antoine*. Translated by Peter Campbell Smith, L.R.C.P., L.R.C.S., Edin., L.F.P.S., Glasg. Cloth. Pp. 213. Price, $2.00. New York: Edward R. Pelton. 1903.

The Practical Care of the Baby. By Theron Wendell Kilmer, M.D., Associate Professor of Diseases of Children in the New York School for Clinical Medicine. Cloth. 12mo. Pages, xiv-158, with 68 Illustrations. Price, $1.00 net, delivered. Philadelphia: F. A. Davis Company.

Anatomy Applied to Medicine and Surgery. By D. E. Mundell, B.A., M.D., Professor of Applied Anatomy, Faculty of Medicine, Queen's University, Cloth. Pp. 499. Price, $3.00. Kingston: Printed at the British Whig. 1903. New York: E. R. Pelton.

The Practitioner's Guide to the Diagnosis and Treatment of Diseases of Women. By Gustavus M. Blech, Professor of Operative Surgery, Jenner Medical College. Cloth. Pp. 112. Price, $1.00. Chicago: M. Robertson & Co. 1903.

The Transactions of the Society of Anesthetists. Volume VI. Cardboard. Pp. 86. London: John Bale, Sons and Danielsson, Ltd. 1903.

## Address.

### THE DOCTOR IN POLITICS.*

CHARLES A. L. REED, A.M., M.D.
Chairman of the Committee on Legislation of the American Medical Association.
CINCINNATI.

An invited speaker, when contemplating the demands of propriety with which he is about to be confronted, experiences the conflicting emotions of certainty and uncertainty. He is certain, for instance, as I am certain this evening, that he is the recipient of a conspicuous honor in being asked to engage the attention of his colleagues in a learned profession; and he is equally certain, as I am this evening, that he owes his acknowledgments of profound gratitude for the distinction that has thus been conferred on him. But unfortunately, at this point, and in the absence of an assigned topic, his feeling of equanimity deserts him, for if there is one thing more than another that he does not know, it is which subject, within the range of his limited capacities, will appeal with greatest interest and effectiveness to an audience that is familiar with all subjects. I have gone through the reflections enforced by this predicament, and in concluding to discuss the relations of doctors to the general life with which they are surrounded and of which they are a part—or, more specifically, the doctor in politics—I must offer an explanation which may at the same time serve as an apology. The explanation is to be found in the fact that I, like other objects in nature, when left to my own inclination, generally follow in the direction of least resistance, which declaration divested of its enigmatical features, means that by virtue of my accidental connection with the great work of organization in our profession, and by virtue of my present position as chairman of our National Committee on Medical Legislation, I have been brought face to face with this very theme. At the same time I feel that in discussing it here to-night I am simply carrying coals to Newcastle; for, if I were to say that I felt otherwise I would intimate that, here in Kansas City, there are neither doctors nor politics, which, I hasten to assure you, are two suspicions to which you have never been subjected.

#### "DOCTOR" AND "POLITICS."

Now, it will be assumed, naturally and correctly enough, that, on this occasion and in this presence, I use the word "doctor" in its popular significance as the synonym of one who, whether physician or surgeon, is qualified by education and law to practice the healing art. At the same time, I do not wish to lose sight of the fact, which I really wish to emphasize, that a doctor is not only one skilled in a profession, but should mean one who, in addition, is a learned man, and one who, moreover, has both the capacity and the inclination to teach others.

If, however, the word "doctor" demands definition here in the presence of doctors, how much more does the word "politics" need to be defined in the presence of men, every one of whom, as occasion offers, doubtless protests that he knows nothing about politics and that he takes no part in public affairs? First, then, let me say that I do not employ the word in its restrictive sense to imply activities calculated to influence and control the electorate by unworthy means to equally unworthy ends. The meaning that I attach to the word is, rather, the antithesis of this, and embraces a knowledge and practice of that science which, beginning with the intelligent exercise of the rights of citizenship, comprehends nothing less than the regulation of the nation, by lawful means, for the conservation of its safety, peace and prosperity. Within the purview of this science some such subordinate themes as the electoral franchise, the organization and management of parties, the natural laws of politics, abstract politics, the practical management of the affairs of state, political economy, police or municipal regulation, positive or constitutional law, the practical law of nations and even the science and art of diplomacy.

#### CIVIC RELATIONSHIPS OF THE DOCTOR.

What, then, you will inquire, in the light of these definitions, are we to recognize as the relationship, natural or otherwise, between doctors and politics? That the two are related, in a more or less fundamental way, becomes at least vaguely apparent when we reflect on the general unity of things; when we realize that nothing exists that is not related to something else, and this, in turn, to still something else, and so on until all things—arts, science, life itself—are bound together in an indissoluble whole. The constitution of the social fabric, of which the doctor is an integral element, furnishes a special application of this generalization. But it is not necessary to go into a critical analysis of the cosmos to discern the more intimate character of this relationship. We may get at the subject rather more directly by observing, first, that the relationships of the doctor, in point of knowledge, are as the relationships of his science. Thus, for example, his knowledge of human structure and of human function gives him a certain conception of structure and function, and the correlation of the two, as manifested in every phase of organic life; while his study of vital phenomena as modified by conditions, his accumulation, comparison and classification of facts, enable him to arrive at a conception of fundamental law, of natural law, of which all constitutional or statutory laws are but attempted adaptations. We make another approach to the subject if, in the next place, we consider that the special relations of the doctor are as the special relations of his profession. These relatyphoid at Plymouth, Pa., Ithaca, N. Y., and the last, at this very time, at Butler, Pa., each one of which was entirely and easily preventable under adequate laws and efficient executive administration. The necessity for inspection, by constant patrol, of all sources of general water supply; in fact, the protection of all the sources of life from the contaminations now being perpetrated, are subjects that the medical profession must bring home to the popular intelligence and the popular conscience.

---

* An address delivered before the Kansas City Academy of Medicine.

### SOME PRESSING RESPONSIBILITIES.

Then there are some responsibilities that we must recognize as being constantly before us. Thus, the status of the medical service in both the Army and the Navy and under the Bureau of Public Health and Marine-Hospital Service, must always be the object of interested concern to physicians in civil life, if for no other reason than that the demonstrated efficiency or inefficiency of such service is accepted, in a degree, by the public as a criterion of the efficiency or inefficiency of the medical profession in general. This was lamentably demonstrated during the Spanish-American war when the flower of American manhood, assembled in a salubrious climate, fell victims to preventable disease and died in such numbers that the record must forever remain one of the blackest pages in our military history. This calamity, calamity if not crime, resulting as it did from the arbitrary course of the commanding officer, Gen. John R. Brooke, in disregard and offensive disregard of the advice of his sanitary officers, was at once charged by the public to the inefficiency of the medical corps. "Where is your boasted sanitary science?" "Where is your progress in the art of curing?" were the questions impertinently asked of doctors all over the country. Happily, the contrasting picture was furnished by a representative of our own profession, Dr. Leonard Wood, who, as commanding officer in the field, at the head of troops in the insalubrious climate of Cuba, made a record for the healthfulness of his command that must remain an object of pride and emulation; and who, subsequently, as military governor successively of the pestilential cities of Santiago and Havana, redeemed them to health, to commerce and to civilization—a conspicuous service for which, if for no other reason, he deserves the gratitude not only of our own profession, but of the Congress and the country. The efficient service of Surgeon-General Wyman, who, at the head of the Public Health and Marine-Hospital Service and in connection with state health authorities, prevented the invasion of the country by the bubonic plague, is another instance that has helped the medical profession to retrieve the prestige it unjustly lost in consequence of the Brooke blunder at Chickamauga. These examples are enough, however, to show why, from selfish, if for no other reasons, the medical profession must always regard the interests of its representatives in the public services as its own interests; why their business must, to an important extent, always be regarded as its business. I hasten, however, to state that the medical profession, while not relinquishing the right of initiative, will not manifest this interest by obtrusive meddling in the administrative details or in matters of policy, but that so far as is now apparent, it ought chiefly to promote such suggestions and requests for congressional action as may emanate from the heads of the respective services.

There are, however, in addition to the foregoing demands for the consideration of the medical profession, a number of others pertaining to the other departments of government. Thus, for example, the Department of Agriculture has, at different times, brought forth recommendations relative to measures of deep concern to the public health. Some of these recommendations, notably those relating to the animal industry and those concerning entomologic problems, to say nothing of those calculated to protect our food supply, are of decided interest to physicians and have already been crystallized into laws. A pending recommendation relative to a complete survey and classification of the medicinal flora of the United States and insular dependencies, with determination of the alkaloidal constituents and constitutional effects of each plant—is one that appeals to the physician, not only because it may enrich his remedial resources and thus benefit humanity, but because, in its economic and commercial aspects, it is fraught with great possibilities. Another recommendation that has emanated from the Department of Agriculture is one providing, by means of analysis, assays, inspections and certification for the purity of all pharmaceutical and proprietary medicines, exposed for sale in the United States, and for a laboratory in which to carry on the work. That there is a necessity, and a pressing necessity, for such a bureau is apparent to every physician who is familiar with the unsatisfactory if not deplorable state of sophistication in medical supplies; that the regulation of this condition is a proper function of government, and that it can not be done by any other than governmental agencies seems to be indicated by the uniformly disastrous experience of the medical profession in attempting to control other irregularities by voluntary means; from which follows the conclusion that our duty as a profession lies in the direction of securing legislation by the Congress, whereby our medicines, like our foods, shall be subject to inspection and certification by the National Government.

### UNIFORM MEDICAL LAWS.

Another object, already hinted at, to which the organized profession should devote its serious attention, consists in securing the adoption, by all states, of uniform laws relating to the public health, to vital statistics and to the regulation of the practice of medicine. It seems that, under the organization of our national and state governments, respectively, police powers, of which sanitary and medical laws are but expressions, were reserved to the states and that, consequently, such laws can not be enacted by the National Government, except insofar as they may relate to commerce between states. This being true, it follows that no national law can be enacted that will touch these subjects—a condition that has resulted in the lack of uniformity in state laws and the consequent inability to secure co-operation between the states in their enforcement. In the face of this state of affairs it seems to be the duty of our profession, as now organized, to secure, through its constituted committees, drafts that will serve as models for the three sets of laws indicated; and that, as occasion arises for the amendment of existing laws or for the enactment of new ones, it is our duty to press these models for adoption by the various states until, in effect, the laws on public health, vital statistics and the practice of medicine, shall be uniform all over the United States.

### PRESENT STATUS OF ORGANIZATION IN THE PROFESSION.

It becomes apparent, at a glance, that to secure the necessary action by the Congress, or by the various legislatures on the subjects I have mentioned, chiefly by way of illustration, we are confronted by the necessity for three requisites, namely, organization, discipline and action. So far as organization is concerned, I am pleased to report that the condition is rapidly becoming satisfactory. The reorganization of the American Medical Association, with the various state associations as integral factors and with county societies as the primary units of organization, the medical profession of the whole country is, for the first time, in a condition of effective solidarity. This general scheme of organization has been supplemented by special agencies calculated to bring the full weight of the profession to bear on important public questions. These special agencies consist of a National Committee on Medical Legislation, consisting of a limited number of members, assisted by a legislative council embracing not only the National Committee on Medical Legislation, but of one member for each state and territory and for each of the public services, while this, in turn, is supplemented by a National Auxiliary Congressional and Legislative Committee, consisting of one member in each county in the United States.

### MOTIVES AND METHODS OF PROCEDURE.

And now permit me to say a few plain, very plain, words about motives and methods underlying this extensive organization. In the first place, from the day when, in our early colonial period, a few physicians gathered together, to the present when, within the limits of our confederated organizations—national, state and county—there are quite 75,000 out of the 140,000 physicians of the country, the primary motive has been, as it is to-day, a desire to promote the scientific excellence and the humane efficiency of the profession. The motive underlying the political aspect of our organization, however—the word political having no party significance whatever—requires rather more definite explanation. In the first place, in the long course of agitation touching sanitary and medical legislation, national and state, the medical profession has been held responsible for every measure, however ill considered, absurd or mischievous, that has been brought forward. On the other hand, many meritorious measures, on which the medical profession would like to have spoken, and concerning which legislators would naturally have desired the advice of the profession, have failed of passage, because the profession, not existing as a compact body, or being divided in council, or having no means of arriving at either a consensus of opinion or a concert of action, has failed to bring its proper and legitimate influence to bear on the question. This condition, it is believed, has been at least measurably remedied by the creation of the committees to which I have alluded, but whose respective duties require additional explanation. Thus, in the first place, it is the duty of the National Committee on Medical Legislation, appointed by the American Medical Association, to examine carefully into the merits of all proposed legislation relative either to the public health, to vital statistics, or to the practice of medicine, and as far as possible, secure uniformity in these provisions—all proposed legislation affecting either the efficiency, status or personal welfare of the medical profession, as represented in the public services; and all proposed legislation in any way relating either to the science of medicine or to the correlated sciences.

The results of these deliberations are then to be laid before the national legislative council, already alluded to, consisting of the National Committee on Medical Legislation, and one representative from each state and territorial medical association and one from each of the public services, namely, the Army, the Navy and the Public Health and Marine-Hospital Service. It is assumed that the findings of such a representative body can be accepted for the guidance alike of the profession and of the Congress. Accordingly it becomes the duty of the National Committee on Medical Legislation, first, to make the proper representations to the respective committees before which the various bills may be pending, and next, when deemed necessary or expedient, to communicate the necessary advice to the National Auxiliary Congressional and Legislative Committee, consisting of one member in each county in the United States. It then becomes the duty of each member of this large committee, acting under the regulations as the confidential correspondent of the national committee, to bring all and only such matters of pending legislation as may be thus referred to him, to the attention of the medical profession and to the people of his respective county, and by every honorable means—personal and political, individual and professional, private and public, direct and indirect—secure desired action thereon by his representatives in both branches of the Congress of the United States. And it is made his further duty promptly to report all such efforts on his part to the chairman of the Committee on Medical Legislation of the American Medical Association.

This scheme of organization, already effected for national or congressional purposes, is equally effective in the different states, the co-ordinating center, in such instances, being the committees on medical legislation appointed by the respective state associations, the advisory council being the district councilors, while the local auxiliaries may be the regular appointees of the national committee, which appointees are, it will be remembered, nominated by the presidents of the state associations.

In this way, and in this way only, so far as the National Committee on Medical Legislation has been able to determine, can the medical profession as a body be safely guided in its opinions and actions on legislative questions, and in this way only can such opinions be reflected effectively on the Congress. The policy is not, however, in any sense, one of "stand and deliver." It is probably true that the few dozen doctors in a county, or the few hundred in a congressional district, or the few thousand in a state, acting as a unit, might exercise a modifying influence on results; but this is a phase of the question not to be contemplated. The theory is, rather, that an explanation made by a constituent is generally more lucid and convincing than is the same explanation when made by a strange committeeman, particularly when the committeeman can not get within "earshot" of the law-maker. Aside, however, from the humor of the observation, the fact remains that advice from acquaintances, from friends, from family physicians, whose relations in life are known and of whose intelligence and disinterestedness there can be no question, is naturally enough the very advice which a conscientious congressman or legislator would gladly welcome.

The chief object that I have had in view in presenting this brief résumé of a really very important subject would be lost if, in conclusion I did not invoke your cordial co-operation and that of the entire profession in carrying this work to its fullest fruition. In this connection, let us remember that all co-operative endeavor becomes effective only when approached in a spirit of concession. The art of politics has been defined as the art of compromise; and, my friends of the profession, we, in the sense that I have attempted to define, are in politics. This fact has been recognized all over the country and in the great work of organization, with not more than two exceptions, the spirit of compromise has been so dominant that prejudices, predilections, prerogatives and even minor principles have been willingly and gladly subordinated to the greater principles for the conservation of the greater good. This spirit—the very soul of fraternity, coupled with the spirit of industry, the spirit of culture, the spirit of patriotism—must be kept in the ascendant if we, as a profession, shall maintain our just position and discharge our full duty as citizens of this great republic.

# A CONTRIBUTION TO THE STUDY OF VISUAL DISTURBANCES IN BRAIN INJURY.*

WILLIAM E. GAMBLE, B.S., M.D.
Adjunct Professor of Ophthalmology and Clinical Ophthalmology, College of Physicians and Surgeons, the School of Medicine of the University of Illinois; Assistant Surgeon (Eye Department) Illinois Charitable Eye and Ear Infirmary.
CHICAGO.

### NARRATION OF CASE.[1]

*Hospital Record.*[2]—Fred. L., was brought by patrol about 9:30 p. m., Feb. 11, 1899, with gunshot wound in the left temple, one and one-half inches back of left eye, one-half inch above zygoma (Fig. 1), the revolver having been held within a few feet of the head. Examination found the patient pale, pulse slow and full, pupils moderately dilated, cold perspiration, no focal symptoms (?); a round hole with edges blackened and inverted in the location above described. Hemorrhage severe. Can not find bullet by palpation. Next day found bullet had flattened against side of the skull, and was removed (?) by Dr. C. within a few minutes after the injury. Patient was unconscious for about 14 days; had partial aphonia.

No convulsions at any time. Summary of the pulse rate and temperature: During his hospital residence his temperature was above normal only on two occasions: on March 15, 100 F.; on March 16, 100.8 F. The pulse rate remained below normal until February 20, after which it remained normal, 72. The lowest rate, 52, was recorded February 18. No further record kept.

Diagnosed—Bullet wound of the head; concussion of the brain. Result—Cured. Discharged March 9, 1899.

*Patient's Story.*—The patient gives me the following history: For a few days after returning to consciousness he could not recognize familiar objects by sight; he did not know what the pictures on the wall were; on looking out of the window he *could not recognize* the streets or the locality. He was unable to count or name the letters of the alphabet. He was lost.

On his way from the hospital to his home he was still unable to recognize the familiar streets. He says this inability to recognize the streets lasted *only* two or three days after returning home. All other things that he saw he knew at this time. There were no *hallucinations of vision.* He was unable to call the names of the most familiar objects about the room, although toward the end of his hospital sojourn he knew the *use of them.* For example, he could *not recall the name of a* "chair," but he knew its use.

When he wanted to smoke he could not recall the name "cigar," but would indicate it by making the motions of holding and puffing a cigar. Neither the touch, taste or smell of the cigar would bring the name to his mind, but when "cigar" was mentioned to him he would immediately recognize and repeat it, but would soon forget it. The ticking of a watch or ringing of a bell did not bring back the name of the object. He would speak of a street car as a "*thing to ride in*," etc. He could not recall the names of his *most familiar friends*, but he recognized them, for example, his brother-in-law, whose name is Robert, he would call "*Lawrence*" or other names.

For several months after the injury he was unable to read printed or written words. Three months after the injury he wrote a letter to his father, which his father answered. The patient was unable to read this letter after he had written it. He says he would forget the last word on going to the next.

*Author's Findings After One Year.*—Jan. 24, 1900, he came into my service at the Illinois Charitable Eye and Ear Infirmary, complaining of difficulty with his sight. Age 28 years. An intelligent, educated German. No history of previous disease of the eyes or dimness of vision; no history of syphilitic infection or evidence of tabes.

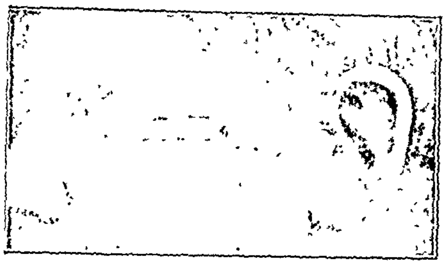

Fig. 1.—Showing entrance of bullet.

R. V. 20/20+, L. V. 20/20+. Pupils normal in size, and *reacted normally to direct light*, consensually and to *accommodation. Discs slightly* paler than normal. No diplopia present, right homonomous hemianopsia. Negative scotoma. *Intact part of the field contracted* for form and color (Fig. 2). *I searched diligently* for hemiopic pupillary rigidity, but it was not found.

He can not raise the right foot well, walks lame. Little reduction in strength of right hand (he is right-handed) as compared with the left. Right half of the body anesthetic, most pronounced in the foot. No paralysis of muscles of the right side of the face. Hearing normal in each ear. Taste on each side of the tongue unimpaired.

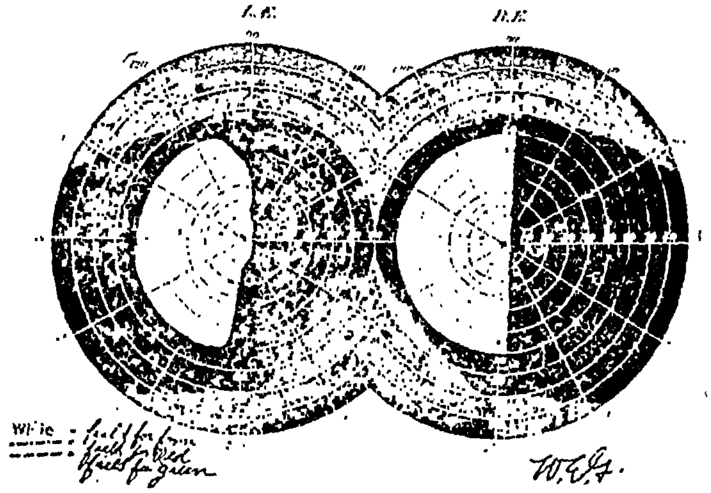

Figure 2.

He had severe headaches (not localized) for ten months after *the injury. He has difficulty in remembering proper names;* for example, he can not remember my name, although he knows me well. On handing him my card he has a little difficulty in reading it. He can not give the name of this hospital nor of the street, although he is acquainted with the locality. He writes spontaneously and less freely from dictation.

In view of the presence of hemiparesis, hemianesthesia and hemianopsia, I could not accept the statement of the physician who first saw the patient that the bullet had not penetrated the skull. Consequently, I did not agree with the *diagnosis*—"concussion of the brain"—made at the hospital. Radiographs were taken, plainly showing the bullet in the occipital region, left hemisphere (Figs. 3 and 4).

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

[1] Case reported to Chicago Ophthalmological and Otological Society, May 13, 1902.

[2] Taken from Alexian Brothers' Hospital case record.

*Condition After Three Years.*—Feb. 19, 1902, three years from date of injury, he visited me again. V. R. 20/20—. V. L. 20/20—. Pupillary action normal. Field of vision same as when taken two years ago (Fig. 2). He still has difficulty in remembering names, as, or instance, he can now give my name, although when it is written he reads it.

There is no hemiplegia or hemianesthesia, but there is paresthesia of the ball of the right foot, and especially of the second toe. He locates a "sore disagreeable feeling" in the left occipitoparietal region, about the size of a silver half dollar. He has had this feeling more or less since injury. His grasp in the right hand is greater than in the left. He is not lame nor has he any difficulty in walking.

He is a finisher and painter, and is now painting, on a scaffold, the outside of one of the sky-scrapers in this city. He tells me he has great difficulty mixing paints. He can select the color if the name is given him, but he can not give the name of the color that he wants (anmesic color blindness), and as occasionally the mixing is done on an upper floor, he has to go to the basement himself instead of sending a helper to get the "color" he desires. This is especially true at the present time with shades of color that have compound names, such as bismark-brown, yellow-ochre, burnt-umber, chrome-yellow, vandyke-brown, etc. He can now give the names, red, yellow, green, blue, without difficulty when he sees them or wishes to recall the particular color. When he began painting again after his injury he could not even do this. He performs the Holmgren test perfectly. It should be added that while he was explaining to me his difficulty in getting the name of the particular shade he saw or desired, he enumerated a long list of names of special shades without hesitation. In this list were the names I have used above.

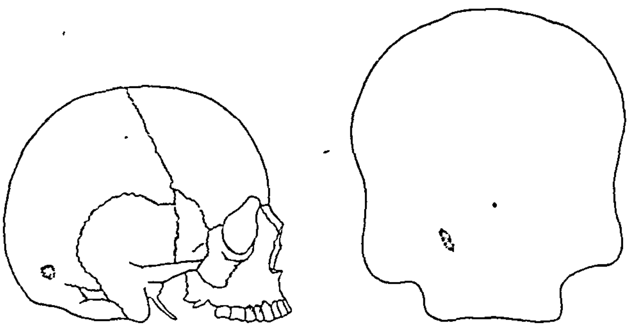

Fig. 3. Fig. 4.

Figs. 3 and 4.—Lateral and posterior views of skull, with shaded area showing bullet. Drawings accurately reduced from radiographs.

*Appearance of Optic Discs.*—In the right eye the bluish-white lamina cribrosa shows through the greater part of the optic disc, especially on the temporal side. The borders are sharply defined and the vessels but slightly changed; veins possibly a little engorged. Some connective tissue is seen at the bifurcation of the main artery, probably congenital. The left optic disc is pale, but does not have the bluish appearance of the right, and the lamina cribrosa is but dimly seen. There is some connective tissue at the bifurcation of the central artery. The outline of the margin is pronounced, with no signs of choroidal atrophy in the margin. Veins are possibly slightly engorged. No other change was observed.

*Condition After Four Years.*—Feb. 26, 1903. R. V. 20/20—. L. V. 20/20—. Field same as on last examination. Current speech seems to be about normal. When asked "Who is President of the United States?" he replied, "Garfield," and finally, after much effort and mispronunciation, got the name of the President correctly. For the last several months he has set himself to the task of increasing his vocabulary for names. By constant repetition he is slowly becoming able to retain permanently the names of the people he most often needs to address. He no longer forgets my name. He can now recall at will the names of a few of the principal streets, although to-day he was unable to give the name of one of two streets passing a shop where he has worked since last November. He carries a street directory with him and underscores the name of the street he wishes to reach. Sometimes he can remember the first letter and recognize the name when he finds it on the printed list.

While before his injury he was an omnivorous reader, he now reads at most disconnected newspaper paragraphs and letters from his father. In each letter there are words which he is unable to make out, and he usually writes his father for an explanation (alexia). The patient is of the opinion that the rate of progress from complete alexia (pure), in 1899, to his present attainment has been less during the last year than formerly. He has made no systematic effort to train this faculty. He says he has especial difficulty with long words: that seeing the left half of the word, and then, as he turns his eyes to increase his field, seeing the other half, he forgets the first, this explanation does not entirely satisfy him, but he is unable to add to it. At 15 inches from his face he is unable to keep in his eye a word longer than ¾ of an inch. At closer distance the length of the word seen is more limited. He thinks his chief difficulty is with long and (to him) unfamiliar words. Formerly he had the same difficulty with short words. By intently looking at the word which puzzles him he is usually able to read it after a time. He has had no trouble in writing at any time.

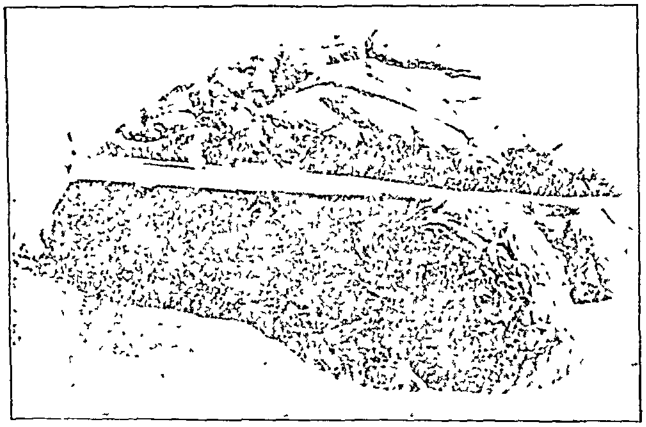

Fig. 5.—View showing assumed line of transit of bullet. The third and fourth temporal and middle convolutions suffered.

In determining the probable localization of the lesion, I have had the good fortune to secure the co-operation of my friend and colleague, Dr. William T. Eckley, professor of anatomy in the College of Physicians and Surgeons, the School of Medicine of the University of Illinois. Dr. Eckley also secured the assistance of Prof. Harry E Santee. Their methods and conclusions are given below.

*Anatomic Report.*—"With the able assistance of Dr. Harry E. Santee, we are prepared to submit the following report, in which we duplicate to the best of our ability, on a cadaver, the line of transit and brain tissue traversed by a bullet in the above case.

"As indicated by the skiagraphs submitted by you to us, the bullet now occupies in your patient a space three-quarters of an inch above and one inch and a quarter to the left of the external occipital protuberance, in the left cerebral hemisphere in contact with or very close to (probably ⅛ inch) the skull in this region. A scar on the patient, just above the zygomatic arch and in the junctional angle of the frontal and zygomatic processes of the malar bone, marks the place of entry of the bullet. On a cadaver's head, conforming in measurements to the head of the patient, we located the entry of the bullet and its resting place, by comparison with head of patient and skiagraphs; and by trephining through the skull at these extreme points, succeeded in passing a steel spike ¼ inch in diameter through the brain in the probable line followed by the bullet. The hypothetical line of transit passes just above, but does not touch the superior border of the petrous part of the temporal bone; and this being the only structure in the area under consideration, capable of producing deflection of the missile, we concluded the same followed a straight line, and on this assumption we venture to enumerate the brain regions necessarily traversed by the bullet.

"(a) The greater part of the third temporal convolution, in which the so-called naming center is located, was destroyed.

"(b) The fourth temporal convolution is almost destroyed, the upper part especially.

"(c) The anterior end of the inferior occipital convolution is bruised.

"(d) The outer surface of the middle occipital convolution is penetrated.

"(e) The perpendicular fasciculus of association fibers was in part cut off. This band of long association fibers, while of doubtful function, extends from the inferior parietal to the second and third temporal convolutions; and also joins the superior with the middle and inferior occipital convolutions and with the fusiform gyrus of the temporal lobe.

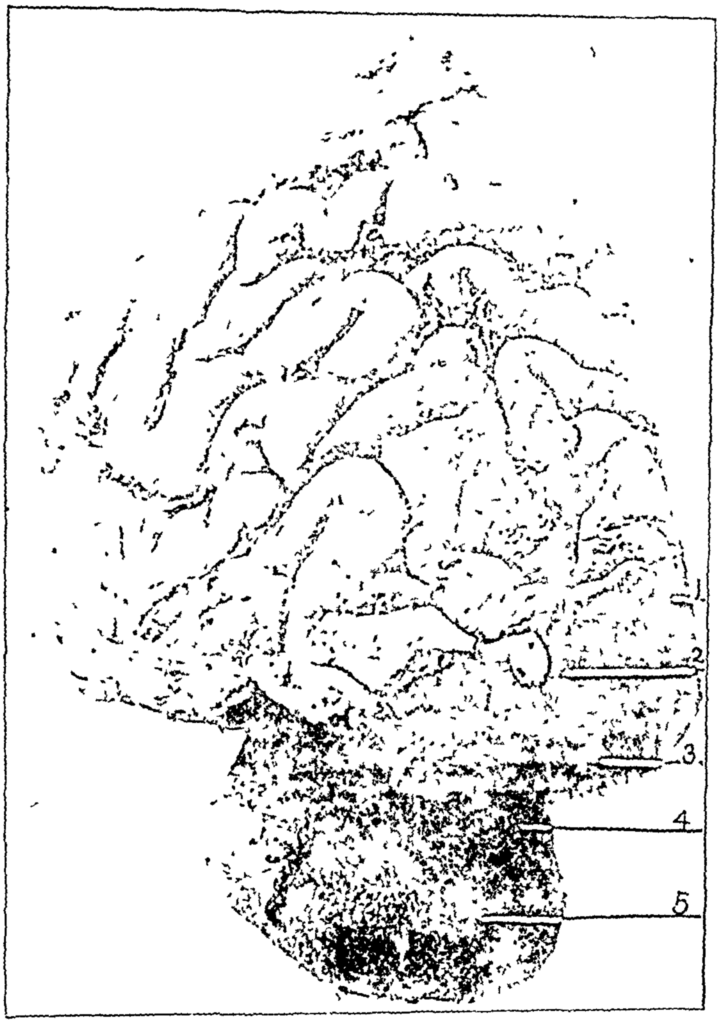

Fig. 6—Showing distance of posterior part of wound from the cuneus, about one inch. 1. Sup. oc. convolution. 2. Middle oc convolution 3. Inf oc convolution 4 Transverse fissure 5 Cerebellum.

"(f) The association fibers between the tentorial and convex surfaces of the occipital lobe have been in part cut off.

"(g) The inferior longitudinal fasciculus connecting the temporal and occipital lobes, thus associating the center of hearing and visual memory respectively, may have been cut off or injured by concussions."

### ANALYSIS OF FINDINGS.

This lesion, not involving the internal capsule (three-fourths inch away), the hemianesthesia and hemiplegia, principally confined to the right leg, being temporary, could be accounted for by hemorrhagic disturbance of the tracts leading from the occipital cortex as they pass forward to enter the internal capsule; and not by permanent lesion, the hemianopsia in this case being due to severance of *all the visual* bundle of radiations of Gratiolet in this hemisphere.

The *mind-blindness* can readily be accounted for by general circulatory and consequent nutritional disturbance of the brain resulting from the injury.

The *verbal amnesia* would seem to be of the visual type. It can not, however, clearly be classified as "visual aphasia," as described by Freund[1] and others, because names of objects seen are not recalled by aid of other senses. For example, the smoking of the cigar which would call into co-operation with sight the senses of touch, taste and smell, did not bring back the name Listening to a watch or a bell did not bring back the name "watch" or "bell." However, his loss of memory for substantives, especially proper nouns, has been classified as visual aphasia by some authors, the name being immediately recognized when heard but soon forgotten.

It is a significant fact that in 25 cases of aphasia in various forms, in otitic abscess of the left temporal region, collected by Merkens,[2] the only symptom common to all, was visual aphasia. Oppenheim[3] says this symptom "appears to be caused by lesions at the border of the left occipital and temporal lobes, and so extensive as to divide the conducting tracts leading from the posterior lobes to the center for tone pictures." C. K. Mills[4] teaches that there is a concept area for names in the mid-temporal region, probably in the posterior fourth of the third temporal and the occipital (left) in this region, which he calls the "naming center."

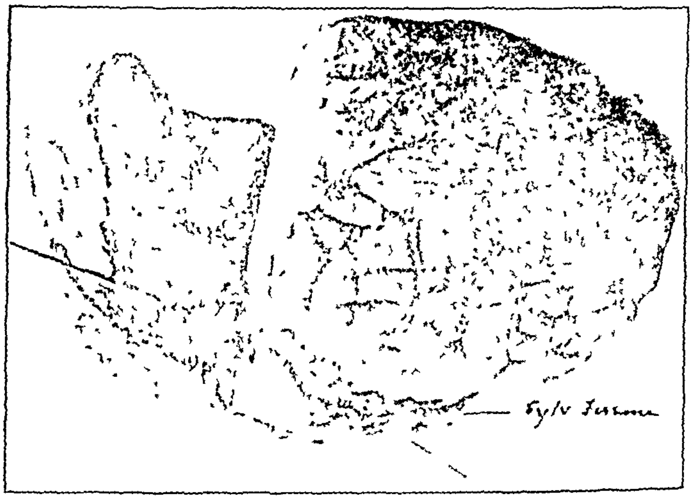

Fig. 7—The needle represents (a) course of bullet through third and fourth temporal convolutions; (b) relation of course of missile to descending and posterior horns of lateral ventricle, (c) relation to radiations of superior longitudinal fasciculus, optic radiations and inferior longitudinal fasciculus

It can not be definitely determined by the findings in this case whether the verbal amnesia is a result of destruction of the greater part of the cortex in the third and fourth temporal convolutions (posterior) and injury to the cortex of the anterior end of the inferior occipital convolution; or of subcortical lesion in the middle occipital convolution, extending backward nearly or entirely through it or a result of all the lesions.

However, in view of the fact that there is little or no evidence heretofore brought forward of subcortical lesion in the inferior occipital convolution producing this symptom; and on the other hand, much

4. Mills: The Journal A. M. A., October, 1902. Mills and J. W. O'Connell: Jour. of Nerv. and Mental Dis., vol xx, 1895

evidence has been accumulated showing that cortical lesion in the third and fourth temporal convolutions produces this symptom, this case furnishes strong corroborative evidence in favor of the teaching of Professor Mills and others, that there is a concept area for names in the third or fourth temporal convolutions and anterior part of inferior occipital convolution, or in all.

The ability to increase his vocabulary for proper names shows that there are other cells that have this function, though undeveloped, and for the reason given below in connection with word-blindness, this undeveloped word center is probably in the right hemisphere.

*Amnesic Color Blindness.*—The patient was unable to name any color at sight for many months. At the present time (four years after date of injury) he is unable to give the names of particular shades, such as bismark-brown, chrome-yellow, etc., although being a painter, if given the name he can select any shade that he uses, but he can name the ordinary colors when he sees them, such as brown, yellow, etc. His color sense is normal, as he performs the Holmgren test perfectly. Therefore it is strictly an aphasic symptom, and has nothing to do with disturbance of the color sense.

The presence of this symptom in lesion of the left middle occipital and third and fourth temporal convolutions proves conclusively the correctness of Willbrand's[5] supposition that the lesion must be in the left hemisphere in a right-handed person. But in addition it shows this to be not the whole truth, for his partial reacquirement of this function by persistent training during a period of four years, can be explained only as an education of an undeveloped center in the right hemisphere for the same reasons as those given below for the reacquirement of names and the reacquirement of the ability to read. This lesion is evidently produced by severance of the path leading from the center for color vision at the bottom of the calcarine fissure (Henschen),[6] anteriorly to the speech center.

*Word-Blindness.*—The pure word-blindness, according to the patient's explanation is probably partly a forgetfulness of parts or the whole of a word preceding the part in mind—a type of verbal amnesia. This aphasic disturbance was complete for several months (more than three months). Improvement has been gradual until at the present time he can read, although with difficulty. The gradual recovery from this aphasic condition can not be accounted for by a reparative process taking place in the left middle occipital and third and fourth temporal convolutions, the bullet being larger than 22-caliber.

Phelps[7] reports a case of gunshot wound of the brain, in which thirteen years afterward the bullet tract was converted into a membranous canal. Doctors Sanger Brown[8] and Schaefer found, six months after removing the occipital lobe of a monkey, that the cut surfaces had remained unchanged, the edema *ex vacuo* taking the place of the lost part. It is hardly necessary to add that evidence is lacking of reparative process in lesion of nerve tissue in brain and cord.

We are compelled to assume that other specialized nerve cells have taken on this function, and from our knowledge of the bilateral nature of other functions of the brain it is reasonable to assume, according to Bastian's[9] teaching, that the right hemisphere has an undeveloped word center which is capable of education, contrary to the views of Dejerine[10] and Lichtheim that only the left hemisphere is concerned in word-blindness. In the three other cases of pure word blindness (Dejerine,[10], Redlich and Wyllie) so far reported, in which autopsies were obtained, the lesion found in each case was in the white substance in occipital region (left) together with damage to lingual fusiform hypocampal gyrus and cuneus. In these cases the cortical region injured is destruction of the greater part (posterior) of the third and fourth temporal convolutions and the bruising of extreme anterior end of left inferior occipital convolution, the cortical area common to this case and another case reported being the fusiform gyrus.

Therefore, in this case, it is altogether probable that the lesion causing this alexia is mainly due to the injury of the white substance in the occipital region, involving the lower part of the inferior longitudinal fasciculus (Dejerine[10]) and not due to direct cortical lesion.

*Dyslexia.*—The distaste which the patient experiences for reading (dyslexia) is partly due to the great reduction of the field resulting from the hemianopsia and from the concentric contraction of this half field to 50" for form (20" for red and 10" for green); and partly due to partial word-blindness and also to fatigue which comes from developing a function in the right hemisphere comparable to the discomfort evinced by a child in learning to read.

*Optic Atrophy.*—There being no history of previous severe illness nor dimness of vision or other ocular trouble, nor evidence of tabes nor syphilitic infection present, it must therefore be assumed that the gunshot wound is the cause of the change in the discs. Primary atrophy of optic discs, if we adhere to the doctrine of the neuronic theory, is almost inexplicable when the lesion is behind the central ganglia, as it is in this case. The "indirect"[11] theory, lately put forth is the only explanation so far offered.

*Prognosis.*—The unusual fact of the toleration of the bullet by the brain for a period of four years may be due to its present location, being possibly on the tentorium. The irritation of this membrane may have produced proliferation of the connective tissue about the bullet, encysting it. If this be true, for this reason the prognosis in this case is good. Surgical interference would probably improve prognosis.

### CONCLUSIONS SUGGESTED.

The findings in this case suggest the following conclusions:

1. A cortical lesion the size of a 32-caliber (?) bullet, involving the greater part (posterior) of the third and fourth left temporal convolutions and bruising of extreme anterior end of inferior occipital convolution, and a subcortical lesion penetrating the middle occipital convolution at the same level, produces verbal amnesia, especially for names of objects seen and having been seen, particularly those which have proper names (concrete nouns), and for names of colors, especially names of special shades, such as bismark-brown, etc. (amnesic color blindness), and pure word-blindness (alexia), which may be in part a form of visual verbal amnesia.

[9] Bastian: Allbutt's System of Medicine, vol. vii, p. 437.

[10] Dejerine: Quoted from Swanzy, "A System of Diseases of the Eye," Norris and Oliver, vol. iv, p. 561.

[11] Barker: The Nervous System, p. 18.

2. Verbal amnesia is a result of lesion in the cortex of third and fourth temporal convolutions, left hemisphere and injury to cortex of anterior end of inferior occipital convolution.

3. The amnesic color blindness and alexia result from subcortical lesion in left middle occipital convolution.

4. The reacquirement of these functions in a man 28 years of age is a slow and tedious process of education of the specialized though undeveloped cells of the right hemisphere, requiring years for even partial accomplishment.

5. Injury to the optic radiations of Gratiolet may produce negative scotoma, contrary to the teaching that such a lesion produces positive scotoma.

6. Primary atrophy of the optic discs occurs in lesions of the left tempero-occipital region.

## DISCUSSION.

Dr. H. T. Pershing, Denver—It is somewhat precarious to infer the place of a lesion from an attempted reproduction of it on the cadaver of another person. From its clinical features, I think the case was one of subcortical visual aphasia. The fact that the patient could write showed that his visual memory was good, but the fact that he could not read what he had written showed that there was an interruption of the association fibers. This explanation would also account for his inability to recall nouns, especially proper nouns, because, according to the best theory we have to offer, a noun is recalled by the visual image of the corresponding object. My opinion, therefore, is that the case was one of subcortical visual aphasia, due to a lesion in the immediate vicinity of the angular gyrus.

Dr. H. T. Patrick, Chicago—I feel inclined to support Dr. Pershing's view. I understood from Dr. Gamble's paper that the last examination of the patient's eyes made recently showed a vision of 20/20 in either eye, and yet there was double optic atrophy. How does he reconcile these statements? Furthermore, how could this injury cause double optic atrophy? The course of the projectile, as traced by Dr. Gamble, would hardly account for the motor and sensory disturbances in the right lower extremity. In order to account for those symptoms, the bullet would have to go a little deeper and start a little further forward, which would be a much simpler explanation than to invoke the aid of disputed points in anatomy and physiology or theories that are as yet unproved. It has been shown by Horsley and others, especially since recent wars, that the injury inflicted by a projectile passing through the brain is not accurately represented by the track of the bullet. The latter has an explosive action, and this gives rise to widespread injury which is more or less in proportion to the velocity of the projectile. The injury inflicted by a bullet passing through the brain is not the same as that resulting, for example, from excision of a certain cortical area. By a rapidly moving bullet, as just stated, the brain is somewhat injured, not destroyed, to a certain extent outside the course of the projectile. Such an injury does not involve the question of the reuniting of nerve fibers or the regeneration of nerve cells. It simply involves a reparative process in the immediate neighborhood of the injury, such as occurs after traumatism or embolism or hemorrhage. There is only a partial injury to the brain tissue, and it is usually followed by at least partial repair. It is not necessary to invoke the theory of the re-education of latent nerve cells or centers in the adult.

Dr. J. H. McBride, Los Angeles, Cal.—About thirty years ago there was reported in London the case of a right-handed child that suddenly became aphasic, indicating a lesion in the left motor speech center. Within a year, speech was entirely recovered. Two years later there was another attack of aphasia, which was permanent. The child died six months later, and two lesions were found in the brain, one involving the third left frontal convolution and the other the third right frontal. In 1890 there was admitted into the Milwaukee Hospital a man who was supposed to be suffering from chronic epilepsy. He stated that twenty-seven years before he had been shot in the eye. The man died, and at the autopsy the bullet was found under the left temporal bone. It had lodged in the second left temporal convolution and gradually gravitated to the point where it was found.

Prof. W. T. Eckley, Chicago—Speaking on the basis of the examination that Dr. H. E. Santee and I made, the anatomic side of the discussion of this valuable contribution will give a brief summary of the known anatomy and physiology of the temporo-occipital region, looking to the pathologic possibilities incident to disease or trauma. We shall consider the commissures, the association fibers, and the sensorial cortical centers, which latter receive impulses from corresponding peripheral regions, and give origin to audition, olfaction, gustation and vision.

*The commissural fibers connect portions of opposite hemispheres, forming definite structures*—the corpus callosum, the anterior commissure and the hippocampal commissure.

*The corpus callosum* connects both similar and dissimilar parts in all regions of the hemisphere except the olfactory bulbs and the antero-inferior portions of the temporal lobes. The anterior commissure, supplemental to the corpus callosum, connects the two olfactory lobes and portions of the temporal lobes. The hippocampal commissure connects the uncus, optic thalamus and hippocampus major of one side with similar structures of the opposite side.

*Association fibers in general connect* parts of the cortex on the same side of the hemisphere. Short association fibers connect convolution with convolution; long association fibers connect lobe to lobe. The long association fibers are the cingulum, fornix, uncinate fasciculus, superior longitudinal fasciculus, inferior longitudinal fasciculus, occipito-frontal fasciculus, and perpendicular fasciculus.

*The cingulum* is in the falciform gyrus and almost completely surrounds the corpus callosum. It associates the frontal lobe and uncus. The fornix connects the corpus albicans and thalamus with the uncus and hippocampus major. The uncinate fasciculus arches over the stem of the sylvian fissure, connecting the uncus with the frontal pole and orbital convolutions. Lesions in cingulum, fornix or uncinate fasciculus produce disturbances in smell, because they are connected with the rhinencephalon.

*The superior longitudinal fasciculus*, on the outer surface of the foot of the corona radiata, connects the frontal temporal and occipital lobe. It passes over the insular region and at the posterior end of the sylvian fissure bends around the putamen and passes to the temporal lobe. It sends numerour radiating fibers into the occipital lobe. This fasciculus associates the motor speech center with the visual and auditory memory centers. If it is destroyed, the patient can see and hear perfectly and recognize things seen and heard, but he has no power to express in words his visual and auditory memories.

*The inferior longitudinal fasciculus* extends along the whole length of the temporal and occipital lobes, uniting the auditory and visual memory centers. In the occipital lobe it is to the outer side of the optic radiations, from which it is to be distinguished by the greater coarseness of its fibers.

*The fasciculus occipito-frontalis* is between the cingulum and superior longitudinal fasciculus, extending from the cortex of the entire frontal lobe to the occipital lobe, where its fibers diverge, fan-like, and enter the descending and posterior horns of the lateral ventricle.

*The perpendicular fasciculus* extends from the inferior parietal convolution to the second and third temporal convolutions anteriorly; posteriorly, it joins the superior, middle and inferior occipital convolutions with the fusiform gyrus of the temporal lobe.

*The auditory sensory center* is in the transverse temporal gyri and third and fourth fifths of the superior temporal convolution. It is represented peripherally by the cochlea, and impulses of hearing reach the auditory sensory center over the cochlear path.

*The auditory memory center* is intimately associated (1) with the auditory sensory center, by short association fibers; (2) with the motor speech center, by the superior longitudinal fasciculus; (3) probably, with the naming center, through a group of association fibers.

*The olfactory center* is probably in the mucus. It is represented peripherally by the schneiderian membrane. Impulses of smell reach the uncus through the fibers of the olfactory tract, cingulum and uncinate fasciculus.

*The gustatory center* is probably in the cortex of the hippocampal convolution, posterior to the olfactory center. It is represented peripherally by the end organs of the glossopharyngeal and chorda tympani nerves. Impulses of taste reach the center through the medial fillet and internal capsule.

*The visual sensory center* is in the cuneus and lingual convolution, on the mesial surface of the hemisphere, and extends somewhat into the convex surface of the occipital lobe. Its peripheral representative is the retina, and impulses here originating reach the higher visual sensory center, in the cortex of the cuneus, via the optic nerve, tract and radiation. The visual sensory center is connected to the visual memory center by short association fibers.

*The visual memory center* is in the angular and occipital convolutions. It is associated with the visual sensory center by short association fibers, and with the motor speech center, in the central gyri and inferior frontal convolution, through the superior longitudinal fasciculus. Injury of the visual sensory center produces blindness. Injury of the visual memory center produces mind blindness. Destruction of the tract, associating the visual memory center and the motor speech center produces sensory aphasia.

Let us now analyze the sensorial cortical centers in the occipital and temporal lobes, with reference to destruction of (*a*) the sensory center; (*b*) the memory center; (*c*) the tract of association fibers connecting several memory centers with the motor speech center. If the visual sensory center is destroyed, there is blindness in the opposite eye. If the visual memory center is destroyed, vision remains, but the patient has no power to recognize through seeing. If the tract connecting the visual memory center with the motor speech center is destroyed, vision and recognition of things seen will be perfect, but the patient will be unable to express in words his visual memories. If the auditory sensory center is destroyed, there is loss of hearing in the ear of the opposite side. If the auditory memory center is destroyed, the patient hears, but there is failure of recognition, through hearing. If the tract connecting the auditory memory center with the motor speech center is destroyed, hearing and recognition of things heard will be perfect, but the patient will be unable to express in words the auditory memories. In the light of analogy there must be, linked to the olfactory and gustatory centers, corresponding olfactory and gustatory memory centers. If the olfactory sensory center is destroyed, there is loss of smell in the nose of the corresponding side. If the olfactory memory center is destroyed the patient smells, but can not recognize through smelling. If the tract connecting the olfactory memory center with the motor speech center is destroyed, smelling and recognition of things smelled will be perfect, but the patient will be unable to express in words his olfactory memories. If the gustatory sensory center is destroyed, there will be loss of taste. If the gustatory memory center is destroyed, the sense of taste is perfect, but the patient can not recognize things tasted. If the tract leading from the gustatory memory center to the motor speech center is destroyed, taste and recognition of things tasted will be perfect, but the patient will be unable to express in words his gustatory memories.

In the interesting clinical case under discussion, the patient could see and recognize things seen; hear and recognize things heard; smell and recognize things smelled; taste and recognize things tasted. Therefore, the respective sensory and memory centeres of vision, audition, olfaction and gustation were unimpaired. The patient, however, could not express in words, visual, auditory, olfactory and gustatory memories. Therefore, there must have been interruption in the long association fibers connecting the cortical memory centers of these special senses with the motor speech center; and the injury must have been to the radiating fibers in the occipital lobe where the superior longitudinal fasciculus turns forward into the temporal lobe, around the putamen. In view of the symptoms —visual, auditory, olfactory and gustatory aphasia—is not the easiest explanation of this group of symptoms to be found in the assumption of a common naming center, interposed somewhere between the motor speech center and the cortical memory centers previously mentioned?

DR. W. E. GAMBLE—The lesion producing the alexia is probably the subcortical injury in the left middle occipital convolution involving the inferior longitudinal fasciculus, and not the cortical lesion in the third and fourth temporal convolutions. I fail to see on what known or supposed physiologic basis Dr. Patrick assumed that the lesion in this case is higher up than Dr. Eckley has demonstrated, that is, involving the region of the angular gyrus. This region is held by Bastian and Gower to be the center for visual memories, while the later clinicopathologic work of Henschen leads him to the conclusion that the whole convex surface of the occipital lobe has this function. Wilbrand, Nothnagel and others believe that the whole occipital lobe, except where the center of vision resides, stores up visual memories. In my case the visual memories are intact, with the possible exception of alexia. In answer to Dr. Patrick's question: "How can your patient have optic atrophy and still see 20/20 with each eye?" At first thought such a statement would seem a paradox. However, by reference to the diagram of the field of vision (Fig. 2), it will be seen that his half fields are concentrically contracted for form to 50 degrees, which shows that a large part of the optic nerve (peripheral fibers) has lost its function. The maculopapillary bundle has remained intact, which accounts for the good central vision. I do not share in Dr. Patrick's difficulty of understanding how the patient had temporary hemiparesis and hemiplegia, especially confined to the right foot, in the lesion described. As I stated in my paper, the tracts passing from the occipital cortex to the internal capsule were more or less injured by the hemorrhage, not destroyed by the bullet, the internal capsule not having been injured.

# A CASE OF PERFORATING WOUND OF BOTH CEREBRAL HEMISPHERES.*

W. S. LINDSAY, M.D.
TOPEKA, KAN.

Last November, while attending a meeting of our county medical society I was summoned, in company with Drs. McClintock and Bowen, to a hotel near by in which a guest of the house was said to have attempted suicide. We found a young man about 19 years of age writhing on the floor with a bloody wound on the right temple, the result of a revolver shot fired about five minutes previously.

The hemorrhage was not great, but to prevent its becoming greater we tried to keep the patient quiet till an ambulance should arrive. In this we were not entirely successful, for he succeeded in getting up. He seemed very reticent on being questioned, although he talked enough to show mental coherence. We discovered that he had on only one cuff, whereon the patient informed us distinctly that the missing cuff was in his overcoat pocket, where it was found. Thus within a few minutes after the wound was inflicted, full mental operation was apparent, the senses of sight and hearing were normal, comprehension of spoken language was complete and the ability to frame and express a correct reply unimpaired. There was also manifest co-ordinate movements.

Examination at the hospital an hour later showed what was in effect a perforating wound of the brain, for the bullet, which was from a 32-caliber revolver, was found outside the skull on the left side, nearly opposite the point of entrance, which was one inch and a half superior and one inch and a half anterior to the meatus auditorius on the right side.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

Dr. Bowen dressed the wounds at Christ's Hospital, and the patient made an uneventful recovery, at no time showing signs of impairment of brain function, leaving the hospital on the fifteenth day seemingly as well as ever.

March 17, four months after the injury, I examined the patient and found that on leaving the hospital the patient began the study of telegraphy, that he now takes twenty-five words per minute, and expects to take a position with a railroad company. Examination for symptoms of sequelæ was entirely barren of results, except that I found an unusual redness of the face. This had been a characteristic before the wound, and was simply exaggerated afterward. There had been no head pains, no flushing of the face, no defect of any sense and no interference with ideation.

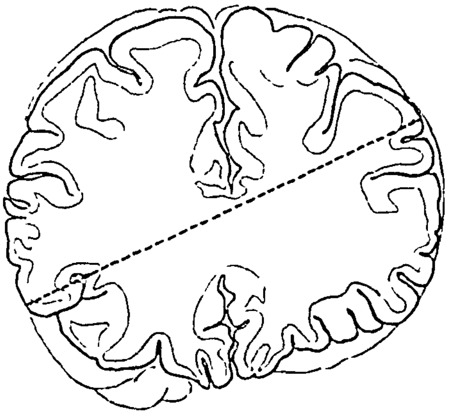

Fig. 1.—Dotted line shows line of wound through hemispheres.

By careful measurements I have prepared a section of a brain showing the track of the ball as nearly as may be. This, you will observe from the illustration, passes through the forebrain from a point in the anterior operculum on the right side to a point in the middle frontal gyrus on the left side, being about one inch higher at the point of exit.

Following this line of puncture we observe destruction of cortical cells of the third frontal convolution on right side, destruction of continuity of fibers of the fronto-cerebellar tract, which is composed of axones from the pyramidal cells of the prefrontal lobes whose course is downward and backward through the anterior part of the internal capsule and having connection through the nucleus of pontis with fibers from both cerebellar hemispheres; also association fibers representing the axones of collaterals of nerve cells connecting the cortical cells of the frontal lobe. We see also destruction of the anterior part of the corpus callosum, whereby the continuity of commissural fibers is broken; also a break in the fibers constituting the cingulum which connect the roots of the olfactories; also destruction of fibers connecting frontal and temporal lobes; thence a severing of nearly corresponding fibers in the left hemisphere.

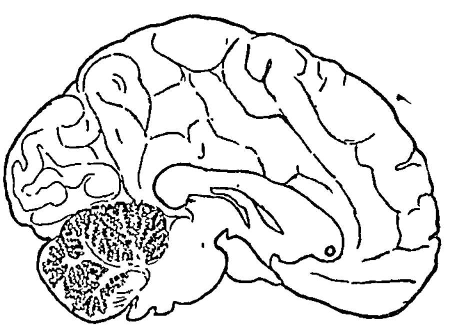

Fig. 2.—Dot shows where the ball passed through the anterior callosum.

From the investigations of Reil, Arnold, Meynert and others, we have come to recognize in the apparently homogeneous white matter of the brain fibers which constitute lines of communication in a variety of ways, till it has been said that each cell of the brain cortex as well as the basal ganglia is connected with every other cell by continuous or contiguous fibers which render this multiplex organ of ideation, motion and sensation a perfect entity. What, then, can be more important in brain functioning than the normal condition of association, commissural and inhibitory fibers primarily related to the temporal and frontal lobes of the cerebri?

We recognize the apparently profligate supply of many essential parts in nature, as seen in the pollen of our western cornfields, and in the elements of reproduction of animal life. and it has been argued that this same bounteous provision gives us such an abundance of cortical cells that many may be lost without appreciable loss of function. But can we apply this train of reasoning to a mass of cable lines extending quite across a section of the forebrain?

The surgical history of the War of the Rebellion shows a few cases of perforating wounds of the head with recovery, but so far as I can discover, nearly all have been pensioned, with a rating of total disability. These disabilities are, however, loss of vision, motor paralysis, eclampsia or vertigo, and none can be shown to be due to destruction of associating or commisural fibers.

In the case which I report, the lesion might reasonably be expected to cause defects in the association of concepts and ideas, from hindrance of functioning of fibers passing through the centrum ovale; paraphasia from lesion of the tract between the temporal and frontal lobes, defect of the sense of smell from lack of connection between olfactories, and some disturbance by reason of lesion of fronto-cerebellar tract.

I appreciate that extensive lesions in the white matter of the frontal lobes have occurred without producing symptoms, but from a theoretical standpoint, that such a lesion as I have described should occur without loss of function seems incomprehensible.

## DISCUSSION.

Dr. H. T. Pershing, Denver—Did the wound on the left side show any considerable opening in the bone?

Dr. Lindsay—There was a larger opening at the point of exit.

Dr. F. Savary Pearce, Philadelphia—Dr. Lindsay's case reminds me of one which I saw with Dr. Laplace of Philadelphia this winter. The patient was a woman, who made an attempt to commit suicide by shooting herself in the temple, the bullet emerging on the opposite side of the skull, passing through both frontal lobes. The injury was not followed by loss of consciousness nor by any other untoward symptoms, and the woman made an uneventful recovery.

Dr. H. G. Brainard, Los Angeles, Cal.—In discussing a case of this kind, we are handicapped unless the exact track of the bullet has been verified by an autopsy. It is well known that the projectile does not always follow a direct line. Furthermore, with such a rapidly moving body, it is impossible to estimate how much of the injury is due to the passing of the bullet, and how much to the resulting injury and hemorrhage.

Dr. Albert E. Sterne, Indianapolis—I see a considerable number of injuries of this class, penetrating and otherwise, and I must confess, like Dr. Brainard, that some of the results are certainly surprising. We occasionally see cases of penetrating wounds of the skull where the appearances indicate that the bullet traversed directly from one opening to the other, and yet at autopsy we find that such was not the case.

The peculiar construction of the skull is apt to cause deflection of the bullet, but this does not occur when a solid weapon, like a sword or knife, is used. There are numerous instances on record of penetrating wounds of the skull having left very few symptoms. The records of the War Department are full of such cases, in which men who were shot through the head walked unassisted to the rear. I recall one case which created considerable excitement in Indiana, and which had great forensic importance. A man was accused of killing his wife by shooting her through the head, the course of the bullet being very similar to that in the case reported by Dr. Lindsay. The statement was made in court that after the woman was shot she got up, put her arm around her husband's neck and talked with him. Her dead body was subsequently found outside the house, on the threshold of the back door. I was called to testify in the case, and the question of brain localization played an important rôle. To this day, the guilt or innocence of the man is an unsettled question to many who followed the details of the case. The assertion was made by the state that the woman could not have walked nor talked after the receipt of the injury. In the case reported by Dr. Lindsay, the fact was lost sight of that the actual injury to the brain substance by a rapidly moving projectile is not nearly so great as where the passage of the projectile is slow. The velocity of the bullet is so great that it does not force the elastic brain tissue before it, but pushes it aside, and if there is no secondary suppuration or softening, and the hemorrhage is not excessive, the amount of damage may be comparatively slight. We sometimes see curious results after injury to the spinal cord, in connection with which we would be led to believe that the symptoms would be absolutely sure and infallible. A little over a month ago I saw a man who was shot through the left lung, two inches above and three inches to the outer side of the left nipple. The bullet passed through the lung and lodged to the right side of the spinal cord, just beneath the lateral process of the seventh dorsal vertebra, where I found it at the time of the operation. As the result of his injury, the man was completely paralyzed as to motion and sensation from that point down. The line of demarcation was absolute. There was total motor paralysis, total sensory paralysis, incontinence of the bowels and bladder, and not a single reflex could be elicited; no foot clonus, no cutaneous nor cremasteric reflex. I gave it as my opinion that the projectile, which was a 38-caliber bullet, had severed the spinal cord. At the operation we found the bullet in the spinal canal, but the cord itself was not interrupted; it was merely pushed to the left side by the bullet. The symptoms in this case, as compared with the actual lesion, were contrary to all my experience and teaching. The man was injured Feb. 7, 1903, operated on February 21, and died eight days later. At the autopsy, a section of the cord, including the bullet and the seventh, eighth and ninth spinous processes were removed, and they formed one of the exhibits in the case. The lungs were the seat of a double pneumonia. The coroner ordered the autopsy on my absolute refusal to grant a death certificate unless it was done. This case is merely alluded to, to illustrate that even in conditions of spinal injury we can not always definitely state the extent of damage done. In the brain, injuries are even less accurately determinable.

DR. W. S. LINDSAY—In my case, numerous fibers were destroyed, it seems, without producing apparent loss of function. In answer to Dr. Sterne, it is fair to say that the area of injury is not limited to the actual size of the projectile; the injury no doubt extends beyond the actual path of the bullet, and that fact makes it all the more remarkable that there was no loss of function in this case.

---

A New Method of Sharpening Knives.—A German experimenter named Bernhard, says the London *Lancet*, quoting the *Engineer*, has discovered that aluminum may be used for putting an edge on fine-cutting instruments. He found that when steel was rubbed on it the aluminum disintegrated with the formation of a powder of a somewhat greasy nature which clung to the steel with great tenacity and assisted in cutting away the hard surface of the metal.

# A CLINICAL STUDY OF EPILEPSY.*

J. G. BILLER, M.D.
CHEROKEE, IOWA.

The light which science has thrown on this subject is so slight that to-day we are almost blindly groping in the dark, and those of us who come in contact with this fearful malady reach out our hands and grasp first one object then another, hoping that we are going to find the match whose tiny spark may finally illuminate the darkness about us. We can not help believing that with our increased knowledge of the secretions and excretions of the various glands of the body and the changed conditions of the blood from these and other sources, coupled with our better understanding of the nervous system, that we must to-day be in close proximity to the source of light.

I have no intention of wandering into the clouds of speculation and theory, but wish to speak of a few things that I think important in our present darkness, well aware that further light may relegate them to the rubbish pile as useless and unnecessary.

My first experience in epilepsy was in early boyhood; one of my playfellows, who was a strong, bright vigorous boy, began having peculiar spells that increased in frequency and violence till he became an object of fear to the children with whom he played, and was finally tossed on the shores of life a battered, hopeless, intellectual wreck. I remember asking the question then which I have so often asked myself in later years, "what makes him do that?"

It is well for us to continue asking this question and to search diligently for answers to it, for it is our knowledge of the cause or causes that enables us to benefit these unfortunates with our care and treatment. Our search for the cause may not be successful, then we are forced to return to our time-worn battlements and say that it is due to an easily excited or unstable condition of the cortical cells. "Why are these cells in this condition?" is our next question. When we are able to answer this, we will have arrived at a position from which we can observe the underlying causes of epilepsy, and begin to handle it in an intelligent and scientific manner.

Of course this instability may not always be due to the same thing, and to attempt to define or explain the various factors will simply be leading us into the wilderness of theory, where I do not care to wander just now; whatever may be at the bottom of this condition the fact remains that in the epileptic we have a cortical cell that is unstable and easily excited; so much does it resemble the cells of infancy in its response to irritation or stimulation, that we can rationally look on it as an immature cell, and by comparing the epileptic seizure with the convulsion of the infant we may observe facts that will be useful in treating the former. How well we know what things to look for in the ordinary infant; when it has a convulsion, some peripheral irritation or systemic poisoning is undoubtedly the cause; and the stomach, bowels, kidneys, prepuce, nose and ears are all examined. Failing here, we inquire as to exposure to heat, cold, or contagious or infectious disease, and somewhere among these we are almost sure to find the source of trouble. As it is here we find the exciting cause of convulsions in infants, so it is here we so often find it in the epileptic: for I believe that many cases of epilepsy are nothing more than the simple convulsions of infancy and childhood, where the cause has been overlooked or neglected till the epileptic habit has been formed.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

It is for this reason that it is of such importance to early recognize the possibility of convulsions or peculiar spells (as they are so often called) of infants or young children being epileptic, and especially if there be a history of epilepsy in the family. Too often we allow these children to go without much attention, thinking it is nothing more than some habit or trick of childhood, and will pass off after a time. Frequently these cases are spoken of to the busy general practitioner when he is called to see some other member of the family, and he, occupied as he is with his principal patient, thoughtlessly says: "Oh, that will not amount to anything," or, "The child will outgrow it," and the case is neglected until we have a well-marked epilepsy on hand. I have seen enough of this to make me at once interested in any child that has spells. It is in these early cases that I have had what I consider good results from treatment. I am well aware that it may truthfully be said, that these may not be epileptics and probably would have recovered without treatment. It is hard to define just what is epilepsy and what is not; but if a child has a history of spells of unconsciousness, no matter however brief, that occur at intervals and has had an epileptic ancestor or relative, however remote, we have good ground for considering the case of epilepsy and treating it accordingly, instead of awaiting further developments, for by the time it has developed so that our diagnosis is assured it may be too late for the best results from treatment.

I probably learned as much from the first case of epilepsy I treated as from any case I ever had under my care. It was a boy 3 or 4 years old who made a perfect recovery after having taken large doses of potassium bromid for six months without benefit and I hope without injury. He was cured by three bottles of some kind of patent worm medicine, taken at the suggestion of a neighbor and very much against my advice. This child had no worms, but he did have a distended abdomen, constipated bowels, foul breath, a poor and irregular appetite. The worm medicine got rid of these conditions, and the epilepsy was cured.

A year or so after this somewhat unique postgraduate course in epilepsy, I saw a case very similar and, making use of the knowledge I had obtained in my previous humiliation, I prescribed the old-time worn remedy, pink root and senna, not because of its vermifuge qualities, but for its action on the intestinal tract, and much to my satisfaction, the child soon recovered from the epilepsy.

Since then I have had a number of cases of this kind, and the result of this treatment has, with one or two exceptions, been very gratifying. Do not misunderstand me and think I believe that these drugs are a cure for epilepsy, for I do not think so, but they have a favorable action on the digestive tract, toning it up and removing irritation caused by partially digested food and foul and poisonous gases, and this relieves the cortical cells of a source of annoyance.

In treating epilepsy we can not be too careful in the examinations of our patients and especially regarding their habits, history and peculiarity of their attacks and any relationship that may exist between their habits and attacks. The necessity of all this knowledge was once demonstrated to me by a young man who had acquired epilepsy about a year before I saw him. He had been treated with immense doses of bromid by various physicians, and I simply continued the bromids in the form of the strontium salt, which he had not had before. This did not benefit him, and he seemed to take special delight in returning week after week to tell me it was doing him no good. Each visit added a little to my knowledge of the case. I finally realized that there was a relationship between his meals and the epileptic attacks, which generally followed breakfast and dinner, but seldom came on after supper. I also found that he went to bed early, and that it was usually two or three hours after breakfast or dinner that he had the convulsions. When these things became clear to me, I stopped the bromids, advised staying in bed all the time and modified the diet. In a short time the convulsions ceased. After two months in bed he was allowed to get up and nine months later was still free from the epilepsy. We will occasionally meet these cases that surprise us by getting well, and just why we can not explain.

A year ago I saw a little girl, 11 years of age, who had always been well and strong in every way till about one year before I saw her, when she suddenly began having convulsions; not getting relief from their family physician, she fell into the hands of various quacks, who treated her for several months, then she was taken to a surgeon. By that time her convulsions were becoming so frequent that she was having them about once an hour. The skull was trephined over the left motor tract and the brain was freely explored with a long needle, nothing abnormal being discovered; the child remained in a stupor for some days after the operation, and when this passed off she was free from convulsions, but idiotic, had lost nearly all muscular power, and was unable to swallow. She was in this pitiable condition when I saw her two months after the operation. She was then put on syrup of hypophosphites, cod liver oil, internally and externally, milk, cream and meat broths. It was hard work to feed her, but it was done, although it took time and patience. Much to my surprise, in less than two months she was able to sit up and to walk some, and is now to all appearances perfectly well, both mentally and physically.

The cases that I have thus far been touching on are principally cases of epilepsy in which the habit has not become fixed. They were in the state of development and were checked by the various means employed, but we all know too well that it is only a comparative few of these cases that yield to our treatment, and the question is ever present, what we shall do for the remaining ones, those who are condemned to be victims of this terrible sickness. Even among these people there remains a large and fertile field for us to cultivate, and we are not justified in saying at any time because the case is incurable by our present methods, that nothing can be done. Much can be done to benefit these unfortunates; even if they can not be cured, they can be materially helped, and now comes the important point, how shall we treat them and what shall we do for them? I must again repeat myself, and say that we should make a most careful study of our patients and continue this study till we are perfectly familiar with them in every way, if such a thing is possible, knowing how they eat and sleep, all their peculiarities, and especially about their organs of excretion. After we know all these things and many more, we then can begin to treat them rationally and with some hope of benefit, if we treat the patient and not the epilepsy. This treatment should aim at one thing in particular—to do everything to increase the vigor and health of the entire system, and in this connection trying to increase the vigor of the cortical cells, that the whole system may be brought to the highest point of perfection; the assimilation and elimination must be as nearly perfect as possible, food must be carefully selected. Each case is a study of itself; no regular line of diet can be laid down for all these people. What suits one may be a damage to another; the organs of elimination must be carefully observed; every effort possible should be made to prevent auto-intoxication. If this could be perfectly accomplished, I believe incurable epilepsy would be a thing of the past, but as we can not with our present knowledge accomplish this, we must do the best we can, and see that the organs of elimination that we are familiar with do their work properly. The bowels often are hard to handle, cathartics, enemas, diet, massage, all failing to keep them active. I have seen the kidneys go for even 48 hours without secreting urine just before an epileptic seizure. If we are helpless to prevent these conditions, we can not hope to control the epilepsy while the system is poisoned by retained fecal and urinary matter.

Much can be done by regular habits and exercise, baths, massage and fresh air; but I have found nothing so valuable as the high frequency current and the vibrator. The high frequency current seems to have a tonic effect that I have never seen from any other form of electricity, nor from anything. While it strengthens the general nervous system, it does so without exciting it; in fact, it often quiets it better than bromids or any of the sudorifics. It will frequently check that terrible restless nervousness that so often precedes an epileptic cycle, and will cause the patient to quiet down and go to sleep, thus aborting the attack entirely, or if not, relieving the general severity of the convulsions. It assists in the elimination and strengthens the muscles and nerves, thus relieving the constipation and indigestion, and keeps the kidneys and other glands up to their work. My experience with this treatment, not only in epilepsy but in other diseases, makes me believe that in it we have a most valuable and rational treatment, for many of the conditions of the epileptic, especially in children, where we can hope that natural development, thus encouraged and assisted, may materially improve the defective system.

It might be well here to notice the bromid treatment of epilepsy. The majority of authorities on this subject speak of it as the sheet anchor of our treatment and advise the increasing of the dose until desired results are obtained, and then a long continuation of the treatment. I am sorry to say that this advice has been followed almost literally by a great many who paid but little attention to any exceptions or any other directions that may be given. I have seen what I believe to be very disastrous results from this promiscuous prescribing of bromids, especially in young children. They have degenerated both mentally and physically so rapidly that it was impossible to attribute it to any thing but the large doses of this drug. While I can see how we may get good results in adults, and even in some children from them, I have yet to see any case of epilepsy that has been permanently benefited by this treatment. I have seen many cases where the attacks were diminished and even interrupted for a considerable period, but they have always returned and the patient has been in a worse condition than at first. I am not prepared to say, neither do I think, that the whole bromid business is irrational and wrong; but I do think that in a large proportion of cases it is used irrationally and without much consideration of the manner in which it acts. If we can by the use of these salts numb or stupefy the cortical cells for a time so as to get them to forget the convulsive habit and at the same time, by other means, remove from the system the cause of their irritation, we may do some good with the bromids; or if we can, while controlling the convulsions with them, carry on a line of treatment that will strengthen the general system and increase the resistance of the cortical cells, we may be justified in using them; or if we can establish the fact that they not only inhibit the cortical cell, but at the same time destroy some substance in the system that irritates these cells, then we could feel that they should be used in the liberal and careless manner in which they now so often are. My own experience would hardly uphold this last supposition; with my present ideas, if I were to administer bromids at all it would be only for a short time or while carefully observing the general condition of the patient, and stop them as soon as I saw signs of injury. Too often we are unable to see any indication of harm till serious damage has been done; for these reasons I do not like to give them in chronic cases, although the temptation to do so is often great. It is doubtful if any other drug gives us better results, for although many of those recommended for controlling the convulsions will do so for a time, the system seems to become accustomed to them and they lose their beneficial effect, and it is questionable if we have gained much by their use.

# RELATIONSHIP OF EPILEPSY TO CHRONIC GASTRO-INTESTINAL DISEASE.*

G. W. McCASKEY, M.D.
FORT WAYNE, IND.

While the pathology of epilepsy is, as yet, an unwritten chapter, there are several inferences which appear to me fairly well grounded. One of these is the existence of an organic defect in the finer and as yet inscrutable ultimate structure of the corticospinal neurons. Concerning the nature of this defect we are quite as much in the dark, but not any more so than we are with reference to the cognate defect which underlies hysteria. The assumption in both cases of such a fundamental deviation from the average normal type of construction of the nervous system, of the existence of inherent tendencies which are exceptional rather than typical, and which are possibly always inherited, or at least acquired during the early developmental period, appears to me absolutely necessary to explain why apparently identical causes will produce the clinical manifestations of these neuroses in one case and fail to do so in a hundred others. Whatever may be the real character of this change or deviation from the normal type, it is permanent and must be organic in nature. It bestows on the individual the liability to have epilepsy. He has, so to speak, potential epilepsy. Whether he ever has the manifest symptoms or not will depend on a variety of circumstances. Perhaps in one group of cases the psychical, sensory or motor instability, incident to this underlying organic basis, may be sufficiently strong to give rise to an evolution of the active disease, spontaneous in character. This, however, may well be doubted. The spontaneity is probably only apparent. Intrinsic or environmental conditions may easily furnish unrecognizable though efficient causes. In other cases the so-called exciting cause is sufficiently obvious—a traumatism, an emotional shock, an acute illness, a failure of elimination, etc. These are, however, the common incidents of life and are only efficient exciting causes of epilepsy in the presence of something entirely exceptional in the individual, namely, the organic basis already assumed.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

It is perhaps idle, in the existing state of our knowledge, to speculate on the nature of these variations from the usual or normal type of the nervous system. In using the term organic to designate them, it is not intended, of course, to convey the idea that they are demonstrable by our present means of research. The term, owing to its traditional associations, is even objectionable, but I have made a requisition on my vocabulary in vain for a substitute which would be at all adequate. In some sense these conditions which form the underlying permanent basis of such states as epilepsy and hysteria must be anatomic in their nature. That we are unable to determine their nature, or even demonstrate their existence, is simply a question of the limitations of our knowledge at the present time, or possibly for all time to come. A proper conception of this anatomic basis, however, should not have to wait on its histologic demonstration. Our general knowledge of pathology and the relation of structure to function would seem to point with sufficient logical force to the anatomic character of this underlying condition. A proper view of these conditions is important, if for no other reason than to throw a little restraint on harmfully aggressive and irrationally meddlesome therapeutics.

The other most important factor is that of irritation or excitation already referred to, and which may be of the most diverse character. It is with special reference to one of these groups of this causal condition, viz., those connected with the digestive organs, that this paper has been written. The cases of epilepsy, the study of which forms the basis of this paper, have been made the objects of more or less critical study with reference to digestion, metabolism, etc., and in many instances the relationship of the epileptic phenomena to these various disturbances has been shown to be of the closest character; so close, in fact, as to appear to fully justify the appellation of not only an efficient but an essential exciting cause. On the other hand, I am bound to say that in still other cases, at least superficially indistinguishable in type, no substantial results have been obtained. There must, of course, be radical and essential differences in these two groups of cases. It would seem to lie in one or both of two directions—either a difference in the grade or severity of the assumed organic or anatomic basis, which constitutes the potential epileptic state, or in the co-existence of other recurrent exciting causes, concerning the nature and identity of which we remain entirely ignorant.

There is, however, still another group of cases in which the efficacy of a removal of these exciting causes can not be adequately tested because of their remarkable intractability to treatment. Some of these cases are probably explained by lack of control with reference to diet, hygiene, etc.; but after making due allowance there remains a small group of such cases in which I have been forced to the conclusion that there is in some way a reversal of the relationship above indicated. In other words, the intractable nature of the disease of the digestive organs is in part at least due to perverted innervation. Whether or not there is an instability of the neural mechanism which presides over the musculature and secreting functions of the digestive organs, I am unable to say. The existence of such an influence would not be at all incredible. We know that the psychosensorial areas of the brain are involved as well as the motor, and the sympathetic, which is really subordinate to the cerebrospinal axis, or rather a subordinate part of it, may easily be implicated. Moreover, both the stomach and the intestines are in part supplied directly from the cerebrospinal system by the vagus. I do not now have reference to anything in the nature of a convulsive phenomenon, although this question might well be raised. I refer rather to a disturbance of what might be called the tonus of the neuromuscular mechanism of the digestive apparatus during the interparoxysmal periods. It finds its analogue in the weakening of the inhibitory control of the psychomotorial functions during the same period. If this condition can be assumed in the digestive tract, it furnishes a ready explanation of the clinical facts just cited. Motility is quite as essential to normal digestive function as digestive fluids, and if food stasis occurs, there exists a perfectly obvious source of toxemia, from gastrointestinal absorption. In addition, however, to the results of impaired motility, we should consider morbid variations in the character of the digestive fluid from the same causes. We have more direct evidence of such phenomena in neurotic patients than we have of such disturbances of motility as those above referred to. In the stomach, the secretions of which are most easily studied, we know that such patients show remarkable variations in the character of secretions, e. g., hyperchlorhydria at one time, and possibly achlorhydria at another. It is perfectly certain that such variations can not be due to structural alterations in the oxyntic glands. Their explanation must be assigned to the nervous mechanism of secretion; and it is more than probable that many of the bizarre gastric phenomena so often seen in epileptics, at least in my own experience, has a similar origin. The disturbances of motility and secretion which are so easily demonstrable, and so frequently observed in the stomach have, it is fair to assume, their analogies in the functions of the liver, especially its influence on metabolism, intestinal toxins and intestinal absorption.

I am firmly convinced from my own experience with these cases that in dealing with their digestive disorders, we must consider them in relation to the underlying defect of the nervous system, which has a distinctly sinister influence, and has at times been what seemed to me the one insurmountable obstacle standing in the way of at least some amelioration of the case. The following is a brief outline of such a case:

Mrs. K., aged 27. Referred to me March 27, 1899. The epileptic seizures had been recurring for about nine years every three or four weeks. Prior to that her health had been considered good, although she had evidently always been a marked neurotic, with somewhat belated development. Menstruation began past 15, and had always been scant, and her powers of endurance, mentally and physically, had never been good.

The epileptic seizure consisted first of a spasm of the muscles of deglutition, followed by general tonic and then clonic convulsions, with perfectly clear consciousness, and finally unconsciousness, passing into a deep sleep lasting three or four hours. Following this she would be decidedly ill from general nervous disturbance for three or four days when she would regain her ordinary type of health, which was really very far from good. There was, among other things, a history of gastro-intestinal disturbance, the symptoms comprising distress after eating, eructation of gas, constipation, and especially just before the epileptic period developed enormous gaseous distention of the entire abdomen, so extensive as to be the source of great distress.

Examination revealed chronic gastritis and colitis, and the patient was placed on suitable treatment with the expectation of decided benefit. I have every reason to believe that in the matter of diet and hygiene the patient's co-operation was intelligent and complete, and the treatment was the best that I could give her from every point of view, local and general. The character of the local morbid processes was such as would ordinarily yield to the line of treatment instituted, but in this case proved utterly rebellious. There was no substantial improvement in either the gastro-intestinal disease or the epilepsy during the time that the patient was under observation—which was perhaps two or three months. The putrefactive processes of the intestinal tract seemed entirely beyond control by either diet or medication combined with suitable local treatment, and the patient finally passed from observation unimproved.

Another case of an entirely different character was that of a boy about 15 years of age whom I first saw 5 years ago. There was a history of irregular nocturnal attacks of grand mal closely associated with exacerbations of a chronic stomach disease. In this case an apparent cure of epilepsy followed a comparatively brief course of treatment. I heard from the patient at intervals through his physician, and he remained well for over three years. Owing to the death of the physician, who lived some distance away in an adjacent city, I lost track of the case. My record might have shown permanent cure, and three years would apparently have justified the record had the patient not been brought to my office within the last year by another physician with a recurrence of the epilepsy after about four years of complete freedom from attacks. Apparently other causes were operative, as nothing more than marked improvement has been secured, although bromids were given during the last course of treatment, but not during the first.

Many cases could be recited showing varying degrees of improvement for varying lengths of time, clearly as the result of suitable treatment of the digestive diseases without bromid or other sedative medication. It will scarcely be proper to discuss in detail the local and general measures directed toward the gastrointestinal diseases. This belongs to another section, at least so far as the severer types of disease are concerned. The importance of giving proper attention to the digestive organs in general is fully recognized by every physician, but is emphasized by facts such as I have presented. It would appear desirable, however, to give more attention to an exact diagnosis of the morbid states of the gastrointestinal tract. Unless the physician is prepared to carry out the technical methods of diagnosis, as well as of treatment where this is indicated, the services of the specialist should be invoked for this purpose, if it is desired to do all that can be done for this group of cases.

I think there is no doubt that this line of treatment is of great value in cases of epilepsy associated with either obvious or latent gastrointestinal disease; and it should be remembered that there are many cases without obvious symptoms. I have not infrequently found large amounts of semi fluid débris in the fasting stomach where all stomach symptoms were denied. This forms, both in those which are latent and in those with manifest symptoms, an excellent culture medium, and is usually, in fact, a rank growth of a mixed infection. Bacterial toxins are necessarily formed in large quantities and absorbed in the circulation. The infected culture fluid also passes on into the intestines and intensifies the infection there. We must also consider the local irritative effect of these morbid constituents on the terminal vagosympathetic filaments of the gastric mucosa. Such reflex phenomena may well be disturbing factors in cases with marked instability of the nervous system.

There are doubtless other ways in which disturbance of the digestive tract may directly or indirectly exert an unfavorable influence on the frequence and severity of epileptic attacks. Enough has been said, however, to indicate the relationship of these disturbances to epilepsy, and I will not occupy more time in its discussion.

---

# ECHINOCOCCUS CYST OF THE LIVER,

## WITH REPORT OF A CASE WITH OPERATION AND RECOVERY.

BAYARD HOLMES, M.D.
CHICAGO.

There are two forms of hydatid cyst which show themselves in the human liver. The more common one is the *Echinococcus cysticus;* the rare one is the *Echinococcus alveolaris.* The life history of the *Echinococcus cysticus* has been very fully studied by Leuckart, and further studies may be consulted in Bulletin 19 of the Bureau of Animal Industries of the United States Department of Agriculture, published in 1898.

### LIFE HISTORY OF THE PARASITE.

The position of the echinococcus cyst in the life history of the animal is extremely interesting. A tapeworm (Fig. 1) only 1.5 to 3.0 mm. long, which infests the intestinal tract of the dog and other canidæ, deposits its eggs by millions with the excreta. By natural processes the eggs are washed out of the excreta and fall on vegetation, which sooner or later becomes the food of man or other intermediary host, mostly the herbivora. In the intestinal tract of the host a few of the eggs are so acted on by the contents of the stomach or intestines that the shell falls off and the embryos gain access to the circulating juices of the body. Either actively or passively they are carried through the portal circulation and reach the finer capillaries of the liver. Here they develop into enormous cysts, which by a complex system of budding (Fig 2) become multiple embryos. On account of the presence of the cysts, the intermediary host suffers in health and strength, and is, therefore, more easily overcome and devoured by the primary host, the dog or other canidæ. The dog consumes the infected liver; the embryos are set free and attach themselves to the lining membrane of the intestine by the hooklets with which they are provided. Here they become messmates and perhaps parasites of the dog, and complete the circle of their existence by a bisexual development and the discharge of millions of eggs in the excreta.

### GEOGRAPHICAL DISTRIBUTION.

The geographical distribution of echinococcus is extremely interesting. It is a common affection of dogs and men in Iceland, some parts of Australia, and in the Provinces of Mecklenburg and Pomerania. In the neighborhood of Greifswald 68 per cent. of the cattle, 51 per cent. of the sheep, and 5 per cent. of the hogs are, according to Piper, afflicted with the echinococcus disease. In France, England, and other European countries; in Algiers and Egypt, the echinococcus is occasionally observed (Fig 3). In America only one infected dog has ever been found. Some few imported cases have been recognized in men, and a few so-called sporadic cases. In northern Michigan, Minnesota, the large cities, and in the Province of Manitoba, the disease has been recognized in immigrants from Iceland, Mecklenburg and other European countries. Fifty-nine cases have been reported from New York, 56 from Manitoba, 24 from Pennsylvania, 13 from Maine, 9 from Ohio, something like 250 in all.

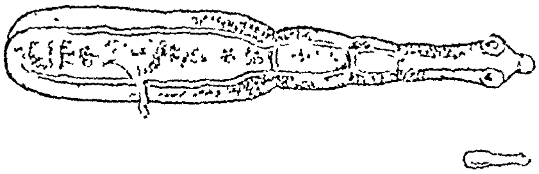

Fig. 1.—The tapeworm of the dog, one-half natural size and magnified.

### CLINICAL HISTORY.

More than half of all echinococcus cysts are found in the liver. They are usually single, and more often appear in women than in men. They usually occur between the ages of 20 and 40, though children and those of advanced years occasionally suffer. In the liver the cysts are more often in the right lobe than elsewhere. The form of the liver is changed to correspond with the location of the cyst, with its size, and the rapidity of its growth. The position of the cyst may sometimes be recognized by the bulging of the liver, either toward the diaphragm, downward into the abdomen, or in some other direction. Rarely the cyst may obstruct the biliary passages, and thus produce jaundice or partial jaundice; sometimes it produces pressure on the vena cava, sometimes on the portal vein and sometimes on the blood supply of the liver itself, producing gangrene.

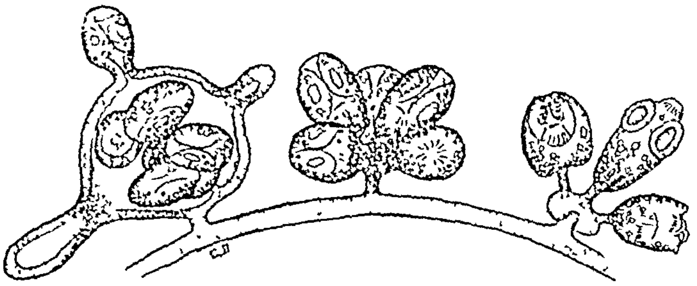

Fig. 2.—Different methods of budding (from Leuckart).

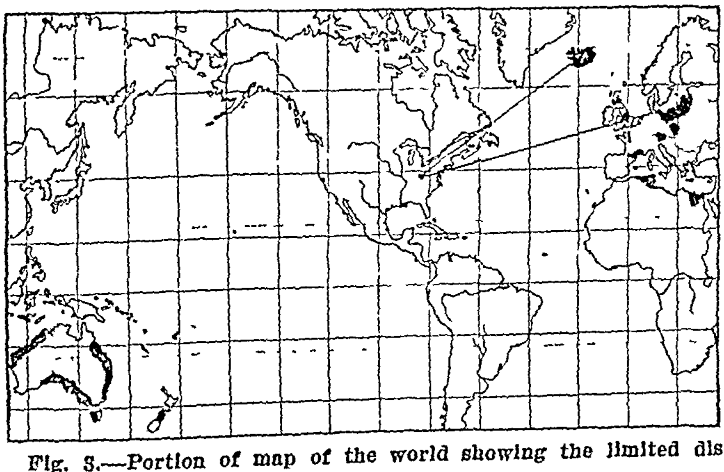

Fig. 3.—Portion of map of the world showing the limited distribution of *E. cysticus*.

As a result of pressure atrophy, the cyst advances in one direction or another, and occasionally opens into the general peritoneal cavity, or some viscus, into the pleural cavity, into the pericardium, and even into the pelvis of the kidney. Rarest of all, it breaks through the skin of the abdominal wall.

Traumatism may result in early rupture of the cyst, and this again in death. At other times the same accident may bring about the recovery of the patient and the cure of the disease.

Suppuration sometimes takes place in the cyst and produces abscess of the liver. The cyst frequently dies, and its contents, being sterile, undergo the ordinary changes which are to be found under like conditions in cysts of other origin. There are no complications which occur in abscess of the liver which may not occur in echinococcus cyst.

### SYMPTOMS AND DIAGNOSIS.

The symptoms of hydatid cyst of the liver are so indistinct that the tumor is frequently the first suggestion of the disease. Cysts as large as the fist are often latent and unsuspected. There are no abnormalities which can be recognized in the urine. The absorption of toxic elements occasionally gives rise to urticaria and digestive disorders, especially to a repulsion for meat and fatty foods. This is sometimes so severe as to produce vomiting or diarrhea. Psychoses of various forms often show themselves in the course of echinococcus disease, but the only one which is frequent enough to be of diagnostic significance is the urticaria. The gastric disorders may be either psychic in their origin, or they may be due to interference with the biliary secretion, or to the movement of food in the duodenum by pressure.

The patient usually complains of fulness and heaviness and sometimes of pain and pressure in the region of the liver. Jaundice occasionally shows itself in the mild form, and the stools are interruptedly clay-colored and stained with bile. The liver, as a whole, is somewhat enlarged, and the location of the tumor may give an irregularity suggestive of abscess or carcinoma. The hydatid thrill which has long been recognized is not often observed even in the presence of large hydatid tumors, and it is sometimes present when the tumor is located in the omentum, mesentery or pancreas. Abscess of the liver also occasionally presents the thrill. This test is made by laying the left hand over the tumor and lightly tapping the opposite side of the tumor with the fingers of the right hand, the fingers being retained quietly in position for a few minutes after the tap is made. A peculiar vibration is felt somewhat resembling the vibration of a violin under a very low tone. The examination of the blood is not significant. There is a mild anemia, which progresses with the continuance of the disease and is increased by interference with the biliary or digestive function. Only a small proportion of cases of hydatid are diagnosed before the autopsy.

### NARRATION OF A CASE.

In my own practice I have seen three hydatids. Two were on the postmortem table at Cook County Hospital; one in an Icelander, and one in a German of unknown nativity. Both were hydatids of the liver and both were unrecognized before death. The third case is one in which the diagnosis is perhaps a little obscure. The conditions found at the operation would indicate that the hydatid was dead and sterile, and was undergoing a degenerative change. The history of the case was carefully written before the operation, and is of sufficient interest to be reproduced:

*Painful affection of the hips, extending over two years, in an American girl of German parentage; appearance of a tumor or enlargement of the liver; under observation for four months; exploratory laparotomy; removal of a dead cyst and evacuation of a large sterile cyst; recovery.*

*Previous History.*—Nov. 28, 1902, Miss D., 20 years old, born and reared in northern Illinois, was placed in my charge by Dr. Robert H. Babcock. She gave the following history: When a child she was very ill a number of times with the croup, and she also believes that she had measles; her girlhood was generally healthy, and she was of vigorous bodily habit. Twice she has had a condition which was diagnosed la grippe; once in 1893, and again in February, 1902. This last time she was very sick for about ten days. During this attack an eruption appeared on her shoulders, hips and knees, which faded out during early convalescence (urticaria?). She has suffered acute tonsillitis once, and last winter she had a so-called facial eczema which ran a course of about five weeks (urticaria?). Three years ago and without apparent cause, she suffered from nervous prostration. A few years ago, when run down in health, she had a few fainting spells that lasted only a few minutes each, and she insists that she was not hysterical at the time. She suffered for several years with headaches, which disappeared on wearing suitable glasses. She has never at any time had chills or fever. At thirteen she began to menstruate, but this function has not always been regular, and when irregular has been too early. For the last year menstruation has been regular. In October she menstruated a week late, and after that time she did not menstruate until the first week of March following her operation. Her menstruation is normal, with no great amount of hemorrhage, no pain or psychic disturbance, and she does not go to bed.

*Family History.*—Her family history is splendid. Her parents were German born; her father died from an overdose of morphin; her mother, 56 years old, is in good health. She has three perfectly developed brothers, and there have been no deaths among the children in the family. No close or distant relatives have died from tuberculosis or cancer.

When a child she played with a little girl suffering from a suppurating middle ear, but she does not remember having lived in the house or associated with any one who had consumption or a running sore. She never played with a dog or had a pet except once when a girl. It was a white, shaggy poodle, and she had it for not more than a year or a year and a half. The house in which she has lived most of her life is isolated and not overhung by trees. Her room was on the second floor, with two south and one west windows. The water supply of the house was a well of very hard water. While away at school she was in a pleasant room, abundantly lighted and supplied with water from a well. The school was situated on high and well-drained land.

*History of the Disease.*—Four or five years ago, about 1898, she began to have pain in the left hip; this pain did not make her limp. She consulted Dr. John C. David, Sandwich, Ill., who treated her for a year and then took her to Dr. George F. Shears, Chicago, who considered the trouble due to some disturbance in the pelvic circulation. In the spring of 1900 she made a tour of several months in Europe. She stopped at Bremen, Einbeck, Hanover, Frankfort, Strassburg, Lindau and Berlin. While in Germany she often walked three or four miles a day, but had no pain in her hip. She sometimes had pains radiating from the knee to the ankle and up around her back. She returned from Europe in the fall of 1900 feeling quite well, and had no further trouble until the spring of 1901, when the pain in her hip returned very suddenly one afternoon. Rubbing the hip and leg with alcohol seemed to relieve her suffering, but in two or three weeks the pain had extended into the knee and ankle and had become so contant and severe that she called Dr. L. L. Culver, Sandwich, who put her in the care of Dr. A. J. Ochsner early in September. Dr. Ochsner diagnosed tuberculosis of the left hip, and put her to bed at the Augustana Hospital with extension on the left leg. At the end of a week she began to suffer severe pain in her right hip, and extension was placed on this leg also. She remained in the Augustana Hospital for four weeks with extension on both legs. She was then removed to her home and the extension was continued six weeks longer. The extension was then removed from both legs and she was kept in bed for a month. After some preliminary treatment a splint was applied to the left leg and she began to walk with crutches. The extension and the rest in bed had relieved the pain in the hips, and when she began to walk she complained of nothing except weakness in both hips.

In February, 1902, she had an attack of la grippe, with urticaria and a slow convalescence, after which she abandoned her crutches and began to walk with a cane. In July, 1902, she again had pain in the left hip, which was greatly relieved by rubbing the leg with alcohol. On admission to the hospital she had occasional slight pains around the left hip, which she said were not deep. She had had no pain in the right hip since the extension was taken off. She walked gracefully and without limping.

About the middle of September, 1902, she returned to her school at Naperville, Ill. She felt quite well and gained ten pounds in weight during the five or six weeks she was there. Late in October, however, she noticed a swelling on the right side of the abdomen above the umbilicus, which seemed to her to increase slowly and regularly in size and outline. While taking deep-breathing exercises she noticed considerable pain in the region of the liver. For two or three months previously she remembers that she had difficulty in digesting potatoes and other vegetables, and was constantly distressed after eating by the fermentation of her food and the formation of gas in her stomach. The very sight of meat and potatoes, white bread and ordinary articles of diet, disgusted her, but she enjoyed thin soups, fruit, candy and ice cream. She was inclined to be constipated, but after she had eaten and had eructated gas from her stomach her bowels would move very loose and watery. For a few days in October she remembers that her feet were swollen early in the morning. During the months of October and November she had pain over the region of the gall bladder and liver and in the muscles of the back. This pain radiated to a spot in the neighborhood of the fourth right rib behind, sometimes rising into the shoulder and extending to the left shoulder when lying down. Late in October, 1902, she consulted Dr. Culver, Sandwich, who made out a great enlargement of the liver, but she nevertheless returned to school. After this she became slightly jaundiced and was greatly depressed in spirit. November 24 she consulted Dr. Robert H. Babcock, who placed her in my care.

*Examination.*—The patient is found to be a young woman of perfect and beautiful development, with dark brown hair and dark gray eyes. Her skin and conjunctivæ are of a yellowish color, which is especially noticeable in the morning. She is five feet five inches tall, and weighs 120 pounds. She is well nourished; the skin is moist, and there is a slight edema of the lower extremities. The cubital and axillary lymph glands are not recognizable, but there are a few palpable lymph glands in the neck. The examination of the eyes, nose, mouth and ears reveals no abnormalities. The right lung extends downward to the upper border of the fourth rib in the mammary line, the fifth rib in the axillary line, and the seventh rib behind. The left lung extends to the lower border of the third rib to the left of the sternum, the sixth rib in the axillary line, and the ninth rib behind. Over this area the respiratory and vocal sounds are normal, and there are no evidences of consolidation, effusion or disease.

Cardiac dulness begins in the fourth interspace about three-quarters of an inch to the left of the mammary line; there is no cardiac dulness to the right of the sternum. It extends to the lower border of the second rib on the left of the sternum, to the upper border of the third rib in the mammary line. The apex beat is in the fourth interspace just external to the nipple; both tones are loud and distinct. Over the base of the heart the second tone is markedly accentuated.

The area of relative dulness of the liver begins in the third interspace in the mammary line, and absolute flatness begins at the lower border of the fourth rib in the mammary line, at the lower border of the fifth rib in the axillary line, and the lower border of the seventh rib behind. The edge of the liver is palpable below the costal arch and extends as low on the right side in the mammary line as the level of the umbilicus. It is just above the umbilicus in the median line, and extends across the abdomen to the level of the tenth costal cartilage. The anterior surface of the liver is smooth and uniform, dense and unyielding to pressure, and without fluctuation or any marked irregularity. The edge is distinct and round, and the notch of the liver is distinctly palpable. At a subsequent examination a few days later a distinct, irregular tumor was recognized and the accompanying sketches were made to represent it. (*Figs. 4 and 5.*)

The gall bladder, unless the tumor above is the gall bladder, is not palpable. The left lobe of the liver extends as far as the left axillary line and as high as the sixth rib; it seems to completely fill the left hypochondriac region. The spleen is not palpable as a separate mass to the left of the liver. No fremitus or thrill can be felt on palpation anywhere over the surface of the liver, nor can any friction sound be detected on auscultation. There is a marked bulging above the umbilicus and a little to the left of the middle line. There is no tenderness over the liver on moderate pressure; no enlargement of the veins of the abdomen or groin; no enlarged lymph glands about the umbilicus. The abdomen measures 31 inches at the ensiform cartilage; 30½ inches at the umbilicus, and midway between these points, over the most prominent protrusion of the tumor, 30¼ inches. The distance from the ensiform cartilage to the umbilicus is eight inches.

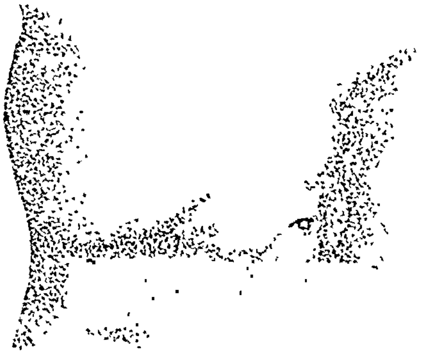

Fig. 4.—Showing outline of tumor on the right side of abdomen as sketched before operation.

The area of stomach resonance extended downward to the level of the umbilicus, and toward the left to the border of the tenth rib, about two inches lower than the palpable edge of the left lobe of the liver. The stomach contents were not examined. The right kidney was not palpable, and only at times could a suggestion of the lower pole of the left kidney be made out. There was no tenderness over the appendix or any other part of the abdomen.

The examination of the pelvis revealed a perfectly normal virgin sexual apparatus, and cystoscopy showed a perfectly normal bladder. The veins of the legs were not enlarged; there were no hemorrhoids; the nails on the fingers and toes were unmarked by ridges, the evidence of malnutrition, and were perfectly smooth and pink. There was no disease of the skin or hair anywhere on the body.

When the patient entered the hospital November 26 her temperature was 98, at 10 o'clock in the morning, her pulse 100 and her respirations 24. An examination of a specimen of urine gave an acid reaction, a cloudy appearance, a straw color, a specific gravity of 1010, with no albumin, sugar or casts, and only a few squamous epithelial cells, a few leucocytes and an abundant deposit of crystals of oxalate of calcium. During the following week her temperature varied between 97.5 and 99.5, with no noticeable character in its fluctuation. The pulse was regular, even and varied between 72 and 88. Her respirations when recorded were in the neighborhood of 20.

A number of complete urinary analyses were made, but they revealed nothing significant. November 30 she passed 1,000 c.c. of urine in 24 hours, of a specific gravity of 1006, an acid reaction, a trace of albumin present, but no casts; total solids were 13.2 gm., and the urea 7 gm. in 24 hours. December 3 another specimen of urine was examined. It showed an acid reaction, but only .3 per cent. of urea. On this day the ureters were catheterized. The left ureter gave 7½ c.c. of urine in 30 minutes, which would amount to 360 c.c. in 24 hours, making the total quantity for the two ureters 720 c.c. The urine from the left ureter was acid; it contained .3 per cent. of urea, no casts, no epithelial cells or abnormal microscopic findings. Following this catheterization she passed 9 c.c. of urine from the bladder at 2:30 p. m. This urine is presumed to have come from the right ureter. The characteristics were the same as those above. At 3:30 p. m. she passed 25 c.c.; at 4:00 p. m. 50 c.c.; at 6:30 p. m. 90 c.c. Every specimen of urine passed after the catheterization was slightly bloody, and had a specific gravity of 1010.

The catheterization was made with the Lewis electric cystoscope, the bladder being distended with air. By some mistake the right catheter was passed into the left ureter, which made it impossible to go on with the operation and pass the left catheter into the right ureter. The cystoscope was therefore withdrawn, and as the demonstration of the competency of the kidneys was complete, no further effort was made at catheterization. The blood in the last specimens was doubtless from the slightly overdistended urethra.

Frequent examinations were made of the blood; on December 2 one count made by Dr. Adams showed 5,160,000 red corpuscles; 7,800 white corpuscles, and a Fleischl hemoglobin percentage of 75. This was almost identical with the first count of November 29. December 22 the red corpuscles and the hemoglobin remained the same, but the leucocytes numbered 12,000 to the cmm.

The enormous enlargement of the liver and the findings which are reported above were inconsistent with any probable diagnostic hypothesis which occurred to me. The afebrile course, the low leucocytosis, the lack of prostration or toxemia, spoke strongly against abscess of any kind, except possibly tuberculous abscess or abscess due to the typhoid bacillus. Any abscess which would give rise to so little disturbance must necessarily be very chronic, or else within a natural cavity of the body. The uniform enlargement of the liver would be unexplained by an empyema of the gall-bladder, neither would it be consistent with abscess of the liver itself, or even with the improbable echinococcus of the liver. The history of pain in the hips, giving rise to the erroneous diagnosis of hip-joint tuberculosis, might possibly indicate the origin of the tumor affecting the sacral nerve. These nerves probably arise from the second, third and fourth lumbar, and the second and third sacral nerves. The history of the case and the general appearance of the patient seemed to speak against the diagnosis of malignant disease, and there is nothing in the history which points strongly either to carcinoma or to sarcoma.

After writing out the above indication and feeling the uncertainty of the diagnosis, I thought it prudent to send the patient home and give her the advantage of a therauptic test for syphilis of the liver. She was accordingly put under the immediate care of Dr. Culver, Sandwich, and given an eighth of a grain of corrosive sublimate hypodermically every day for ten days, and twenty grains of the iodid of potassium in milk or beef tea three times a day. During her stay at home she maintained a temperature between 102 and 103 every evening except one, and this evening she was more miserable than at any other time. Her morning temperature was regularly subnormal.

On December 19 she returned to the hospital. The girth of the abdomen immediately over the tumor had diminished one and a half inches. The notch and irregular spot on the edge of the liver had increased to the size of the fist, and was excessively tender. December 21 she was again carefully examined by me and Dr. Bertram Sippy, but no new points were brought out by our study together. He recommended an exploratory operation, probably for a suppurative cholecystitis. The leucocytes now numbered 12,000; the temperature remained permanently above normal; the urinary secretions showed an excessive amount of coloring matter, probably bile pigment, and a little albumin and peptones.

*Operation.*—The patient received the usual preparation for a laparotomy, and on the morning of December 22, with the assistance of my associates, Drs. Frank Blatchford, Edward T. Alford and Will H. Moore, I made the operation. The anesthetic was nitrous oxid gas, followed by chloroform, and afterward, at 11:30, by ether, and was administered by Dr. D. H. Galloway. After the preparation of the skin of the abdomen, the abdominal wall was opened and the tumor discovered at 11:15. The protrusion which had been felt in the neighborhood of the umbilicus was found to be a hard, white, superficial tumor in the border of the liver near the fissure. Behind this tumor there was a large fluctuating tumor in the right lobe of the liver and an inch and a half or two inches from the smaller tumor. An incision was made in the larger tumor, and a clear, yellowish-green fluid poured out. The cyst seemed to hold about a quart of fluid. The finger was passed into the incision, and by means of several mattress sutures, passing from the outside of the liver to the inside of the tumor, a triangular piece of liver substance, containing the smaller tumor, was ligated off with catgut, and a segment of liver, three and a half inches or more on each triangular side, was removed. There was very little hemorrhage from the surface of the liver; the interior of the cyst was carefully sponged out; the whole cyst cavity and the denuded surfaces of the liver were covered with an iodoform gauze tampon, which was brought out of the upper corner of the wound, and after exploring the gall bladder and common duct the pancreas and the pylorus, the remainder of the abdominal wound was closed. The skin suture was complete at 12:20, and the operation lasted an hour and five minutes after the first incision was made.

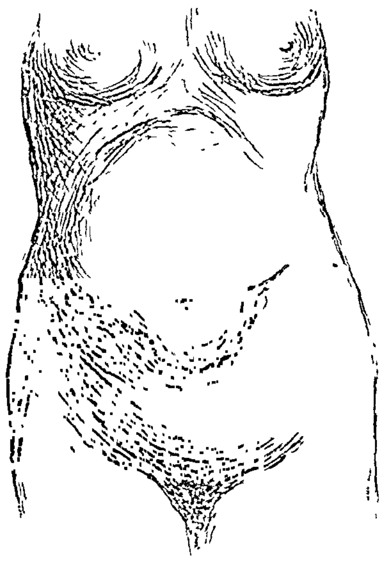

Fig. 5.—Sketch of abdomen showing the general configuration and outline of tumor.

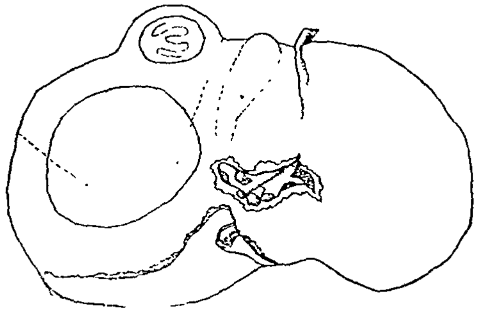

Fig. 6.—Diagram of section of liver showing lines of incision for removal of cysts.

Immediately after the operation the tumor was carefully examined, and the sketch (Fig. 6) of the relation of the tumor, the cyst and the gall bladder was made.

*Examination of the Cyst.*—The material removed from the cyst and the tumor were placed in the hands of Dr. H. Gideon Wells for examination, who made the following report: "The specific gravity of the fluid taken from the large cyst was not recorded. It was golden brown, slightly opaque and rich in bile pigment and albumin. It contained considerable detritus, a few red blood cells, a moderate amount of cholesterin crystals, but no echinococcus hooklets and no sugar.

"The wall of the large cyst when examined from within outward consisted of three layers. The first layer was old fibrous tissue, partially hyaline and partially degenerated, poor in nuclei, devoid of leucocytes, almost avascular and without a lining epithelium over its surface. The second layer consisted of a broad, richly vascular zone, consisting of a network of widely dilated capillaries with a few or no arterioles. The capillaries were separated by a homogeneous material, which for the most part was not nucleated. The character and distribution of the capillaries suggested that they were the original capillaries of the lobules of the liver. The intervening tissue had the disposition of liver cell cords. It is probable that either the liver cells themselves had undergone hyaline degeneration, or they had been substituted by connective tissue, which later suffered the same change. A few groups of well preserved liver cells and bile ducts occurred in this zone. The third layer consisted of a promiscuous mass of fibrous tissue, liver cells, bile ducts, and the vessels normal to the liver, but without lobular structure. Liver cells occurred in small groups and small cords. A good deal of young connective tissue, granulation tissue and bile ducts surrounded by concentric layers of connective tissue filled up the picture.

"The small cyst consisted of thick, lamellated and corrugated sheets of hyaline substance having the consistency of cartilage. Between the folds of these sheets was a white, amorphous, pulpy substance, which consisted principally of fat, calcium salts, cholesterin crystals and detritus. The cartilage-like substance did not give any albumin or sugar reaction. Microscopically the thick sheets appeared hyaline and lamellated. The capsule was thick, composed of adult fibrous tissue and surrounded by liver substance containing much increased amount of fibrous tissue. No hooklets were found in the cyst.

"In the liver tissue surrounding the cysts there was a great production of interlobular tissue, with much granulation tissue. The lobules were atrophied almost to one-half their normal extent. There was no pronounced growth of fibrous tissue within the limits of the lobules themselves. The bile ducts were surrounded by concentric layers of fibrous tissue. There was active congestion of the liver, with increase in the number of bile ducts, but no fatty degeneration or infiltration. The diagnosis was echinococcus cysts, with early surrounding cirrhosis of the liver."

*Postoperative History.*—After the patient was removed to her room she reacted promptly, and had the most trifling disturbance from the anesthetic and the most insignificant shock from the operation. Her temperature never rose above the most trifling reaction; she never had any albumin in the urine, and the quantity of urine rapidly increased. The bowels moved without disturbance, and the jaundice disappeared. The thick, loggy, old-aged look which she had before the operation, and the jaundice which was so evident in the scleræ and skin, quickly disappeared, and she took on a youthful rosy, healthy look, which caused everyone to exclaim. She had a moment's chloroform anesthesia when the deepest portion of the tampon was removed on the seventh day, but otherwise she was dressed without pain or discomfort, and the cavity closed and the wound healed in a remarkably short time. No urticaria followed the operation.

Since leaving the hospital on the last of January she has been active and in buoyant spirits. Her health and complexion were perfect in June, 1903, when last seen by me, and she has absolutely no evidence or hint of a return of the disease. She has menstruated regularly since the first week of March. In June, 1903, her waist measured 23½ inches and she weighed 122 pounds.

### TREATMENT: PROPHYLACTIC AND SURGICAL.

The treatment of echinococcus cyst is a matter of little immediate importance to the American physician. All association with dogs, however, especially with imported dogs, should be looked on as not unattended by dangers. The presence of dogs in and about truck farms and gardens, about grocery stores and kitchens must be looked on as dangerous and filthy. America can hardly hope or expect to remain free from the echinococcus for any great length of time, and when the disease is once discovered it should be promptly reported and the source of the disease should be sought for.

Medical treatment is absolutely useless. The only surgical treatment is laparotomy, the opening and the evacuation of the cyst, and probably tamponade and drainage; but these details are matters which must be left entirely to the surgeon. No exploratory puncture, no tapping and washing out of the cyst, can be looked on with complacency.

# THE PROPHYLAXIS OF PLAGUE.

J. J. KINYOUN, M.D., Ph.D.
GLENOLDEN, PA.

*(Concluded from page 147.)*

### MARITIME COMMERCE IN ITS RELATION TO THE SPREAD OF PLAGUE.

Plague, like cholera, follows in the wake of commerce. For a long time many features connected with the transmission of plague by vessels were not understood. While it was easy to discern the relation existing between a vessel having cases of plague on board and others contracted from these on land, we were often at a loss to discover the origin of outbreaks occurring at seaports which could not be ascribed to vessels or their personnel. The various theories in vogue from time to time were a natural sequence. The careful observations of the past few years have been of greatest value in determining just what part the vessel, cargo and personnel play in the transmission of plague. Is it possible for the personnel of a vessel to bring the infection aboard, either in their persons or in their effects? Only a few instances have been cited where the personal effects of the personnel have been responsible for plague appearing on shipboard. Ruffer believes that a few cases are traceable to this cause. The dirty, filthy rags of the Indian pilgrim coming from Bombay and Calcutta were thought to be responsible for the outbreaks on shipboard, yet these were few and could not be traced directly to these as the cause *per se*. Kitasato mentions a box of clothing of a soldier who died of plague in Formosa sent to Kobe, and soon after opening it plague attacked some of those who had handled these articles.

It would perhaps further our understanding of this feature if a few details were indulged in which relate to one of the chief sources of infection to this country. Vessels in Hong Kong harbor, as a rule, lie at anchor some distance from shore, communication being held by steam launches, the native sampan and cargo boat. Very few of the trans-Pacific vessels ever touch at a dock. Nearly all these carry a full complement of Chinese for their crews. These are shipped in Hong Kong for the round trip and are changed on each return voyage. Only a few of the crew come from Hong Kong, the greater proportion being drawn from Canton and its immediate vicinity. As soon as a vessel arrives in Hong Kong a crew is discharged, the members return to their homes, and if any of these reship they return only a day or so before the vessel sails. These, together with the new members, constitute a fresh crew.

Early in 1899 cases of plague began to appear in several of these vessels, usually from three to five days after leaving Hong Kong. These were apprehended at the Japanese quarantines. The short time elapsing between the time of departure and the appearance of the cases pointed strongly to the fact that these were either pestis minor or pestis major in the incubative stage, and presumably the latter, as all attacked died. The possibility of the infection being brought on shipboard in their personal effects can not altogether be excluded, yet the weight of evidence leans further to the side of the person being the factor, rather than the effects.

While serving as quarantine officer at the port of San Francisco I soon became convinced that there was great danger from this source, and in response to persistent and urgent appeals, the surgeon-general finally detailed officers of the Marine-Hospital Service for duty at Hong Kong to make the inspections and to exercise a sanitary surveillance over all vessels destined for the United States. Since this inspection has been established, the effects of the crew and steerage passengers being disinfected, no case of plague has occurred on any of these vessels. Many cases of incipient fever, etc., have been excluded, and some of these have died soon after with plague. This would seem to indicate that the cases which had heretofore occurred on these same vessels were in reality suffering from plague on departure.

The Canadian vessels, for purposes and reasons best known to the officers of that company, have adopted a policy of inspection only, claiming in so doing that the restrictions imposed by the United States were worse than useless; that their system of inspection without disinfection was far better or "just as good." It almost seemed so until a case of plague was detected on the vessel's arrival at Nagasaki. Possibly this case was due to infection from some article taken on board, but it is also more than probable that on account of the short time elapsing before the appearance of disease (4½ days) that the personal inspection was at fault—a case of plague in the incubative stage was allowed to go on board.

The sanitary history of these vessels is quite instructive. Seven vessels had plague on board en route from Hong Kong to San Francisco; in only two did secondary cases occur. In five vessels cases occurred soon after leaving Hong Kong; in one of the two about 10 days after leaving port, in the other over 14 days. From a careful inquiry it seems to establish the fact that these cases occurring as soon as four days from port were in the incubative stage, whereas those developing after 10 to 14 days contracted the infection through some agency on shipboard.

### CARGO.

Since the days of the Levantine Lazaretto, the cargoes of vessels have been regarded with suspicion, and a belief held that such were capable of transmitting contagion. Certain articles of cargo are no doubt the means of preserving and transmitting the contagion of certain diseases, and are also capable of being infected, particularly so on shipboard. It has never been accurately determined how plague reached Bombay from Hong Hong. All the evidence points to an infected vessel. Certainly if a vessel can come from Bombay to Yokohama with plague-infected rats on board, or a vessel from Bombay arriving at Kelung, Formosa, with a case of plague, we would reason that it would be equally possible for infection to reach Bombay from Hong Kong.

From all information obtained, the cargo is not believed to be the principal means of its dissemination of plague. The cargo in most instances is free of infection at the time of placing on board, yet it may be infectible by agencies on board. There is a suspicion that certain food products from China may, either through their mode of preparation or storage, become infected with the plague bacillus, but these instances are rare. Cargoes of grain, particularly rice and of forage, may become infected by the same agencies. It is more than a probability that the disease was carried to Oporto, South Africa, New Caledonia and Calcutta in such cargoes. Kitasato's researches also appear to establish the fact that infected cotton shipped from Bombay to Osaka was the means of introducing plague in the latter place.

We can not, however, rest the case on the cargo alone as being the means of conveying plague, and must not be unmindful of the close relationship existing between the rodent and plague on land. The same will also apply to vessels. While certain classes of food products and other kinds of cargo may be infected with plague, I think all will agree that it is of minor consideration as compared to the dangers arising from plague infected rats on shipboard. These may become infected either by persons or their effects, or from infected cargo. On the other hand, they may become the means of infecting cargo. The steamship *Friary* arrived at Hull, England, about 80 days out from Montevideo. Two cases of fatal illness occurred en route and soon after departure; all were well on arrival. A few days after cargo was broken and begun to be discharged by the crew, when soon thereafter two became ill with symptoms of influenza, and were sent to the hospital. One of these died shortly after. About this time several mummified rats were discovered among the cargo. This, taken together with several other cases, led to a more careful examination, which demonstrated the cases were not influenza, but plague. The inquiry further developed that all the cases of plague had come from direct contact with the dead rats.

Another steamer arrived at Hamburg from Rosario, Brazil, where plague was prevailing. All were well during the voyage and on arrival. The quarantine inspection revealed several dead and sick rats. These were examined and found infected with plague. Another instance was an infection of the personnel by rats in the case of the steamship *Coptic*, which sailed from San Francisco for Asiatic ports in August, 1900, and 21 days later, just before arriving at Yokohama, a case of plague developed in a passenger. On clearing out the compartment two dead plague rats were found. Another steamship plying between the United States and Asiatic ports demonstrates the fact of rat infection perhaps in a more remarkable manner than any of the former.

A vessel left San Francisco early in the spring of 1901 for Asiatic ports, making the round trip in about four months; the vessel did not touch at any wharf, but discharged passengers and cargo well out in the stream. On her return voyage, a few days out from Honolulu, two deaths occurred between Honolulu and her home port. There being no physician aboard, nothing more definite than the master's statement could be obtained, but all pointed to plague. On discharge of the cargo no dead rats were found, and no information could be obtained regarding them from any member of the crew until finally the Chinese quartermaster admitted that dead rats were being found continually when the vessel lay alongside the dock in San Francisco, and were observed on several occasions on the outward voyage. Here was an instance where rats were dying as long as three months before any case occurred among the crew, notwithstanding these must have been in close proximity to the personnel. Other instances of the same character could be cited if it were deemed necessary.

I can not, therefore, bring myself to agree with the opinion of the British Plague Commission when it says: "There is no evidence that plague-infected rats have ever carried plague from one country to another, and that fumigation of holds of ships, in order to kill rats, is unnecessary and impracticable," or that there "is no confirmation of the suggestion that plague may be conveyed on board by embarkation of plague-infected rats."

It is indeed a fortunate circumstance that few of the vessels engaged in the trans-Pacific trade touch at any wharf in the Orient, and that passengers and cargo reach the vessels by boat. If it were otherwise it would be next to impossible to prevent these vessels from being infected on nearly every voyage.

Notwithstanding the present arrangement, the dissemination of plague has been very closely connected with some of these, and this is due more to their being infected with rats than to any other cause. Few rats, if any, get aboard these at Hong Kong, or at any other port, still these vessels contain numerous rats. It has been the custom since medical inspectors have been on duty at the Oriental ports to destroy the rats on board just after discharge of cargo by fumigation, but on the next voyage about the same number are on board. The question naturally arises, from whence do these rats come? The answer to this was the same from all, "American ports, principally San Francisco." The vessel is, therefore, subjected to a double danger from (*a*) cargo possibly infected, (*b*) and from infected rats.

With regard to the possibility of vessels becoming infected with rats at San Francisco, I may add my personal observations to that of the officers of vessels, whose answer to the query is quoted in the above. The wharves and water front are infested with rats in great numbers. The wharves are, as a rule, old, and of such construction as to be ideal vermin harbors.

These are some of the reasons explanatory of the way in which plague may be carried from place to place by means of vessels. A rat infection may exist comparatively for a long time before it is manifest, but just the same as on land. Places may become infected one after another by such vessels, and the circumstances attending its sanitary history be forgotten before the place awakes to the realization that it has plague.

### MARITIME QUARANTINE.

On arrival of a vessel from an infected port great care should be exercised in making the examination, and a diligent inquiry should be instituted regarding all that is essential in determining the sanitary condition of the personnel, cargo and vessel. The sanitary authorities should be given wide latitude in their determination of the fitness or unfitness of a vessel to be passed or to be held for treatment. The regulations for their guidance should be laid down on the broad principles of preventive medicine and not "line on line and precept on precept" of laboratory technic and unimportant details.

A few good rules are excellent, but rules enacted into law are still better, for regulations are not laws and can not have the force of law. The sanitary authorities should be experienced men, well qualified, and, above all, resourceful and possessing executive ability, and, moreover, endowed with a liberal amount of common sense. If these precepts are regarded, I feel sure that many of the hardships, both to commerce and the personnel of vessels, would be, in a great measure, removed, and the health interests of our country be better conserved.

In general, the same rules of procedure as suggested for cases on land are applicable for the treatment of a vessel, its cargo and personnel: The diagnosis, treatment of cases, surveillance of the contacts and the suspects, each with its appropriate treatment, and lastly, the disinfection of the vessel and cargo with the destruction of vermin.

The maritime quarantine stations at our larger ports are now equipped with all the requisite apparatus and conveniences for the treatment of such vessels with effectiveness and dispatch. A description of such stations will be unnecessary. One of the greatest safeguards to this country in preventing the introduction of plague is the present policy of the national government in detailing officers of the Public Health and Marine-Hospital Service for duty in the office of the consulates in the several Oriental ports. No one thing has been of greater protection than this, as it has prevented plague from being brought on board, and, moreover, practically relieved commerce of many of the vexatious restrictions which were necessary to impose before this was done.

With regard to the utility of the detailing of medical officers of the government in European ports, it is a question whether any great benefit would be derived from it. The conditions under which a sanitary supervision of vessels and their personnel would be maintained, would amount to but little. As a public health measure, it has practically not been appreciated by the trans-Atlantic traffic, and what little has been allowed to be done rests more on the fear of a quarantine on this side rather than being one of co-operation to prevent infectious diseases being brought to this country.

### MEASURES TO BE ENFORCED IN A PLACE INFECTED WITH PLAGUE.

As before stated, the prompt recognition of the first cases is most essential. A single case, for example, coming from a vessel or another place on land, if promptly recognized, would give us but little concern. But such instances are rare. It is usually not recognized, and one is not apprised of the fact until weeks, or perhaps months, afterward.

Plague is believed to have been introduced into Hong Kong from Canton at least eight or nine months before the cases were of sufficient number to attract attention by the increased mortality from "fever." Therefore, when plague is recognized as plague the initial focus usually has been lost. Further, it may, and perhaps is, in the majority of instances, introduced by rats, rather than by persons and their effects. This was true of the first and second epidemics in the Hawaiian Islands. Rats were observed to be dying in and around the wharves many weeks before the first cases appeared among the Chinese and native population. The last epidemic was directly traced to infected rats.

All rat plagues are not followed in direct sequence by human cases. These may exist for a long time and not be infective. On the other hand, they may occur just slightly before or be synchronously with the plague in man. Davis says: "Plague, when it is introduced by persons, may be readily exterminated; when introduced by rats, followed by the infection of shore rats, it has come to stay."

During the first great outbreak in Hong Kong, in 1895, rats were found dead in many of the houses occupied by the European population; yet but few of these houses became infected. In contrast with this, in 1901 the majority of the Europeans affected with plague was evidently due to infected rats, as these were found in nearly every instance. Nearly as late as 1900 the medical officer of health says: "It is also interesting to record that, although over 400 Chinese coolies have been employed regularly in scavengering and cleansing the city and in the disinfection of infected premises, and that practically the whole of the 42,000 dead rats must have been handled by these men, yet only three cases of bubonic fever are known to have occurred among them during the year." "In 1901," he says, "there were about thirty men who made a business of collecting these rats. and I find that no less than seven of them died of bubonic fever during the period under report, while five others left the colony because they were sick, and two of these later are said to have died of this disease on the mainland."

In Kobe plague first made its appearance along the water front just close by the place where the cargo junks were moored. The first recorded case, however. was not among those who lived on the boats, or, from what could be learned, had anything to do with the loading or unloading of vessels. It may have reached the shore through the agency of these junks, but, what is more probable, by a wharf at which vessels arriving from Kelung, Formosa, Hong Kong and Bombay discharged their cargoes. As soon as plague was recognized the work of its eradication was placed in the hands of Professor Kitasato, to whom all praise should be given for his great and noteworthy achievement in freeing Japan from plague.

Japan has so far been the only country which has successfully eradicated plague within a short time. The system adopted by the local and imperial authorities, while in some respects a rigorous one, has demonstrated that it is the only kind which is efficient. As Dr. Thompson has remarked: "There is no royal road to the prevention of plague." It means work, and hard work at that. Although much information has already been given in the published reports of the plague epidemics of Kobe and Osaka, there are many features and details of these which have not been set forth as clearly as they should be, and, therefore, are deemed of sufficient importance to describe some of these more fully. with the hope that a better understanding of the subject of plague prevention and eradication in Japan may be of service in our country, particularly in dealing with populations and conditions which may be similar.

In 1899 cases of plague were discovered among the population of Kobe which lived along the water front and contiguous to that part of the bay used by the cargo junks. Soon after the announcement of the discovery of the first cases, the imperial government sent a commission of experts headed by Professor Kitasato, which was empowered to co-operate with the local health authorities, and to take such action and adopt such measures as were deemed necessary to eradicate the disease. Immediately on assuming charge, an inspecting corps of thirty-six physicians was organized to make a thorough inspection of the city. Volunteers were called for, and as many as 380 physicians were selected and appointed for this work. These were divided into the following classes:

1. Inspectors for districts, whose duties were to see all cases of illness, it mattered not what the nature might be, to view and obtain the history of all those dead and report the same to the district superintendent.
2. A corps of inspectors for performing autopsies and making bacteriologic examinations of all persons dead suspected of plague.
3. A corps of inspectors whose sole duties were to make bacteriologic examinations of rats.
4. A corps of physicians to administer the anti-plague serum and Haffkine-Shiga prophylactic.
5. A hospital and ambulance corps to look after those sick with plague and those detained in quarantine.
6. A disinfecting corps, organized much in the same manner as a volunteer fire department.
7. A corps of rat inspectors detailed from the police force.

The plague made considerable progress in Kobe before the authorities were able to cope with it. It was decided from the first that all houses in which plague had occurred, or those contiguous thereto, should be destroyed, but the authorities were immediately confronted with a law which prevented the destruction of buildings by fire. It took some few weeks before this law could be modified, and so valuable time was lost. However, as soon as the law became operative, the occupants, with their contents, were removed under sanitary conditions, the houses razed to the ground, carried out by piecemeal and burned. In view of the success which the Honolulu authorities had in the dealing with plague, it was believed that this drastic measure would be all that would be required for the control of the disease. This, however, did not suffice. It is believed the reason why it failed was simply because of the interval between the time that plague was first discovered and the law went into effect authorizing the destruction of buildings.

Soon thereafter plague appeared in the central parts of Kobe and the adjacent municipality of Hiogo. Many of the houses in which plague had occurred were disinfected and allowed to remain closed for ten days before the occupants were allowed to return. In several of these houses plague again broke out. Professor Kitasato was at a loss to explain just what was the reason, because a most thorough surface disinfection had been made of the houses and surroundings. When these cases occurred another sanitary inspection was made and several dead rats were found in the walls and over the ceilings of the houses. These rats were in various stages of decomposition, some evidently having been dead for several weeks. A bacteriologic examination was made of all these, and in a few only the plague bacillus was isolated. A vigorous crusade was then commenced against the rat. In fact, it was contemplated to destroy all the rats in these two cities, and a premium of 5 sen (2½ cents) was offered for every rat brought to the police department, either dead or alive. Arrangements were made that those bringing rats should report to the nearest police station, where a full history of each rat was obtained. This plan was not successful—only a few rats were brought by the population, or caught by those specially designated for this duty. The superintendent of police of Kobe hit on a plan which was one of the most successful features of the anti-rat campaign.

It appears that several years ago the government interdicted gambling in all its forms in Japan. Now it is a well-established fact that wherever you find the Tartar blood you will find also an inherent desire to play at games of chance. For all these years the Japanese nation had been interdicted from gambling, and they were practically in a state of hunger for hazard; so the superintendent of police suggested that in view of the fact that as the people were desirous to play at games of chance, in addition to the price of 5 sen offered for each rat, the lottery feature would be added, and a cash prize would be awarded at stated intervals. Each person who would bring in ten rats was entitled to a lottery ticket and the prizes offered were: 100 yen, first prize; 50 yen, second prize; 20 yen, third prize; 10 yen, fourth prize; 5 yen, fifth prize; 1 yen, sixth prize.

As soon as this feature was announced, the number of rats brought in immediately arose from 1,000 per day to between 5,000 and 6,000 per day. So fashionable had rat catching become that people from the surrounding towns brought dead rats as a visitory offering to their friends in the city.

You can well imagine that the bacteriologists who examined rats were kept hard at work to examine from 5,000 to 6,000 rats per day. The number of rats that one physician could examine, a report was made, was not more than 200. This rat crusade developed some very interesting features. One was that in Kobe and Hiogo there was an intimate association between the rat cases and the human cases. Many times, however, the rat infection was not followed by human cases, and a few human cases were found in which there could be no connection traced between these and pest rats.

A short time after the epidemic of Kobe, plague appeared in Osaka. Osaka is the great manufacturing city of Japan, having a population of about 1,000,000. It is located about eighteen miles from Kobe, and is easy of access either by land or sea. In the city of Osaka, by reason of its location, the conditions were quite different from those in Kobe. The latter is a small, compact city, situated in a narrow strip of land on the sea, surrounded on three sides by hills; it is well drained and has a good water supply. Osaka, on the contrary, is spread over a large flat plain, intersected in every direction by canals. The intercommunication being very largely by water, the population was an ideal one in which an epidemic disease like plague would spread. Plague broke out among some of the workers of the large spinning mills, and it is believed now that some of the infection can be traced to plague-infected cotton brought from Bombay. However, be that as it may, the authorities immediately saw that they had a very much more difficult proposition than that of Kobe. In the first place, the commercial and manufacturing elements protested strenuously against any such drastic measures which were enforced in Kobe, and so great was their influence that there was, for the time being, a modification of the measures which had proven so successful in Kobe, and they were suspended and the former status re-established. The rat examination, however, went on as usual, and it was not long before pest rats were found in several parts of the city, and at places quite distant from the place where the first cases were discovered. Again sanitary measures were enforced, but soon brought to a standstill by the commercial influences. It was not until three separate and distinct outbreaks had occurred that the sanitary authorities were given a free hand. It was not long after this that the last case of human plague occurred, and the city has since been free of plague.

Some features of the campaign against the rat are not without interest. During the time of the cases there were, on an average, 5,000 rats delivered daily to the various police precincts. The number in 1901 was about 2,000 per day. From Nov. 20, 1899, to Aug. 23, 1901, there had been examined 565,589 rats, and of these only 158 were infected with plague. The last plague rat was found on June 21, 1901, one year and five months after the last case in man. There were 69,718 rats examined in Kobe and Hiogo between May 1 and Aug. 23, 1901, and two infected rats found—the first was discovered in March, the last on June 11, 1901. The last plague case was Dec. 21, 1901.

The long time elapsing between the last plague case in man and in the rat is quite suggestive and seems to offer an explanation of the recrudescence of plague from time to time in which the source of infection is unaccountable. Further, it emphasizes the fact that our measures against rat infection should be continuous, and for an almost indefinite time. In September, 1901, in conjunction with Dr. Bell of the Civil Hospital at Hong Kong, I made a bacteriologic examination of 251 dead rats which were collected by the scavenger force from all parts of that city. Without reference to locality where found, thirteen of these were dead from plague. Dr. Bell continued the examination of 100 each in October, November and December. He found for October 2 per cent., November 1 per cent., and for December none of the rats was infected. He says: "It is interesting to note that the subsidence of plague against human beings corresponds to that among rats. These examinations, while few, seem to establish the fact that one of the means, and what is believed to be the chief agency to not only disseminating plague but keeping it alive, is the rat. Certainly there was an intimate connection shown to exist between the rat infection and the cases of plague occurring among the better class of whites, who were living a considerable distance from the Chinese part of the city.

Whether the size or age of the rat has anything to do with the dissemination of plague, or whether it influences its virulence, can not be said. Of the number examined by us 124 were full grown, and of these 10 were infected; 63 were half-grown, and of these 3 infected. No young rats and mice were found infected.

We have already mentioned the fact that the temperature may have a direct influence in arresting plague, for it is a well-established fact that whenever the temperature reaches 81 to 83 F., and continues for some weeks, the plague mortality steadily diminishes. I have suggested that possibly the rat may be influenced in some way by the high temperature, maybe in a resting stage, and without inclination to migrate as at other seasons, and thereby may be less exposed to the infection and less liable to disseminate it.

Manila has now experienced two epidemics of plague since the American occupation. This focus of infection is almost of as much import to the States as the Chinese and Japanese ports. In October, 1901, soon after my arrival, the sanitary authorities began a systematic campaign against plague, and particularly with reference to the destruction of vermin. All rats caught, killed or found dead were examined. The anti-rat campaign developed the same results there as it had done in Kobe and Osaka. Plague cases became fewer, even at the season when there had heretofore been the greatest number of cases. Unfortunately, just when it seemed that a full control had been attained, cholera made its appearance, and the anti-plague measures practically ceased. Plague then began to increase.

There is yet a diversity of opinion concerning the rôle played by suctorial insects in the transmission of plague from rat to rat, and from rat to man. Simond's contention appears to be established by Thompson in the epidemic of Sydney, but so far this is the only instance where observations of this character have been confirmatory. Laboratory experiments made in this country and in Europe appear to establish the fact that fleas from an infected rat are capable of transferring the pest bacillus to healthy rats. Terni claims that the *Pulex fasciatus* infests both rat and cat, which sometimes infests man, while Gautheir and Raybaud's experiments show that plague can be transmitted from rat to rat by the *Pulex fasciatus,* and by a smaller species resembling the *Pulex irritans,* also that the ascarides sometimes infesting rats can also transfer the bacillus from sick to healthy rats.

In eight experiments made with fleas which infest man, by placing these on rats they were able to transmit plague from rat to rat, all of them were successful. Tidswell's observations[1] rather confirm Simond's contention. He says: "It does not follow that fleas harbored by the rats in two widely different places would be exclusively the same species. With a view of determining this, a collection of fleas was made from rats coming under observation. Of 100 fleas 10 were *Pulex fasciatus,* 8 were *Typhlopsylla musculi,* 1 was *Pulex serraticeps,* and 81 were *Pulex pallidus. Pulex pallidus* has not been heretofore mentioned. This species, as well as *Pulex fasciatus,* bit men; the others did not." In view of the fact that our observations are not as yet either sufficiently numerous or accurate, it would be as well to include the destruction of all insect life in our measures against plague until it is conclusively proven that these have no bearing on its dissemination.

Now with regard to the prophylactic injections for plague, it has, as is well known, been extensively employed in India and has passed the experimental stages. The epidemic of plague in Kobe and Osaka demonstrated that it was of greatest value in preventing its spread. Statistics are tiresome, but are, notwithstanding, sometimes necessary. The number inoculated from Dec. 12, 1899, to Aug. 22, 1901, was 110,115 in Osaka, and 30,000 in Kobe.

While the prophylactic injections were not made obligatory, many persons availed themselves of them, especially those who had been in contact with plague cases or where plague rats were found on or near their domiciles, and those whose avocations would be more likely to be exposed to the infection. The police and rat collectors were all inoculated—several hundred—and none of these contracted plague. One physician died of pneumonic plague—he was not inoculated. This is quite in contrast to the rat coolies of Hong Kong, where many died of plague. The Yersin anti-pest serum was administered to all those who were in direct contact with cases, and in not a few instances to those who had come in contact with pest rats. In none of these did plague occur. From last accounts from Japan, the campaign of the sanitary surveillance still goes on, and it is the intention to maintain this so long as there is danger of plague being a menace to that country.

---

[1] This observation appeared after presentation of paper, Jour. Trop. Med., July 15, 1903.

The measures to be enforced in a port infected with plague must of necessity be modified in their details, according to the exigencies of the case. No better plan has been devised than has been adopted by the Japanese and Australian authorities in the management of their plague epidemics, which may be summarized as follows:

1. Detection of cases and of rats infected.
2. Provisions for the care and treatment of those sick.
3. Isolation and surveillance of contacts and suspects.
4. A general inspection, personal and domiciliary, of the place by a sufficient number of trained experts.
5. A general destruction and examination of vermin for plague.
6. The offer of prophylactic inoculations and immunization to all persons liable to be, or have been, exposed to plague.
7. Disinfection of personal effects and of domiciles presumably infected or liable to become infected by vermin.
8. Preventing persons exposed to plague leaving an infected place until free from infection.
9. A sanitary surveillance over the common carriers.
10. A coöperation between the sanitary authorities, national, state and municipal.
11. Publicity.

"Plague is regarded by nearly every citizen as a possibility elsewhere, but not in his own particular city. The same note of resentment is struck in nearly every place where it has appeared. In Oporto, Bombay, Alexandria, Osaka and San Francisco the same old story is repeated. The commercial interests resent the imputation, and those who have announced the unwelcome news have been regarded as public defamers of the city in which they live."[2]

There are a few notable examples now on record which stand out in vivid contrast to the above, as is instanced by the action of the sanitary authorities of Japan, Sydney, Hong Kong, Glasgow and Mexico. Not only the simple announcement was made to the world, the regrettable fact of the appearance of plague in their city or country, but also that they were doing all that could be done to eradicate it. Whether success speedily crown their efforts or not did not rob them of the commendation, the assurance of coöperation or of the confidence and esteem of all countries.

It was indeed a lamentable fact that some of our citizens could not have seen their way clear to have been honest and upright, and to have adopted a proper course of action on dealing with plague soon after its discovery in San Francisco, instead of inviting disaster not only to themselves, but to the whole country, in their short-sighted policy of denial and suppression of the truth. We are confident that if the same amount of energy had been directed toward the eradication of plague as was displayed in attempts to obstruct and hamper the sanitary authorities, and in means of suppressing information, plague in the United States would have long since ceased to be a menace, and also there would not have been entailed the crime of sacrificing human lives for no other reason than to conserve and promote their commercial and political prestige.

It was a most humiliating spectacle! Misrepresentation, duplicity, fraud and suppression of truth were the watchwords emblazoned on their banners. The sanitary authorities of nation, state and city were opposed in everything they attempted to do. Attempts were made to suppress information, even reports sanctioned and made mandatory by the highest laws of our land, and in more than one instance their campaign was successful. There arose at one time what appeared to be the turning point in this tide of civic corruption, when reason and common sense would replace the foolish ostrich-like policy of the past, whereby the sanitary authorities would be allowed to discharge their duties without further hindrance. But the representations made by these obstructionists were so plausible (?), their promises and agreements really having the smack of sincerity, that a few were so blinded by their glamour that they fell an easy prey, and, like Samson of old, blinded and manacled were led forth captive to furnish sport to be mocked and jibed by these modern Philistines. The simile here ends. The house still stood. But plague, like Banquo's ghost, would not down. It held the even tenor of its way, gradually extending its territory, despite the plan of campaign, and could not be exorcised either by executive bulls or judicial opinions, even when loudly proclaimed by a venal press.

It is believed that from the very first the now Public Health and Marine-Hospital Service had no other desire than to do all that was possible to eradicate plague from California, and, while mistakes have been made in directing its policy, no one will doubt its sincerity in sanitary work. But this service, like those of the state and city, was also incapable of escaping the clutches of the great organized combination of commercial and political interests; consequently its efforts came to naught. Probably more would have been accomplished in the beginning had it not undertaken too much and had been more mindful of the statutory and constitutional limitations between state and nation.

The same story was repeated over and over again, and no progress whatsoever was made in the eradication of plague. It was, so far as the combination was concerned, an endless chain of falsification, duplicity and sordid self-interest—a travesty on civic decency—a monumental disgrace. Just how long this condition of affairs was to continue, despite the protests of honest people, none could foresee. It appeared to resolve itself in awaiting a time when those of San Francisco and California could by some yet undiscovered means or new procedures be brought up out of the mire, and be made to see the error of their ways, and be compelled to do something to eradicate the plague spot from their midst before it still further menaced the whole country. It did appear questionable whether anything would be permitted, until a sufficient number of cases had occurred to cause a panic and commercial disaster. Perhaps then they could be awakened from their self-satisfying dreams, would arise, clean their city, make the Chinese put their houses in order and keep them clean, or go.

The sanitary authorities of San Francisco and some of the state deserve the lasting gratitude of the nation. Too much praise can not be given to those who have constantly and fearlessly discharged their duties, despite the almost insuperable obstacles thrown in their way. The recently enacted law reorganizing the Marine-Hospital Service into a Public Health Service contained, among other things, a provision for a conference between its chief and the state health officials, to be held on the demand of five or more states or territories. Some of the health authorities, together with the writer, believed that steps should be immediately taken looking to a concerted action of the state and national authorities whereby plague could be eradicated.

---

[2] British Med. Jour. Editorial.

The preliminary steps to this end were taken by the Conference of State and Provincial Boards of Heath at its annual meeting at New Haven in October, 1902. The resolutions unanimously passed by that body were of such character that a conference between the surgeon-general of the Public Health Service and the several states was a natural sequence. This conference was held in Washington early in January, 1903, and resolutions passed by this body reiterated those passed at New Haven, and further spoke in terms of no mistaken meaning to those who had persistently balked every well-meant effort to clean San Francisco's Chinatown of plague, that the time had come when they must cease "to quit their meanness," tell the truth and be good.

All these things they are doing or have promised to do—the very things which were suggested to them in 1900. Now the city board of health is not being interfered with. The state authorities, together with the United States Public Health and Marine-Hospital Service, are aiding it, and a hearty co-operation established between all, each doing its allotted part.

It does seem as if this is the beginning of the end, and that after conscientious and persistent effort that the danger of a further extension of plague will be dissipated, and that soon the painful memories of the past two years be sunk into oblivion. Let us hope that the era of good feeling, plain dealing, honesty of purpose, and above all, good citizenship, may have come, and be established among those who have heretofore been guiding the destinies of a great state.

## DISCUSSION

### ON THE PAPERS OF DRS. CALVERT AND KINYOUN.

**Dr. F. G. Novy**, Ann Arbor, Mich.—The history of plague, to my mind, forms one of the most interesting chapters in the history of epidemics. Nine years ago the telegraph reported the existence of plague in China, and when the news reached Europe there were very few physicians who had the slightest idea as to what the plague was. At all events, it was extending, passing through and beyond the chief empires of the Orient; in time it reached South America, North America, Africa, etc. At the outset France and Japan sent commissions to investigate the disease. These commissions were headed by Yersin and by Kitasato, respectively, and they worked independently and at the same time in Hong Kong. The announcement was soon made that they had both discovered the plague bacillus. As a matter of fact, to Yersin, and not to Kitasato, belongs the credit of this discovery.

In plague we have a well-defined disease, caused by a well-defined organism; this organism can be seen easily under the microscope and can be easily found in every case brought to the postmortem table; and, moreover, it can be cultivated without difficulty. Experiments can be made on animals and the relation of the germ to the disease can be demonstrated to anyone.

The question naturally comes up: "How does it get into the body?" There is one point which I should like to emphasize, and that is, that plague is essentially an animal disease and is primarily not a human disease. It affects by preference animals, rats or other rodents in China, and these animals introduce the disease into the human subject. How? The flea is commonly held responsible for such transmission, which, however, is by no means absolutely proven. To my mind, other insects may take a part in and other means exist for its conveyance. The usual mode of entry is presumably through an inoculation wound, but it is exceedingly difficult to indicate just where the bacillus enters the body.

As to the germ, we may say that its virulence decreases when it is kept in ordinary culture. The organism is not so very resistant and is readily destroyed by various injurious conditions and substances. Several types of the disease are met with according to the manner of entrance of the germ. The most common type, where the lymphatic glands are enlarged, the so-called bubonic form of plague, probably results as I have indicated, by inoculation through wounds. The pneumonic type follows the entrance of the germ along the respiratory passages. A third or septicemic variety is at times met with. The mode of entrance, the virulence of the germ and the resistance of the individual are determining factors in the production of a given type of the disease.

I wish, though, to especially emphasize the prevention of plague by vaccination methods. In addition to these means we have, of course, methods of disinfection, the isolation of the sick, the segregation of those exposed; all of which are powerful means for controlling the disease. There are two methods of vaccinating against this disease: First is Haffkine's vaccine, which is prepared by growing the plague germ in beef tea. When such cultures are fully developed the germs are killed by exposure to heat, and the material thus obtained is ready for injection into the human subject. The immunity thus acquired by the individual is fairly lasting. A second method of vaccination consists in the use of Yersin's serum. This, when injected into the human subject, has a curative as well as an immunizing action. It is prepared by injecting plague bacilli, of the most virulent type that can be obtained, into the horse. The animal thus immunized gives a serum which is strongly protective, but the duration of such immunity is not as long as when Haffkine's vaccine is used. I believe that Yersin's serum, when properly prepared and not too old, when used in sufficient amount and in the right way, will give perfect results. Two years ago we had a case of plague infection of accidental origin in the laboratory. One of the students, in some unknown way, inoculated himself while engaged in making vaccines. He developed the pneumonic type of plague. The onset of the disease was sudden and severe. My attention was called to his illness about twenty hours after he had taken to bed. Pronounced evidences of the disease were found, such as high temperature, anxiety, respiratory distress, etc. An injection of the Yersin serum was given at once. Preparations were made at once from the throat and from the material coughed up, but these showed no germs. Within the next two or three hours a blood-streaked particle of sputum gave positive evidence of the existence of plague. The fellow was removed from his companions and taken to an isolation hospital. His condition was unfavorable to say the least. The young man had the pneumonic type of the disease, which form has a mortality of just about 100 per cent. One hundred and twenty c.c. of Yersin's serum were injected into the patient; of this 60 c.c. were given intravenously and 60 c.c. subcutaneously. Within twenty-four hours the temperature dropped from 104.5 to 100 and he improved greatly. Apart from a marked cardiac weakness which persisted for several months, he made an uneventful recovery. This case clearly shows the efficiency of the serum when given in large quantities and right into the circulation.

In connection with this subject I should like to say that it is exceedingly difficult to find the first case of plague which appears in any locality, simply because we are not expecting it and because it may be mistaken for several other diseases. It is very essential that the utmost care should be exercised in looking over suspicious cases, especially when one is in a locality where the disease is not known to exist. Early recognition means a relatively easy eradication. When, however, plague does establish itself it is exceedingly difficult to stamp out. We know that there is hardly another disease which is so difficult to eradicate as this one, and this is probably due to the fact that the germ lives in the animal body and thus keeps up a local focus for the spread of the disease.

**Dr. Emmet Rixford**, San Francisco—I do not know why I have been called on to speak before this meeting as I do not pretend to have a knowledge of bubonic plague. Though I reside in San Francisco I have never seen a case. If, however, you call on me as a sort of representative of San Francisco to say something from her side on this matter of the alleged concealment of the presence of the plague, a matter which has filled the medical and lay press for many months, I might be emboldened to occupy your attention for a few moments. San Francisco is not proud of the position in which she finds herself obliged to bear the taunts and sharp criticism of the guardians of the public health on the Atlantic coast. But there is something to be said on her side. She feels that she has not been quite fairly treated. It is, of course, hard for you to appreciate that much of the trouble was due to the local political situation in which you can have no interest, but such is the fact. There is no doubt in the minds of most of our local profession that had it not been for the extreme positions taken by rival and opposing political factions the sensational elements of the matter would have been largely avoided. The statements which received greatest publicity were exaggerated and far from the truth on both sides; the great mass of substantial citizens and the conservative portions of the medical profession were not heard in the controversy. Much has been said as to the domination of the commercial interests. Certainly the Merchants' Association of San Francisco, which is representative, did not at any time deny the existence of the plague. What San Francisco feared was quarantine. What she denied was the justification of quarantine, which was not only threatened, but in the case of two states was actually inaugurated against the state of California. At no time have the facts in the case warranted even the threat of quarantine. Quarantine is a frightful punishment to mete out against a community; it is justified only in the demonstrated presence of widespread and progressing epidemic. I am told to-day that the boards of health which met not long since had no real intention of placing quarantine on the state of California, that they used the threat merely to bring us to our senses and that the matter of possible quarantine would never have been suggested had the medical profession of California openly acknowledged the presence of the plague in San Francisco instead of denying it. The facts are that the medical profession of California in session of its State Medical Society two years ago did, by resolution, put itself on record as recognizing the presence of the plague in San Francisco, and the fact was widely published in the medical and lay press. It is now three years since the plague was discovered in San Francisco, and in all that time there have been but 90 sporadic cases, and these, with but two or three exceptions, confined to the Chinese race. At no time has there been an epidemic of plague in San Francisco, or anything approaching it.

There is another thing which seems to me to have considerable meaning in extenuation of this unfortunate controversy, and that is the fact that the world knows a great deal more about the plague to-day than it did even two or three years ago, and that had the present knowledge of the subject been generally disseminated when the plague first appeared in San Francisco the efficiency of preventive measures would have been appreciated, the comparatively slight contagious characters of the disease would have been recognized and the hysterical statements which set the whole United States agog would not have been made, and intelligent effort would earlier have been directed to the eradication of the disease. Happily now the situation in San Francisco is more satisfactory; there has not appeared a single case for more than two months, and the officials of the United States Marine-Hospital Service and the local and state boards of health are working in harmony, watching and fighting the disease, and it is to be hoped that we can soon say that the disease has no longer a focus in San Francisco.

Dr. W. J. Calvert, St. Louis—There is one feature of prophylaxis of plague which I should like to mention, namely, the dangers of Oriental infected centers or plague centers. In Canton and Hong Kong plague exists from year to year with practically no steps taken to check its propagation and dissemination. The present pandemic practically originated in Canton, to be distributed from Hong Kong to other parts. Even if plague could be quickly and effectually eradicated from San Francisco, Mexico, etc., it would soon be reintroduced from Hong Kong. It seems to me that in discussions on the prophylaxis of plague too little attention has been given to these sources of the disease. As long as they exist the world is exposed to infection. I think we should try to improve the hygienic conditions in these centers by properly educating the Chinese, who at present know nothing of modern medicine. If properly approached they would be only too willing to lend a helping hand to rid their people of this pest, and at the same time the outside world from the danger of infection.

---

# THE HISTORY AND ETIOLOGY OF "MIGRAINE."

GEORGE M. GOULD, M.D.

PHILADELPHIA.

*(Concluded from page 172.)*

*The Eye and Migraine.*—For several thousand years the observation has been unconsciously persisted in that the cephalalgia is not a head-pain, but an eye-pain. Few or none in any definite way noticed that it was produced by near-use of the eyes, and none that the various extensions to other parts and organs, the intensifications of the pain, and the masking under a hundred other protean disguises, were also products of continued and increased eyestrain. But there was never any failure of the necessity to notice the implication of the ocular factor. The most noteworthy after the eye-pain was, of course, scintillating scotoma. The seat of this strange disorder has been placed in every part of the visual apparatus from the retina to the ultimate of the visual center.[1] Piorry's theories of "monophthalmalgia" or "iralgia," or of an affection of peripheral nerves of the eye, was followed by Brewster's thought that the retina is the organ affected. Airy, Förster and Liveing placed it within the cranium, the latter, with Wollaston, locating it in the thalamus. Mauthner argues against the cortical localization. Dianoux thinks the source is in the optic nerve, the chiasm, the optic tracts or the geniculate bodies. Baralt returned to the retinal theory and Féré defended the cortical localization. Possibly the mixture of phosphene symptoms helped to create the diversity of opinions. It has also been noticed that the typical fortification spectra is of great variety; that often it is not colored or quivering, etc.; that it does not have any uniformity of location or appearance; and, finally, that it is often not a positive phenomenon at all, but merely a negative one—"aphose," "anopsia," "vision nulle," etc. There may be a failure to perceive the image in varying degrees, in various parts of the field, and for varying lapses of time. "Blind headaches" the patients speak of in such cases. Spitzer is in error when he says all scotomas are positive, the products of irritation. I have had many patients who, on being narrowly questioned, bear witness to the negativity of the visual difficulties. Neither is it always binocular, as he contends. Theory is abundantly contradicted by observation when he says that "the visual aura of migraine is an irritation symptom, a binocular homogeneous hemiscotoma." Siegrist contends for the purely negative character of all migrainous scotomas, and believes they are of cortical origin. And such beyond question they are.

But wherever may be the location of these disturbances, they are visual in character. Thus what is recognized as the most frequent aura or initial symptom should have pointed to the visual function as the source of the mischief which it ushers in. In other diseases such a symptom dictates the location of the trephining of the skull. In migraine it is held as without suggestive value.

---

[1] This has been elevated into an independent disease, especially by Galezowski and Féré. Charcot, Airy, Latham, Listing, Förster, Mannhardt, Ruete, etc., have especially commended or emphasized the special treatment of this form of migraine. The results are naturally *nil*.

Some 300 years ago Lepois, in beginning the study of medicine, found that he was greatly afflicted with migraine. He endured the attacks for four years and then, as thousands have done since, he fled to Italy. With cessation of study and with the out-of-door life he led, he soon recovered, and thought himself rid of the disease. But when he went back to his home and literary work the attacks returned as bad as ever. He naturally sought an explanation of the mysterious affection, and found it to consist of a serous exudation produced by vomiting. Since his day the same persistent cause has inevitably produced the infinitely multiplied result, but to the fact all have been blind, and all have multiplied theories as misleading and groundless as that of Lepois. And yet medicine is said to be purely empiric. The cause has been ever before and in their eyes, and empiricism has failed. And yet medicine is said to be a science, although none has observed the simple fact always present that near-use of astigmatic eyes is absolutely required to produce migraine. In the last century arose a so-called "cure" for migraine or for suffering eyes, atropin in the eyes, when, rarely, the eyes happened to suffer in migrainous attacks. Nietzsche was put through this cure. It acted as successfully as the other prescriptions, "Italy," or "Switzerland," or "walking the moors." But the cure did not last. The patient's ills returned when the mydriatic or the "change of climate" had ended, and there was return to literary work. Later, Brewster reports three cases of cure that really cured. He credits it to atropin, but ends the report of each case with the incidental remark that glasses correcting the ametropia were also prescribed!

Migraine or hemicrania, when we inquire with accuracy either of the literature or of private patients, is almost always not cranial in any common acceptation of the term, but is ocular. The fact that gave origin to the word is that not the skull, so much as the eyebrow, temple, eye and orbit, is the small portion where begins the headache, and whence with ingravescence, radiates or extends the disease to all parts of the head, the nervous and digestive symptoms. A large proportion of all so-called and recognized "ocular headaches," perhaps, have the same initial symptom and location. A great theory of the nature of the disease, migraine, was that of Piorry, which supposed that the neuralgia started from the nerves of the iris and was pathologically reflected from the cerebral sensitive center to other organs, from which reflex came all the symptoms and results of the subsequent disease. When the time and the state of medical science are considered, this showed a remarkably close observation and a near guess at the truth.

Other references to the eyes are, "anxiety about college examinations," "troublesome letter writing," "a rapid succession of visual impressions (in traveling) in upsetting the sensorium, and producing a vertiginous state allied to sea-sickness." Glaring lights, "sight-seeing," "an evening entertainment" have, of course, been noted. "Reading on a full stomach" caused the attacks in a great physician, and he could thus produce an attack instantly. Two young ladies always brought on the attacks by reading late at night. Incidence of strong light, a reflected light from snow, ice, a tablecloth, are also put as causes. In Dr. Airy's case the attacks generally came on "while the eyes are engaged with troublesome reading." It was so with Dr. Piorry, who could produce the disease experimentally "by strongly fixing the sight on reading." Looking at striped wall-paper, or a striped dress, a trellis, etc., are other causes, but it aroused no attention to astigmatism or the eyes in the physicians who chronicle the fact. Liveing's comments on these causes of the "nerve-storm" and the "habit" of migraine are most instructive—at least for us of to-day. Pity they were not more so to him. Liveing notes that dressmakers and others compelled to work far into the night, often for weeks together, complain of migraine. He does not fail to explain it by the "close and confined rooms."

It is set down that "mental exertion"—it is not called study—especially in lads at school and young men at college often causes the first development, or at least the increase, of the malady. "Close application to books," "and those modern instruments of torture, competitive examinations," are emphasized—"especially if coupled with deficiency of out-door life." "The same thing," says Liveing, "happens in later years to literary and professional men," especially between 30 and 40 years of age. But "overwork and over-anxiety in business" are, in these cases, the causes. "Students' life and intellectual competition," not eyes, are the supposed factors. "In Mr. A.'s son the early strain of school life caused the 'day-nightmare,' which preceded his megrim, and his subsequent attacks of the latter complaint were always multiplied by close application and almost ceased with an out-door life. It was much the same, though commencing at a somewhat later period, with his father and uncle." Dubois Reymond found his own attacks subsided when he had leisure to stop severe intellectual work. In one of Liveing's cases, "a child of 9 had been overworking at school, and on returning home early with a headache, etc." Another boy was 13 or 14, and to overapplication at school was ascribed his attacks. Of thousands of boys the same might now be chronicled.

But among many other things pertaining to the eye the most striking and convincing demonstration of the ocular cause of migraine, and at the same time one of the most remarkable instances of scientific error, is that of Dr. Alexander Spitzer. In 1901 he published a most erudite and critical monograph on the disease, the conclusion of which is that stenosis of the foramen of Munro is its unique and universal pathologic basis! This bizarre theory, the latest result of critical science, does not need a word to demonstrate its absurdity. One can only ask, why the inveterate disinclination to ignore the eye itself?

In his great work, Allbutt, like many others, notes that migraine is of exceptional frequency among those pursuing sedentary or in-door occupations, and rarely in those living an out-of-door life. The treatment is, therefore, advised to live much out of doors. But Allbutt and his departmental writer, Mackenzie, has no allusion whatever to eyes in the article.

In 1888, Dr. G. Martin (*Ann. d'oc.*, 1888, xcix, pp. 24 and 205), a French oculist, published an article which some time will be recognized as truly epoch-making. But two writers, so far as I have noticed, have even mentioned Martin's magnificent and daring attempt to bring the medical world to its senses. One of these, Spitzer, passes Martin by with a one-word mention of his name. The second, Schmidt-Rimpler, himself also an oculist, scorns Martin's theory with genuine unscience.[2]

One day Martin happened to get one of the astigmatic lenses of his own spectacles reversed, or "hindside-before," as patients often do, and he had a violent attack of sickheadache. This has frequently occurred with my patients, with the same sudden appearance of "the disease whose nature is unknown." Martin happened to possess the power of observation and to be a scientific scientist. From his own experience he was led to study that of his patients, and it was soon evident that their migraines were due to astigmatism, i. e., to partial and too continuous contraction of the ciliary muscle. When a single eye was astigmatic, and the other not so or less so, the pain (hemicrania) was over the astigmatic eye. With loss of one eye the bilateral migraine (if one may be excused the absurd term) became unilateral. When only one eye is used in vision, if it is the less astigmatic, the migraine is on that side. With cataract operations on both eyes the whole migrainous troubles disappear instantly, because there was then no function or malfunction of the ciliary muscle. (Surgeons and scientists should not, therefore, advise extraction!) Martin reports many cases of cure by spectacles correcting the ametropia. As to heredity, he counters capitally that the corneal abnormality (astigmatism) is as often hereditary as the incriminating diathesis. Of course, a headache can not be inherited, but only the anatomic, or other conditioning cause of headache.[3] The diathesis or constitutional factor determines whether existing astigmatism will produce migraine, and just what its nature will be. Martin reports 352 cases. Low astigmatisms, of course, are the rule—just such as the inattentive European oculist frankly ignores and scorns. There were, for example, in one series: 66 cases with 0.25 D.; 121 cases with 0.50 D.; 77 cases with 0.75 D.; 18 cases with 1.00 D.; 2 cases with 1.25 D.; 1 case with 1.50 D.

In higher degrees, as we know, there is no attempt to neutralize the corneal asymmetry and so no reflex disease. Near-work occupation is renounced, study interdicted, the eyes ruined, or a criminal life confirmed, but there is no migraine.

The morbid science which made the profession utterly ignore the testimony of S. Weir Mitchell published thirty years ago, made it overlook Martin's most valuable and scientific contribution. The great mass of medical men smiled and passed on after the manner of the leaders who knew so much and yet who knew so little. But the quiet protests and reports of other oculists began to appear, especially in America, and better still, thousands of patients began to tell thousands of their friends that "glasses cured my sickheadache." The doctors kept on with that wonderful smile, but it is now becoming more concealed and if exposed to public view, more sneery and much more sickly. The professional leaders, the text-book makers, the monograph-writers, especially if of European origin or tradition, have the smile thoroughly out of sight. In fact, they never smiled. Their books know nothing of eyes. In our country the bookmakers, as a concession to popular superstition and in order to be on the safe side, and to show they do know about all this sort of thing, make a lofty allusion to the ocular factor and treatment, but in a given case in their office they would no more think of directing the patient to an oculist than to a corn-doctor. Osler goes so far as to say that many headaches are from eyestrain; that many of these are hemicranial; and that in migraine the eyes should be examined. Tyson barely alludes to eyestrain, Anders also notes it, but in treatment he ignores it. French and Monro say eyestrain is a cause. The "New International Encyclopedia," volume of 1903, gives eyestrain as one of the causes of migraine, but fails to mention the fact under treatment. At present, all over the United States, there are quiet, almost unknown oculists who are curing thousands of patients of the afflictions described in the 14 historic instances of the two volumes called "Biographic Clinics." Hardly a week passes that noteworthy testimonies are not printed in medical journals by honorable oculists, that the eyes are a powerful factor in producing sickheadache and various morbid reflexes. Many other oculists do not publicly testify, and are afraid to acknowledge either their belief or the facts privately, for reasons which all consultants and referers of cases well know. There is an old disease called "Being between the devil and the deep sea." Thousands of American patients have learned that good refraction cures and prevents sickheadaches and many other miserable diseases. But their official medical advisers derisively smile that old-time, tired, sneery, sickly smile. The young and timid physicians, specialists or generalists—the great mass of the half-convinced or well-frightened—find themselves on a very narrow strip of an island or peninsula. On one side is water, deep, cold and far-reaching; on the other is what the polite little girl in her prayers called "the gentleman from hell."

*The Relation to Age, Sex and Occupation.*—From of old it has been noticed that migraine rarely appears before the age of puberty, and that with old age it disappears. But I am sure that it occurs more often in childhood than is supposed. Gowers goes so far as to say that one-third of all cases begin from the fifth to the tenth year. It all depends on the existence of ametropia and the amount of study, reading, etc., carried on. I have had a large number of school children afflicted with the malady in variant and typical forms. One little boy I particularly remember whose astigmatism for years increased about 0.5 D. every few months, was each time relieved of his intense vomiting by a change of glasses until the compensation of the higher astigmatism again became impossible. Puberty has nothing to do with the existence of the disease in either girls or boys. In the same way one of the superstitions of the ages appears in physicians' offices, both in patients and physicians, that with the menopause there is a sudden rising or exacerbation of many diseases, chief among which is migraine. The menopause has nothing whatever to do with this, which is wholly due to the increase of the ocular reflexes caused by presbyopia. The blunder should long ago have been manifest to the crudest observation.

There is no causal relation between the sexual history and organs and migraine. The old observation that women are more subject to the disease than men is also explained by the fact that women have always in the past done more near-work with the eyes than men—sewing, house-life, cooking, weaving, reading, etc. Whenever men pursue such occupations the disease is proportionally as frequent, modified slightly by their greater neurologic and temperamental resisting power.

---

[2] This distinguished specialist rightly finds "glasses do not cure," because he fails to see that he has never prescribed proper glasses for his patients. The astigmatism, ametropia, etc., must be corrected in order to cure, and such correction is beneath the dignity of the German oculists. Patients so report and books and articles frankly confess the fact.

[3] "A man bored a hole in a tree and a woodpecker came and lived in it. 'The tree has conceived' said the man, 'and has brought forth a bird.' Next year the woodpecker went away and two flying squirrels lived in the tree. 'What a curious thing,' said the man, 'is heredity.' "

The books and monographs also speak of the *great* incidence of the affection among the upper classes, the liberal professions, men and women of letters, etc. As the French say, *La migraine est le mal des beaus esprit.* This means only that such people read and write more than others. I have never heard of a case of sickheadache among farmers, policemen, firemen, soldiers, ranchmen, trainmen, cattle dealers, and drivers, sailors, etc. But among seamstresses, typewriters, typesetters, latheworkers, watchmakers, book-keepers, copyists, sewing-machine girls, weavers, etc., the disease is as common as among students, literary workers, educated people, etc.

An amusing and long-drawn out correspondence and discussion occurred in one of the London papers in November and December, 1903, on "Brain-fag." Almost every line showed that "brain-fag" was caused by use of ametropic eyes, not by use of the intellect.

As to periodicity, when the life has been forced into regularity and routine, there is sometimes an approach to regularity of rhythm in the attacks. But in another case and in the same one if ocular rest is secured, even for a day, the return of the attack is replaced by health and happiness. The length of the attack may thus vary from a few hours to almost any number of days. The interim of freedom varies with each patient and with the ocular labor of each patient, from a day or two, to once in a lifetime.

*The Gastric Crisis.*—Inaccuracy of observation is shown in the descriptions of gastric symptoms by many writers. In the first place there should be a distinction drawn between nausea and vomiting. Many patients will have nausea only, not followed by actual vomiting, and it is the testimony of most patients that this nausea is far more agonizing than vomiting would be—that emesis would bring relief. On the other hand, there is not seldom intense retching without any or but little vomitus. This is worse than either of the other two kinds of sickness. The difficulty of understanding what actually takes place in a given case is enhanced by the disinclination, especially in literature, of patients to state that actual vomiting took place. They use euphemisms, "malaise," "nausea," "sickness" and many indefinite or misleading terms. One's doubt is heightened by the difference in different countries, and even in one country in the significance of the word "sick" and "sickness." Many writers state that the gastric complication comes on and ends suddenly, and with the vomiting there is immediate return to the normal state of health. But constant retching and digestive misery sometimes persists for one, two, and even three days.

Then there is the failure to notice that the nausea and vomiting are but the latest and severest stages of the one disease, brought on by continuous application of the eyes, regardless of the prodromal and cephalgic warnings. Parkman, Huxley, Browning, Spencer, Carlyle, heeded the warnings and avoided the results; Nietzsche, Mrs. Carlyle, Margaret Fuller, George Eliot and Wagner did not heed, and their lives were tragedies. There is also wanting in reports the recognition of the striking fact that patients with the severe gastric disease, sickheadache, which produces vomiting, indigestion, anorexia and anemia, are able and are irresistibly compelled to walk five, ten or fifteen miles a day, or take some other form of exercise; and they are able to do it with ease and with the most manifest relief of all symptoms. In what other organic or severe stomachal disease is this possible?

*Colds, Rheumatism, and Gout.*—In private practice the careful and scrutinizing oculist finds that common colds and influenzas have a strange connection with eyestrain, and the relief of these conditions often follows the wearing of glasses. A misplaced or wrong lens strangely results in "a cold." In the cases studied in "Biographic Clinics," there are many confirmations of the fact. Mrs. Carlyle's "eight influenzas annually" is an instance, and all through the biographies of several of these cases colds and influenza are mysteriously present. It is exactly the same with rheumatism and gout. I have found no accident or cause ascribed for Parkman's life-long arthritis. The accounts of Nietzsche's "rheumatism" and that of the other patients are likewise both mystifying and suggestive. Sir Henry Holland is the great advocate of the theory of the gouty origin of migraine. To excess of uric acid in the system he and many others ascribe the disease. Because migraine as an "independent disease" is in reality due to eyestrain, the only conclusion to be drawn is that eyestrain often causes gout, rheumatism, and the "uric acid diathesis." To that conclusion, medical science may sometime come.

*Pareses, Paralyses, Anesthesias, etc.*, are most constant, frequently reported, and remarkably peculiar symptoms, concurrent or resultant, in the history of migraine. The following are the words of some of the reports: "The right arm becomes numb in the paroxysm, and in consequence so useless that she will let things drop from the hand." "Numbness and a sense of tingling (like that in a foot or hand 'asleep,' as we say, and 'pins and needles') commence in the fingers of the right hand and gradually extend up that arm and side, until the throat is reached. The interior of the throat, the tongue and lips seems to share in the sensation, which is no longer confined to the right side, but affects these parts bilaterally. The speech is next implicated." "It is utterly impossible for me to speak." "This disorder of speech is like that of some other highly educated patients." "An arm or a leg of the same side, one time one side and one another, go to sleep." "I feel a tingling as if ants were on them. I have the same feeling in the mouth and tongue, and, further, during this period, I have the greatest difficulty in speaking." Disorders of sensation and touch were present in 21 out of 60 cases in one series, sometimes alternating with disorders of sight. A distinguished physician, Travers, describes in his own case the numbness in fingers and tongue, so that touch and taste were muffled, etc. Piorry speaks of "painful thrilling," vibratory in nature, "uselessness of the hands," "transient hemiplegia." The description of Nietzsche's "rheumatism" creeping up the arm, etc., and others may be construed as the explanation of popular and permitted pathology. In private practice I have often noted these disorders of motility and sensation as dependent on eyestrain, and if, as I am convinced, migraine is caused by eyestrain, there can be but one conclusion of the matter. The overlooked little and contemptible cause, just as in daily life, is also the secret of pathology and practical medicine.

*Ocular Paralysis.*—Transient paralyses and pareses of the ocular muscles are well-recognized effects in migrainous histories. "Of the internal rectus of the right."

"partial of the oblique," ptosis, etc., are explained as inhibitory phenomena. Double vision, of course, is the result of these ocular paralyses.

*Psychic Disorders,* not alone those naturally resulting from long and intense suffering, but such as temporarily and directly are the immediate consequences of the disease, are frequent in all the literature of migraine. Confusion of intellect, temporary loss of memory, inability to speak, or to speak intelligibly, embarrassment, etc., are frequent expressions. It is noteworthy that these are usually concurrent with anesthesias, paralyses, pareses, etc. "Confused and tumultuous mental and emotional conditions" are the most frequent effects. Hallucination is rare. Professor Lebert's severe seizures began with "incoherence of ideas and difficulty in finding words." "Strange and wandering in his mind;" "unable to collect his thoughts;" "mind affected;" "mentally incapacitated;" "whatever he read left no impression;" "disorder of ideation;" "double consciousness;" "the past and present confounded;" "feeling silly;" "losing their senses;" "confusion in the head;" "uneasiness;" "irritability;" "mental incapacity;" "sick-giddiness;" "vertigo;" "determinations of blood to the head;" "threatened apoplexy;" "tumultuary disorder," etc., are a few of the hundreds of expressions that might be gathered in the literature. The description given by Crichton (Vol. I, p. 237) of the case of Dr. Spalding of Berlin is most suggestive. When the patient tried to write he was unable either to think or to make sensible sentences. A multitude of excerpts might be gathered from literary history bearing witness to the same mental paralysis. Parkman's "stirred-up head" when he wrote a few minutes told him to stop; Wagner, Nietzsche, and indeed all eyestrain sufferers had the same or similar disorders.

But the profoundest evil is the dejection and disgust with life that follows persistent use of astigmatic eyes. It is noticed in all the best literature of migraine, ill humor, petulance, morbid introspection, irritability, proceed to melancholy and pessimism in the extreme cases. "Inexpressible fear" is recorded by Dr. Reynolds; "vague dread," "a sense of apprehension and insecurity," "dread," "apprehension," "something about to happen," "shuddering at the thought of an attack," "horror," are some of many expressions that have been recorded. Sir John Forbes says: "There seems to be some peculiarity in the pain, whatever be its degree, unlike the pains of other parts of the body, and as if it were combined with something of a mental quality. There is a feeling and a fear of impending death, and the primary symptoms of corporeal disorder, etc." This intellectual disorder and morbidity of the emotions is painfully evident in many great literary men who suffered from migraine or from eyestrain. In Parkman it was so evident, and yet so under control, that his friends, not himself, and the greatest physicians believed in his insanity. Wagner was also thought to be insane by physicians who knew nothing of migraine and less of eyestrain. Two of Nietzsche's oculists recognized the ocular origin of his malady, but that did not prevent the terrible tragedy of his paralysis. Even Professor Möbius, in 1903, says that "myopia can not produce migraine;" and this great clinician has not heard of astigmatism, or if he has heard of it, cares nothing for it. And if he cared much for it, he could not, in all Germany, get it corrected in his patients. Wagner resolved to commit suicide many times, when driven to desperation by his awful suffering. The effect of this mental torture and gloom in great literary workers is the almost single cause of the "literary pessimism" in an age of rugged vigor, luxury and national expansion.

The lessening of the amount of literary work that would otherwise have been done is exactly in proportion to the severity of the reflexes, or in the skill whereby they are avoided. In private practice one finds whole lives made futile, painful and invalid. Doctors are consulted, travel undertaken, spas visited, hydropathy pursued, quackery multiplied, patent medicines guzzled, narcomania encouraged, alcoholism made chronic. In biography one sees literary labor avoided, made impossible, reduced to an hour or two a day or to a life average of production of a few lines a day. To avoid this Parkman is compelled to write his own name by means of his gridiron, and Nietzsche is paralyzed at 44. Moreover, the literary work done is abnormal in character and is produced "in a white heat," the "nerves ablaze," in "a shivering precipitancy," etc., as Wagner, Nietzsche, Carlyle and others testify.

*Treatment.*—The chapters on the treatment of migraine are longer than that famous one concerning snakes in Ireland, but are less convincing and satisfactory. The systematic books and articles give pages of drugs to be tried. The profession at one time settled down to hydropathy and diet, until the amusing and yet warning resultlessness lessened the enthusiasm. And then the quacks took up these scientific methods. How both treated the 14 sufferers of "Biographic Clinics" may be read in those volumes. The present-day treatment of such patients is as ineffective and scarcely less irrational than in the time of Parr, who advises:

1. Keep the bowels open, i. e., give cathartics, purges, etc.
2. Drain from the head, by a perpetual blister on vertex, etc.
3. Emetics. "The tyro, without a suspicion of the difficulty, by the exhibition of an emetic has succeeded."
4. The fetid gums, especially if "joined with aloes."
5. Camphor, nitre.
6. He advises against the too common practice of cutting off the hair, because it is supposed to keep the head warm, and also in order that cold applications may be more conveniently applied. The author himself says that he long had headaches and that they returned frequently after shaving the head, and after he let the hair grow he suffered less in violence, frequency and duration of his paroxysms. (When Parr published his dictionary he was 59 years old!)
7. Bleedings, leeches, cupping-glasses, opening the temporal artery, diet, etc.
8. The suppression of the hemorrhoidal discharge. Parr doesn't believe much in this, but says that "in the whole circle of practical medicine no question is so difficultly explained as the connection of the hemorrhoidal discharge with the general health; or, rather, the supposed connection as stated by the German physicians. The experience of ages must not be overlooked. The hemorrhoids were considered at a certain period of life as essential to the male as the catamenia to the female."
9. Mental causes, anxiety, etc., are to be lessened.

*Sequels of Migraine.*—Martin and others have noticed that migraine often ends in a period of herpetism.

One is reminded of Wagner's life-long and inexplicable attacks of "erysipelas." Blanching of the hair has been noticed. The disappearance of migraine, says the "Dictionnaire des Sciences Médicales," is often followed by gout, asthma, hemorrhoids and cutaneous affections. Trousseau says the same of gout. Tissot, Wepfer, Schobelt, Laurent, Percy, etc., cite cases in which migraine disappeared and was at once replaced by an unconquerable diarrhea, to which the original disease was preferred. The relation to hemorrhoids noticed by Parr gives a glimpse into clinical medicine, at least of the middle and later ages, which seems to have been overlooked or outlived in our time.

*Use of the Eyes at Near-range is the Cause of Migraine.*—I have never had or read of a case of migraine or of sickheadache in which it was not strikingly manifest that near-use of the eyes was the cause of the disease. Fifty pages of quotations from Nietzsche, Wagner, George Eliot, etc., could easily be gathered testifying with amazing unanimity and intensity to this fact.[4] The records of private cases show the same thing. In the extreme cases, and especially during the ages from 40 to 60 years, this inability to write and read reaches such a height that it is possible only for an hour or two or a few minutes a day, and then only with cries of pain. Letters are replaced by postal cards, near-work with the eyes is renounced, and a trip is taken, wet-packs endured, walking or mountain climbing begun, etc. To such a degree was this recognized, both by patient and physician, that it became in the last few centuries an established practice to spend most of one's time in "walking the moors," journeys to Switzerland or Italy, trips to the seashore, etc. "A change of climate" became the universal prescription for all "brain-workers" who had symptoms of "brain-fag" or of "migraine." The great vogue of hydropathy arose largely from the suffering that followed near-use of the eyes, and spas, cures, mineral springs, health resorts of a hundred kinds and in a hundred places sprang up largely to meet the demand for ocular rest and the relief of other ills that came with it.[5] The world and the profession ascribed the cures to the stopping of intellectual work, and to the waters, packs, mountains and sunshine. But the ills returned always when the eyes were used. Thousands of other persons used brain and eyes without these ills, that made no difference in faulty observation, and the domination of theory and preconception.

Almost all observers find it impossible to draw any distinction between headache and megrim. What causes one causes the other. What cures one cures the other. As a matter of theory, they draw fine and infinite distinctions between the two, but they are terribly puzzled, contradictory and self-contradictory when it comes to observation of cases and to treatment.[6] The lighter forms of migraine, the unclassifiable thousand types of headaches and "masked migraine" are, says a later writer, "essentially of the same stock—merely feebly developed forms or the vanishing inheritance of previous generations." To such a pass have the theorists come! Driven by desperation and a sound observational instinct, the excellent Liveing, after excluding certain types, justly and rightly, crowds them all into "one independent affection, constituting a malady *per se*—all varieties of migraine."

Liveing is right in finding the riotous multiplicity of symptoms classed under headache, sickheadache, etc., to be the expression of one independent morbidity or malady *per se*, erroneously called migraine or the megrims. But Liveing, as well as every other writer on the subject (except Martin), missed the open secret. The appalling mystery of thousands of years, especially of the last 300, the explanation of the one disease whose cause and nature and cure are unknown, is now clear to all who wish to know, and whose minds are capable of receiving the truth. Migraine, in its so-called typical or in its multitude of atypical forms, is but one of the manifestations and results of eyestrain. Eyestrain produces almost an infinity of morbid results, and migraine, typical or not, is, if not absolutely, almost always, one of the products of the malfunction of astigmatic eyes. Any one can test the theory who wishes. The disease may be caused experimentally (on the skeptics, if they will!) by wrong glasses or by maladjusted right glasses. It may be cured by lenses correcting the astigmatism on which the disease depends.[7] The profession has for many years scorned the truth, until now the patients themselves are fast becoming aware of it without the doctor's advice. For many years to come they will probably have to teach physicians the etiology and therapeutics of their ailment.

---

[4] The cephalalgia of students, says Parr, is often a nervous affection merely. "Whatever be the action of the nervous fibers in intellectual operations its excess is often a cause of pain; though, in many instances, the cephalalgia of students is connected with obstruction of the bowels, and very often with increased determination to the head."

[5] This cause has been operative, one may believe, in establishing the English custom of country houses and homes.

[6] An old astute observer wrote: "It may be doubted whether causes do not sometimes produce pain in the head, which are still less easily traced. . . . On a review of these causes of idiopathic headache we must regret that the source of so few cases is discoverable and that we have scarcely appropriate remedies for any of those which we can ascertain."

[7] Very rarely it is not curable, as in the cases of George Eliot and Lewes, because a life of suffering has killed all reaction even when the cause is extinguished. In the young it is always curable—if the careful and scientific oculist is found.

# LIPOMA ARBORESCENS TUBERCULOSUM OF THE KNEE JOINT.

CHARLES G. LEVISON, M.D.

Associate Professor of Surgery in the Post-Graduate Department, University of California; Visiting Surgeon to the City and County and the Mount Zion Hospitals; Consulting Surgeon to the California Eye and Ear Hospital.

SAN FRANCISCO.

J. S., male, age 50, has suffered with a swollen knee joint for several years; this has gradually grown worse, and was extremely painful on motion. He was incapacitated for work, and was compelled to rest heavily on his cane while walking. There was no history of traumatism, syphilis or tuberculosis.

*Examination* revealed a knee much larger than its companion, with an obliteration of the patellar folds. Fluctuation was present. The patella was very movable, due to the presence of fluid within the joint; no pain on manipulation. The patient could flex his leg to a right angle; this movement was accompanied by a "meaty" crepitus, not the form of crepitation, however, commonly felt in a diseased joint; in other words, a sensation was transmitted on palpation, as if some soft substance were present within the joint. This crepitation became more marked as the flexion increased. The skiagraph revealed a shadow darker on the outer side. There was no increase in the number of leucocytes and no temperature.

*The Diagnosis* of hydrops tuberculosis with synovial involvement was made.

*Operation.*—Under hemostasis, an incision was made along the outer side of the patella, which was followed by the escape of about 120 c.c. of a clear yellowish serum. As this serum escaped, myriads of villi protruded into the wound; these, on closer examination, were seen to spring from the postpatellar bursa. On the outer side, the bursa of the quadriceps, which formed the basement membrane of these villi, was easily extirpated, but it was soon seen that, in order to remove the growth completely, it would be necessary to expose the entire joint. This was done by making a transverse incision through the extensor muscle, severing it completely from the patella, which was then turned downward and forward. Considerable difficulty was experienced in separating the bursa on the inner side from its attachment to the patella and the condyloid surfaces of the femur; these, however, were found free from disease. Hemorrhage was slight and easily controlled by pressure. The ends of the severed muscle were then united with plain catgut and the wound closed, small gauze drainage. A plaster cast was used with the leg in extension, no counter extension.

*Course.*—Recovery was uneventful, the patient leaving his bed within a fortnight. At this time passive motion was commenced, so that after four weeks he had 60 degrees of flexion. He then passed from my observation, being compelled to leave the city. Six months have now elapsed, and he writes me that he walks without a cane, using one only when walking long distances. He can bend his leg to a right angle, and is much pleased with the result of the operation.

For the following description of the above tumor, I am indebted to Dr. Lois Nelson, pathologist of the California Women's Hospital:

*Macroscopic Examination.*—The tumor is an irregular mass measuring 15 by 8 cm. and from 1.5 to 2 cm. in thickness, and represents the true synovial bursa. The outer surface of the tumor is comparatively smooth. The inner surface is thickly covered with villi, which produce a shaggy appearance. Each villus has a smooth surface, most of these being pear-shape and attached to the base of the tumor by very slender stems. The villi vary much in size; some are 2.5 cm. in length, and are broad, and others are pin point in size and thread like.

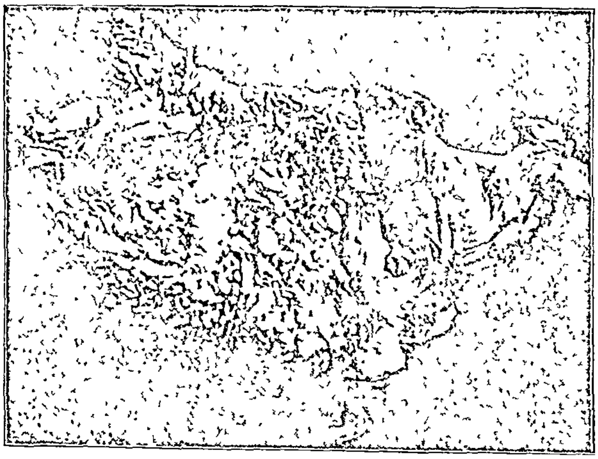
*Microscopic Examination.*—The base of the tumor is composed chiefly of fatty tissue, and projecting from this are innumerable villi of various sizes. Throughout this fatty tissue are scattered small areas of fibrous connective tissue, and very numerous groups of round cells. A few of these groups of small round cells show a typical arrangement of giant and epitheloid cells in the center and a border of lymphoid cells. The larger villi are composed of fatty tissue, with irregular areas of lymphoid cells, richly supplied with blood vessels, and an outer layer of connective tissue cells. Many of the smaller villi show very little or no fatty tissue, being composed chiefly of lymphoid cells surrounded by connective tissue cells. Several sections were stained for tubercle bacilli, but none was found. The specimen having been kept in formalin for several months prior to the examination would probably account for the failure to demonstrate the tubercle bacilli

*Diagnosis.*—Lipoma arborescens tuberculosum.

True lipomata of the knee joint have been observed. Riedel[1] reports two cases of this nature which were removed from the knee joint. They were both about the size of a walnut. In one of these cases the tumor sprang from the anterior surface of the femur, the other from the lateral surface of the patellar ligament. Koenig[2] explains the etiology of this condition, stating that in consequence of an overextension of the leg the sudden stain thrown on the fascia lateral to the patella would result in a tear of the synovial membrane, thus permitting the entrance of the extra articular fat into the joint. Here the nucleus for the development of a neoplasm is formed. If this be the correct etiology, this condition can hardly be classified with the new growths. In the "lipoma arborescens," as first described by Johannes Mueller,[3] a case is reported, characterized by the development of innumerable villi, which have undergone a fatty transformation, the process being considered a true lipomatosis of hypertrophic synovial villi. Schmolck[4] speaks of this condition as a "Lipomasie der Gelenk Zotten."

In consequence of impaired nutrition and diminished circulation, this process may become infected with the bacillus of tuberculosis, when there develops the "lipoma arborescens tuberculosum." This condition has been exhaustively described by Schmolck, who reports two cases of this disease, presenting excellent illustrations. In these cases, as well as the cases subsequently reported by Israel,[5] Von Brun,[6] Stieda[7] and Painter,[8] the true pathologic nature of the growth has been described.

The first case reported by Schmolck consisted of a tumor of the knee joint, and was composed of numerous villi of various shapes and sizes, several of them attaining the size of the thumb. On the surface of these villi minute tubercles could be seen macroscopically. The microscopic picture was that of tuberculosis. The *Bacillus tuberculosis* could also be demonstrated. In this case the joint contained no fluid, but in the second case considerable fluid was found. In the latter case the villi were not so large, but were of the same character.



Stieda reports two cases of his own, and reviews the literature quite exhaustively. His conclusions are reported in detail by Painter.[8] The latter reports seven cases of lipoma arborescens operated on by himself, with gratifying results. His conclusions are, in the main, in accord with those expressed by Stieda, but he believes tuberculosis to occupy a less prominent place in the etiology of this condition than does Stieda. Painter advocates the early opening of the joint, when the absence of clinical evidence of joint disease leads to the diagnosis of non-tubercular affection.

## IMPROVED TECHNIC FOR NERVE TISSUE EXAMINATION.

The invention of a new technical method is often of the greatest importance for the advancement of our knowledge of the minute structure of the human and animal body, for a method once devised by a single investigator may be applied by hundreds of others to the solving of special problems. So important is the extension of technic that a number of the ablest investigators, among whom as especially noteworthy Carl Weigert of Frankfort may be mentioned, devote nearly all their time and energies to this phase of science.

Particularly in the study of the structure of the nervous system is the influence of the introduction of special methods easily discernible. As a matter of fact, most of our newer knowledge of neural anatomy can be grouped around the methods of Flechsig, of Weigert, of Marchi, of Golgi, of Nissl and the methods of Apathy and Bethe. Especially fruitful was the modification of the Golgi method, devised some fifteen years or more ago by the distinguished Spanish investigator, Ramon y Cajal. His "rapid process" applied to embryonic tissues and the nervous systems of the newly born, revolutionized our ideas of the structure of the central and peripheral nerve organs and gave to the study of the histology of the nervous system an impetus so great that it is still felt in all quarters of the globe.

This autumn Ramon y Cajal has published the details[1] of another method applicable to the study of the nerve tissues, but this time not for the demonstration of the external morphology of the nerve cells and fibers, but for revealing those extremely delicate intraprotoplasmic structures, the neurofibrils of Apathy and Bethe. The methods for studying these fibrils employed hitherto—those of Apathy, Bethe, Simarro and Donaggio—have all been exceedingly unsatisfactory, owing to either inconstancy of result, complication of technic or limitation of applicability to single portions of the nervous system or to the neural tissues of only certain of the animal series. The new method of Ramon y Cajal does away with all these difficulties. It yields constant results, is simple, and is equally applicable to the tissues of man and animals down even to invertebrate forms. Moreover, it stains the neurofibrils from the time of their first appearance onward, so that we now have the means of determining both the histogenesis and phylogeny of these remarkably attenuated structures which exist within the protoplasm of the nerve cells. The details of the method are given in the article referred to. Suffice it here to say briefly, that it consists of impregnation with silver nitrate and subsequent reduction with a solution of pyrogallic acid.

One of our contributors, recently in Madrid, visited Ramon y Cajal's laboratory, and was shown the neurofibrils stained in a whole series of nerve-cell preparations of the most varied origin. The single threads stand out distinctly, stained dark brown coffee or chocolate color. Two kinds of neurofibrils can be made out: 1. Large primary fibrils which pass from one dendrite into another. 2. Small, pale granular secondary fibrils which anastomose with the primary fibrils and give rise to a complicated intraprotoplasmic network.

The significance of the neurofibrils is as yet entirely obscure. Apathy and Bethe regard them as the conducting elements of the nerve-cell protoplasm, but the evidence in favor of such a view is far from convincing; indeed, many of the best authorities regard the theory that the intraprotoplasmic fibrils conduct, as improbable. Further studies of these interesting features of the nerve cell will be awaited with interest.

---

## OYSTERS AND TYPHOID FEVER.

The towns known as "The Oranges" in New Jersey have been suffering from more typhoid fever than usual this year, and a recent increased prevalence of the disease led to a careful investigation by the health board of the city of Orange. As is usually assumed, this increase was at first attributed to the water supply. Careful bacteriologic investigation, however, failed to confirm the suspicion of possible sewage contaminations of the drinking water of the town. It was found, however, on investigation, that a number of the patients suffering from typhoid fever had been hearty eaters of raw oysters, especially in the period shortly before their fever manifested itself. The local health officer declares that "careful investigation has confirmed us in the belief that the present outbreak of typhoid fever has resulted from the consumption of oysters procured from infected beds."

This is, of course, not the first time that such an origin of typhoid fever has been suggested, but it should recall attention to the present methods of marketing oysters. Unfortunately many people seem to regard the plump white oysters, so often served now in restaurants, as preferable to the grayish, rather thin oysters that the gourmet of a few years ago was accustomed to consider the luscious delicacy best suited to his taste. Because of this false taste, oysters are bleached and rendered plump by dealers on the way to local markets. Normally oysters are accustomed to sea water. If they are removed therefrom and placed in fresh water for a time, they become much whiter than before and apparently grow fat. This plumpness, however, is not due to any addition of substantial material to the oysters' tissues, but only to the retention of more water than under natural circumstances. In a word, it is a question not of digestion of food and consequent accumulation, but rather a freak of osmosis. In order to secure this specious appearance of plumpness, oysters are not infrequently placed in fresh-water streams for a time before being served. Needless to say, with the present increase of population in this country, there are very few fresh-water streams that are not subject to contamination by sewage. Owing to the fact that oysters gather their food from water that flows by them, they are sure to retain any organic particles present, and typhoid bacilli thus find not only lodgment but a favorable culture medium in the oyster tissues. The fresh water apparently renders digestive processes in the oysters so sluggish that bacilli thus retained are not digested, as would be the case under normal conditions of life, but, on the contrary, actually increase in numbers, leaving the host still more incapable of resisting invasion.

---

[1] Ramon y Cajal S., Sobre un Sencillo Proceder de Impregnacion de las Fibrillas Interiores del Protoplasma Nerviosa. Arch. Latinos de Med., y de Biol., vol. i, 1903, Mudrid.

It would, therefore, seem rather important that, first, the present mistaken taste for bleached, plump oysters, which any connoisseur well knows are by no means equal to the thinner, grayish oyster fresh from the sea water, should be corrected; second, the present habit of dealers in supplying this false taste of their patrons should be officially discouraged, if not actually forbidden. Those who feel they must indulge in the luxury of uncooked oysters should be careful to know the source of the bivalves supplied them, and especially whether the bleaching, fattening process has been carried out in water that is above suspicion. These precautions are even more important in the inland towns at a distance from the seacoast than near the fishing beds of the oyster, because when oysters are shipped to some distance they take on an even flabbier appearance than normal, and dealers are tempted to improve their looks by the often dangerous process of immersion in fresh water.

---

## DOES IT PAY TO BE A DOCTOR?

From the heart of one who loves his fellow-men comes the latest tribute to the life of the real physician. Calm and dispassionate, but with a keen appreciation of the noblest ideals which we ourselves are so fond of holding up, Arthur Goodrich, in *Frank Leslie's Popular Monthly* for February, discusses: "Does It Pay to be a Doctor?" It will please every physician—even those for whom a veiled shaft is drawn—for it is so sensible. The following is worth quoting:

> The renowned physician started to study his profession late in life. He worked to make himself most helpful in his private practice, then to hospital patients, and finally as a professor to the young men who were beginning the long, uphill journey he had made. He has worked as nearly all of the so-called "big men" have worked, with philanthropic intent. He has an income of, perhaps, $60,000. The second man started work early: he has done a great deal of good, but his eye has been constantly reflecting the glitter of golden profit. He has an income of about $4,000.
>
> This, then, is the rock—the rock of money madness—on which the profession splits into professional doctors, merchant doctors and quacks. Of these the profession recognizes only the first, and draws rigid lines against the other two. Among reputable physicians there are, of course, many who have as acute an itch for money as a Wall Street broker—the doctor who said "charge big fees" is a reputable practitioner in the profession—but every doctor is a member of a vigilance committee against commercial methods, and the hand of the profession, through the county medical societies and other organizations, holds the men in line. Every doctor knows that once a man is cast out it is almost impossible for him to regain his standing in the profession, the standing he has worked years and spent thousands of dollars to obtain.

The commercial physician, the quack and the patent-medicine parasite are all valued at their true worth, and the author apparently draws the line from experience, such as the writer ought to have who essays to write such an article. While most of the statements in the article are correct, it is an overstatement to say that there are 200,000 physicians in the country. The overcrowded condition, bad enough as it is, is not so bad as that.

Mr. Goodrich calls attention to the required four years of academic work, four years more of grinding work in a medical college, two years of practical experience in a hospital, and then the sitting down to wait—for the physician can not go out after patients. Then there is the building up of a practice, slowly and by reason of worth and personality, while he fills in his odd time by perfecting his knowledge. After the practice is acquired, the average physician has only an income of $750. Large financial awards come to few men in the practice of medicine. Large fees, though justified, are frowned on by an inconsistent public, and the safeguards which the medical profession itself has erected to wall off commercialism holds the physician back from competence—to say nothing of a comfortable income.

Thus Mr. Goodrich answers the question from one viewpoint, but from another he paints the beautiful portrait of a true physician. "Anyone who sees a physician's work at close range knows that he spends hours of conscientious labor for which he never means to get money returns. The dispensaries and hospitals are filled constantly with sick who can not pay, and be it said, to the shame of the public, with sick who can pay as well." In every other profession general publicity is looked on as legitimate, but for the physician any kind of personal publicity is looked on askance by the profession. The profession looks on its work as private with its patients. Physicians publish valuable results for other physicians to use. "Hundreds of physicians and surgeons are constantly doing things that are really great and the public has never heard of them and probably never will, but the profession knows and respects them." The editor says in an introductory paragraph:

> There is no group of men of like importance in this country whose pictures and personalities are so unfamiliar to the public as those of our distinguished physicians and surgeons. The fact is a striking commentary on the unique conservatism

which has marked a single profession apart in our commercial age.

The two closing paragraphs are as follows:

> There are, however, other rewards, not for the doctor who plays politics or who uses "judicious advertising" without being caught, but for the conscientious, earnest man, "what amplest recompense!" Saving lives by quiet heroism, healing the sick, lengthening and lightening the days of many a chronic sufferer, daily deeds of kindness and charity, constant self-sacrificing service; these form a heritage that money can scarcely measure. An old and successful business man, after a conversation with a poor country doctor whom he knew as a boy, remarked with a tremble in his voice, that cried sincerity: "I'd give all I've got for that man's memories."
>
> Did you ever see a surgeon at work and feel the calm with which he unostentatiously does wonderful and dramatic things? Have you ever met a good doctor of experience and failed to feel his usually quiet, dignified, forceful personality, with the sentimental edges knocked off by rugged experience, but with sympathies, quickened and chastened by suffering? He is certainly different from the everyday *man with whom you* do business. Is it true that he is a dying relic of an "old school," or is he one of the bands between the old and a more vital future which will have in it the vigor and progressiveness of the present day, ripened and mellowed with old-time gentleness and charity?

## INHERITED TUBERCULOSIS.

The old notion of the direct heredity of consumption has been very generally treated as exploded since the discovery of the bacillus by Koch, and it is almost a point of faith at the present time to deny anything more than the remotest possibility of such heredity. The most that is usually admitted is that predisposition may exist, but that this may be counteracted by environment and proper treatment. Certain clinical facts, however, have still led some persons to maintain that the danger from communicable disease is on the whole less serious than from consumptive ancestors, whether the germs were transmitted directly or not. Thus, in an article published in The Journal[1] on conjugal tuberculosis, Bannister came to the conclusion that it was far more dangerous to have a consumptive parent than a consumptive wife or husband. Constitutional predisposition was credited in these cases, not the transmission of the germ. The latter, though known to be possible, was considered to be one of the rarest of happenings.

In a recent article,[2] however, Warthin and Cowie bring out certain facts which seem to point to the possibility of the direct transmission of the disease from parent to child, and that it may be of much more frequent occurrence than has been of late years suspected. After a careful study of the reported case and a detailed report of the postmortem findings, they conclude that placental tuberculosis is by no means only a rare possibility. In their case there was a general miliary tuberculosis of the mother with abortion and death at the fifth month, tuberculous thrombosis of the placental sinuses and intervillous spaces, tuberculosis of the placenta, tuberculous thrombi in the fetal blood and the presence of free tubercle bacilli in the fetal circulation without histologic change. They point out that the presence of tubercle bacilli in the maternal sinuses and in the intravillous spaces is a point of great significance, and that if the germs gain access to the circulation they will naturally tend to collect in the placental sinuses, there to give rise to pathologic disturbance. If their occurrence is possible in such great numbers, as in this case of miliary tuberculosis, is it not also probable, they ask, that, in cases of chronic or local maternal tuberculosis in which bacilli pass into the general circulation, the germs may collect in like situations and their future development depend on their ability to multiply? It may be perhaps assumed that the germicidal action of the blood will suffice to inhibit or destroy small numbers. If multiplication, however, does take place and agglutination and coagulation of the blood result, it is probable that these processes serve, within certain limits, to protect the placental tissue, but the authors referred to do not consider it safe to say that an intact syncytium will not permit the passage of bacteria. This, however, is not of such great importance if a denuded surface will permit the passage of bacteria. From its earliest period the chorion shows progressive atrophy and growth. Anemic infarcts are constantly present, and through such damaged areas bacillary transmission may occur. In the later months of pregnancy the placenta is a senile organ with many vulnerable points and many opportunities for the passage of germs. The fact that the bacillus may be present in such numbers in the fetal circulation without causing changes other than those of thrombosis is noted as apparently remarkable, and several theories are suggested to account for it. There may have been a very recent passage of bacilli through the placenta, or diminished virulence may be assumed or relative or absolute immunity on the part of the fetal tissues. The second possibility may be thrown out, as the germs showed full virulence in inoculation experiments. The question of immunity of fetal tissues will have to be settled by further investigations, but Warthin and Cowie think, if it can be proved that such an immunity exists and that tubercle bacilli may live for some time in the fetal tissues without causing histologic changes, the theory of latent congenital tuberculosis will receive a tremendous impulse. There are certain reasons for suspecting that such latency may exist, and cases have been reported, such as one referred to, by Doleris and Bourges, in which such a latency of tuberculosis seemed very probable. The apparent immunity, moreover, of the fetal tissues to certain poisons is well known.

Latent congenital tuberculosis, therefore, they conclude, is both possible and probable, and it is not unlikely that it is of much more common occurrence than is usually supposed. If we accept these facts and the deductions of the authors, it would seem that we shall have to revise one of the commonly accepted notions at the present time, namely, that of the rarity of transmitted

---

2. Journal of Infectious Diseases, January 2.

congenital tuberculosis. At all events, the paper is one that should leave an open mind in regard to the subject for future investigations to satisfy more or less thoroughly. There is evidently a need of further study, and perhaps one more disputable point has been added to the many that now exist in regard to tuberculosis.

## THE PRICE OF DIPHTHERIA ANTITOXIN.

Newspapers have had much to say, in the past few days, in regard to an antitoxin trust and the rise in price of antidiphtheritic serum. Much of what has been published has been of the sensational order, naturally. It is only fair that both sides of any question be considered before deciding pro or con, and with this in view THE JOURNAL has corresponded with three firms manufacturing this article, and has conferred with members of the Health Department of the City of Chicago, and with others interested.

It is denied by two of the firms that any combination of manufacturers of antitoxin has been formed, and it is asserted by all the firms that the price of the serum, "quality considered," is not higher, but lower than formerly. Until recently two grades of antidiphtheria serum have been on the market—a concentrated serum and a weaker one. The latter is no longer manufactured, and only the concentrated can be obtained, this being supplied in 1,000, 2,000, 3,000 and 4,000 units packages. Bulbs containing, respectively, 500 units and 1,500 units are no longer supplied. We quote below from the price lists of one firm, which are about the same as those of the others:

1903 PRICE LIST.

| Number of Units. | "X" Prices. | "XX" Prices. |
|---|---|---|
| 1,000 | $1.50 | $2.25 |
| 2,000 | 3.00 | 4.00 |
| 3,000 | 4.50 | 5.75 |
| [4,000 | Not listed | Not listed] |

Twenty per cent. discount to the retailer; 33 1/3 per cent. to the wholesaler.

1904 PRICE LIST.

| Number of Units. | List Price. |
|---|---|
| 1,000 | $2.00 |
| 2,000 | 3.50 |
| 3,000 | 5.00 |
| 4,000 | 6.50 |

Twenty-five per cent. discount to the retailer; 33 1/3 per cent. to the wholesaler.

It will be seen by comparing the price lists for the two years that there is an apparent small reduction in the price of the concentrated serum. We understand that the Health Department of the City of Chicago has been supplied in times past with the less concentrated or weaker serum, and this at a figure lower than that listed to wholesale druggists, the various manufacturers making bids for furnishing the serum. It is asserted that the Health Department has received such a discount that it only paid for 1,000 units, $0.57; for 2,000 units, $1.14; for 3,000 units, $1.71. If these figures are correct it is plain that the cost of the serum to the city will be twice that of last year, even with the same discount, because nothing but the concentrated serum can be obtained.

Now comes the question of the relative value of the two grades of serum formerly manufactured. Would 1,000 units of the weaker serum do the work of 1,000 units of the concentrated serum? Is the concentrated serum more reliable than the less concentrated, or is it merely more convenient as it is much less bulky? If the weaker serum is unreliable, it is well that it is no longer on the market, but if it has been found satisfactory, then its removal from the market forces the use of the more expensive serum, simply because concentration makes it more convenient to administer. Is it possible that the Health Department in previous years has been supplied with an inferior grade of serum in order to meet competition prices? We hardly like to think so. On the contrary, we understand that the serum used by that department has been perfectly reliable and satisfactory.

Can it be that, even at the low figure of 57 cents per 1,000 units, that the manufacturers realized a marginal profit, or are we to believe that the firms supplying the city with antitoxin have been doing charity work? Possibly the opportunity to advertise their goods was an inducement to make the special discount of some 62 per cent., whereas even the wholesalers are reported to have had only 33 1/3 per cent.

With the variable scale of discounts given in the past, we are inclined to infer that there must have been a large profit in the manufacture of antitoxin, especially when sold at the smallest discount, e. g., 20 per cent. to the retailer.

Judging from the correspondence before us and from the information which we have concerning the manufacture of antitoxin, we can not but believe that the prices of antitoxin have been and are higher than is necessary for a reasonable profit. We say this, realizing full well the great responsibility that rests on those who undertake to supply this most valuable therapeutic aid. Further, we can not believe that the firms supplying the Chicago Department of Health at over 60 per cent. discount from former prices were losing money.

Physicians are especially interested in this matter, not only because they want a city health department to secure the means of saving lives at a reasonable expense, but because they have the welfare of their patients at heart, many of whom, unable themselves to pay for antitoxin, are supplied at the physician's expense. But under no circumstances must it be thought that physicians want a cheap antitoxin; it must be good and reliable under all circumstances, no matter what the cost.

## FIRE RISKS IN COLLEGE AMPHITHEATERS.

These are the days of building inspection, revision of law, installation of fire-prevention devices and polishing rusty exit hinges. Shocked by the sacrifice of more than half a thousand lives in the Iroquois Theater fire in Chicago, the whole country is emphasizing that all buildings used for concourse shall be provided with adequate fire protection and means of escape. There is a class of buildings which has not, to our knowledge, been mentioned in the overhauling process now going on. In many medical colleges may be found amphitheaters on the third or fourth floor, seating, in some instances, hundreds of people, and lacking adequate means of exit. Many of these are in buildings whose interiors are wooden and of quick-burning construction, the stairways are few, narrow and winding, and the doors are small. On extraordinary occasions these amphitheaters are crowded to the limit, the halls below are deserted, and a fire under the right circumstances might cut off means of escape. An inspection of some of these buildings will reveal conditions alarming to those who have not heretofore viewed them with this possibility in mind. Because no terrible disaster has ever occurred is no reason that one may not occur. It would be well for those responsible for these buildings to, at least, take a look around and consider the possibilities.

### THE VALUE OF THE PHYSICIAN'S SERVICES.

The charge to be made for professional services will necessarily vary with a number of different conditions. This proposition is recognized in the practice of the law, and it should be equally so in that of medicine. Occasionally a judge on the bench may decide differently, but a moment's reflection will show the error of such a decision. There are to be taken into account especially the nature of the case, the character of the treatment to be pursued, the time consumed, the skill of the physician, and also the station—public and private—of the patient. The physician is, by force of circumstances, compelled to have a varying fee even for similar service. He can not elect to treat only the rich; neither can he afford to treat only the poor. He gives much of his service gratuitously, so that none is deprived of the opportunities for relief afforded by his skill and ability. For these reasons the physician's fee can not be a fixed and inflexible one. This would seem to be the view held by Judge Ashman of Philadelphia, as expressed recently in a decision rendered in the Orphans' Court: "The life of a rich man," he said, "is worth more than the life of a poor man, and the physician has a right to charge the millionaire more for his services than he does the laborer. . . . The physician is unlike the merchant, who has goods of different quality to sell at various prices. He must give his best service in every case. But it does not follow that the service is worth the same in every case. . . . Human life has a pecuniary value of variable quantity, greater in the millionaire than in the laborer. Thus, the practitioner of common sense has a maximum and a minimum charge and makes out his bills to suit the pecuniary circumstances of the patient."

### NEW YEAR CHANGES IN OUR FOREIGN EXCHANGES.

All our foreign exchanges show renewed vitality and improvement along various lines with the opening of the new year. The *Medizinskoe Obozryĕnie,* which Dr. Sprimon of Moscow has conducted so ably since he founded it thirty years ago, has been acquired by the Moscow Medical Society, but he will continue his editorial supervision. The *Presse Médicale* enters its eleventh year with several improvements, and the *Deutsche medicinishe Wochenschrift* has reorganized some of its departments and enlarged them all, as has also the *Münchener medicinische Wochenshrift.* The *Semaine Médicale* continues its serene course of restricting its size to twelve pages a week, and publishing only what it sifts out of the overwhelming material which each week offers. It still continues its remarkable practice of editorial abstracts of prominent articles published elsewhere, refraining from citing the authority. The series of letters from America is concluded. It has been as satisfactory as could be expected from a young and credulous physician traveling over a foreign land. The impressions derived from such a trip depend on the personal bias of the various natives the traveler happens to encounter, and their greater or less fondness for joking. The wonderful strides that have been made in the medical sciences in the last few years compel the ambitious physician to read about what is being done everywhere or he will soon be left hopelessly in the rear. Consequently the medical press everywhere feels this impetus and stimulus.

### THE PUBLIC PRESS COMMITTEE.

There is a function of the county medical society which is as yet not fully utilized, but which is sure to become more widely exercised when the machinery now being adjusted is in better working order. We refer to the "public press committee" of a society to contribute to newspapers articles unsigned as individuals, bearing on current medical and sanitary topics that will be of interest to the general public. The *Cleveland Medical Journal*[1] said recently: "The Newcastle County (Delaware) Medical Society has for some months had such a committee, which is doing excellent service to the profession and to the public." One needs only to glance at the average newspaper or popular journal to realize that there is a demand for this sort of information. Papers have columns headed "Talks with the Doctor," "Medical Items," "Department of Hygiene," etc., and it is certainly to be deplored that newspapers, in their inability to secure this information from reliable sources, have opened their columns to the advertising quack and to the man who is only a little "off color," but who is unwisely ready to furnish a medical article over his own signature. The fact that the articles are often full of errors and painfully exhibit a lack of education on the part of the author, only emphasizes the need of a public press committee. Instead of the antagonism which so often exists, there ought to be harmony and co-operation between the ethical physicians of a community and its newspapers. As rapidly as societies can arrange the matter, certain ones should be designated to perform this office, and it certainly will tend toward a greater harmony between physicians who shun publicity and newspapers whose business is publicity.

---

[1] November, 1903.

# Medical News.

## ILLINOIS.

**Physician's House Burned.**—The house of Dr. George T. Rowland, Martinsville, with all its contents, was recently burned.

**Smallpox at Sandoval.**—Public schools at Sandoval have been closed and general vaccination has been ordered on account of an epidemic of smallpox.

**Operation on Rockford Physician.**—Dr. Arthur F. Comings of Rockford was operated on January 14. The operation revealed pancreatitis, multiple abscesses of the pancreas and cholelithiasis. Dr. Comings rallied well after the operation.

### Chicago.

**Many Patients Treated.**—The annual report of the Hospital of St. Anthony of Padua shows that during the year 1,099 patients were treated.

**Will Rebuild Hospital.**—Michael Rees Hospital is to be rebuilt at a cost of more than $250,000. A special committee of the United Hebrew Charity Association has raised $145,000 of the amount.

**Chirography Expert Dead.**—Henry L. Tolman, noted as a microscopist, and an expert in handwriting, professor of medical jurisprudence in the University of Illinois Medical Department for many years, died at his home in Evanston, January 14, after a long illness, aged 55.

**Operation on Dr. Andrews.**—On January 16, Drs. E. Wyllys Andrews and Frank T. Andrews operated on their father, Dr. Edmund Andrews, for vesical calculus. The venerable patient rallied well from the operation, and is making satisfactory progress toward recovery.

**Must Muzzle Dogs.**—The city council passed an ordinance, January 18, on lines suggested by the Chicago Medical Society, providing that dogs must be muzzled all the year round, unless led by a chain. The fine for violation of this ordinance is to be not less than $2, nor more than $10.

**Deaths of the Week.**—During the week ended January 16, 566 deaths were reported, a mortality of 15.14 per 1,000 per annum. Pneumonia led with 117, followed by consumption with 64, heart disease with 50 and Bright's disease with 45. For the corresponding week of last year the death rate was 17.31 per 1,000.

**Inspection of Hospitals.**—Another and more rigid inspection of private hospitals, with special reference to their precautions against fire, was begun during the week. The last previous inspection, in the spring of 1902, was made by the building department alone. The one now being made is under the joint direction of that department and the department of health—a building inspector and a medical inspector working together in each investigation and making joint reports to each department. In this way it is hoped to secure better results in the matter of prompt remedy of defects discovered.

## MARYLAND.

**Smallpox.**—Dr. Otis B. Stone, Libertytown, is reported to have contracted varioloid from attending a smallpox patient.

**Registration of Nurses.**—A bill has been prepared by the Maryland State Society of Graduate Nurses to be introduced at the present meeting of the legislature, providing for state registration of nurses.

**Recommends Discontinuance of Appropriations.**—The Board of State Aid and Charities, in its report to the legislature, recommends that the appropriations to the medical schools be discontinued, also those to the Baltimore University Hospital, Franklin Square Hospital, attached to the Maryland Medical College, and the hospital of the Woman's Medical College.

**County Hospital and Pensions.**—At a meeting of the Washington County Medical Society, January 13, a committee was appointed to consider the advisability of establishing a county hospital. Another committee was appointed to frame a bill to be presented to the legislature for the reorganization of the outdoor pension system and medical care of the poor. It is proposed that all cases be investigated by inspectors as to their fitness to receive charity, and that physicians in each district shall attend the indigent sick at county expense.

**Report of Hospital.**—The report of Springfield Hospital for the Insane shows 509 patients there October 1. Of those discharged 28 had recovered, 10 were improved, and 1 escaped and was declared not insane by a jury. The percentage of cures to admissions was 21.05 of males and 16.43 of females. There were 20 deaths, 10 male and 10 female. Dr. Clark says there is a crying need for a hospital building for each sex for acute cases; also of an isolation ward, without which they are completely at the mercy of an epidemic. Tubercular cases are isolated in tents and epileptics in cottages. Insanity is greatly on the increase.

### Baltimore.

**Mortality from Lung Diseases.**—There were 228 deaths last week, pneumonia causing 38, consumption 31, and bronchitis 14.

**Bequests.**—The late John E. Hurst, millionaire merchant, left $30,000 to the United Charities Hospital at Cambridge, and $1,000 to the Church Home and Infirmary of Baltimore.

**Hebrew Hospital Report.**—Dr. Samuel L. Frank, president, reports 243 patients treated last year at the Hebrew Hospital, and in the dispensary thereof, 8,934. Legacies and donations were received amounting to $3,610.

**Election.**—At the annual meeting of the Baltimore Medical and Surgical Association, January 11, the following officers were elected: Dr. James M. Craighill, president; Drs. William B. Perry and John T. King, vice-presidents; Dr. Eugene L. Crutchfield, secretary; Dr. Nathan Winslow, treasurer; Drs. Edward L. Whitney, Joseph H. Branham and Martillus L. Todd, executive committee, and Drs. Wilmer Brinton, Daniel L. Dunnott, and Isaac R. Trimble, committee on honor.

**Personal.**—Dr. William H. Welch has been re-elected president of the State Board of Health.——Dr. William T. Howard celebrated his eighty-third birthday, January 12, by a dinner to his professional friends.——The supervisors of city charities have established a free medical agency in the northwestern section, with Dr. Henry M. Fitzhugh in charge and Dr. Katie De Sales Kelley, assistant.——Drs. H. M. Baxley, L. E. Beach and Edward E. Mackenzie have been elected physicians to the Baltimore General Dispensary.

**Statistics of Tuberculosis.**—The statistics of tuberculosis prepared for the exposition to be held January 25-31, show some interesting and startling facts. The death rate from tuberculosis per 10,000 of the population is 20 for whites and 40 for the colored race in Baltimore, and in the rest of the state 12 for whites and 29 for colored. One in every 10 deaths among the whites is due to consumption, and one in every 6 or 7 among the colored is due to the same cause. The following is the order of mortality from tuberculosis: District of Columbia, 30.52 per 10,000 population; Rhode Island, 19.53; New York, 19.41; Massachusetts, 18.62; New Jersey, 18.01; Maryland, 16.94; Connecticut, 16.83; Maine, 16.49; Vermont, 15.25; New Hampshire, 15.23. The exposition will open with a public meeting, January 25, and addresses by the governor, late governor, mayor, secretary of the State Board of Health, and president of the commission. Mr. Frederick Hoffman, secretary of the Prudential Life Insurance Company of Newark, N. J., will also speak on "Statistical Laws of Tuberculosis." A public meeting will be held daily at 5 p. m.

## MICHIGAN.

**Schools Closed.**—At Ovid, scarlet fever is so prevalent that it has become necessary to close the schools.

**Personal.**—Dr. Samuel Schultz has been appointed health officer of Coldwater, vice Dr. Daniel D. Cunningham, deceased.

**Smallpox.**—Osceola County has 28 persons in quarantine.——Marshall has 8 cases and individuals under surveillance.——In Covert there are 10 cases, and many families in quarantine.——A case is reported at Muskegon.

**Prevalence of Disease.**—Reports to the State Board of Health from representative general practitioners throughout the state show that the chief diseases in order of prevalence for December were as follows: Rheumatism, bronchitis, neuralgia, tonsillitis, influenza, nephritis, tuberculosis, pleurisy, pneumonia, typhoid fever, diarrhea and scarlet fever.

**Comparative Morbidity.**—For December, 1903, compared with the average for December in the last ten years, inflammation of kidney, typhoid fever, scarlet fever, smallpox, meningitis, and cholera infantum were more than usually prevalent, and diarrhea, erysipelas, intermittent fever, inflammation of bowels, measles, remittent fever, whooping cough, inflammation of brain, puerperal fever and cholera morbus were less than usually prevalent.

**The Most Dangerous Communicable Diseases.**—Meningitis was reported present in Michigan during December at 9 places, whooping cough at 19 places, measles at 62 places, smallpox at 90 places, diphtheria at 100 places, typhoid fever at 117 places, scarlet fever at 172 places and consumption at 201 places. Meningitis was reported present at 5 places more, whooping cough at 3 places more, measles 31 places more, smallpox 37 places more, typhoid fever at 37 places less, diphtheria at 20 places more, scarlet fever at 50 places more, and consumption at 8 places more than in the preceding month.

**December Mortality.**—There were 2,942 deaths returned to the department of state for December, or 319 more than reported for the previous month. The death rate was 14.1 per 1,000 population, as compared with 12.9 for November. There were 490 deaths of infants under 1 year, 191 deaths of children aged 1 to 4 years, and 944 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 191; typhoid fever, 48; diphtheria, 96; scarlet fever, 17; measles, 16; whooping cough, 23; pneumonia, 376; influenza, 49; cancer, 151; accidents and violence, 182. There was a decrease in the number of deaths reported from typhoid fever, and the usual seasonal increase in deaths from pneumonia and influenza. There were no deaths from smallpox during the month. One death from chicken-pox was reported.

## MINNESOTA.

**Quarantine Lifted.**—The Duluth Board of Health has issued orders allowing 23 children under quarantine for diphtheria or scarlet fever to resume attendance at school.

**Personal.**—Dr. Llewellyn D. Peck, health officer of Hastings, has been elected physician for Dakota County.——Dr. Harry W. Darby, Minneapolis, has sailed for Europe.

**Crusade Against Spitting.**—The campaign against spitters began in earnest in St. Paul, January 15. Spitters were forced by health officers to take out their handkerchiefs and mop the sidewalks they had befouled. On January 18 the inspectors began to arrest offenders. Health Commissioner Ohage is taking a wide interest in the campaign.

**Regulation of Tuberculosis.**—The assembly committee on streets has ordered a favorable report on Dr. E. H. Whitcomb's ordinance for the regulation and prevention of tuberculosis in St. Paul. Dr. H. M. Bracken, secretary of the State Board of Health, urged the adoption of the ordinance on the ground that under its provisions the city health department will be able to keep a record of tuberculosis cases, and to prevent infection by requiring vacated premises to be disinfected. The ordinance declares tuberculosis an infectious and communicable disease and requires reports to the health commissioner from physicians and managers of hospitals of all cases coming under their observation. In case a tuberculous patient vacates a residence, the owner of the premises is required to disinfect the same under direction of the health department. Should the owner fail to comply with this provision the health commissioner is directed, after 36 hours' notice, to placard the premises as unhealthful and unfit for occupancy.

## NEW JERSEY.

**Circus Aids Hospital.**—The amateur and professional circus in aid of St. Joseph's Hospital, Paterson, netted $1,500 to the institution.

**Anti-Vaccinationist Has Smallpox.**—Dr. Allen S. Ironside, Camden, prominent as an opponent of vaccination, is ill with smallpox, and is under quarantine at his home.

**Barker Memorial Unveiled.**—The memorial tablet to the late Dr. Phanett C. Barker was unveiled, January 11, at the Barker Pavilion for Contagious Diseases of the Memorial Hospital, Morristown.

**Want Health Board of Physicians.**—The Practitioners' Club of Jersey City announces that it is about to start a movement for a new board of health, composed entirely of physicians.——The Passaic Medical Society has passed resolutions asking the mayor-elect to appoint physicians as members of the board of health.

**Society Election.**—At the annual meeting of the Atlantic County Medical Society the following officers were elected: President, Dr. Theodore Senseman, Atlantic City; vice-president, Dr. Edmund A. Madden, Absecon; secretary-treasurer, Dr. Edward Guion; reporter, Dr. A. Burton Shimer; board of censors, Drs. Edward A. Reiley, Edwin H. Harvey, and William M. Pollard; delegates, Drs. Elisha C. Chew and J. C. Marshall, and alternates, Drs. Wait P. Conaway and M. LeRoy Somers, all of Atlantic City.

## NEW YORK.

**Bequest to Medical College.**—By the will of former congressman James J. Belden, Syracuse, $50,000 is devised to the College of Medicine of Syracuse University.

**Tuberculosis Pavilion at State Hospital.**—The State Lunacy Commission will erect a pavilion for the care of patients afflicted with tuberculosis on the grounds of the St. Lawrence State Hospital, Ogdensburgh. For that purpose $30,000 has been appropriated.

**Medical Society of the State of New York.**—The ninety-eighth annual meeting of this society will be held in Albany, January 26, 27 and 28. Especial interest is centered in this meeting, owing to the fact that final action is expected to be taken in the matter of the combination of the two state medical organizations.

**Personal.**—Dr. Donald L. Ross has resigned his position on the staff of the Willard State Hospital, and has accepted the position of first assistant physician at the Craig Colony, Sonyea.——Dr. Newell E. Landon, Newark, recently suffered severe injuries in a runaway accident.——Dr. J. Wilson Poucher has been appointed surgeon of the Fifteenth Separate Company, N. G., N. Y., Poughkeepsie, vice Dr. John A. Card, resigned.——Dr. H. Wardner Eggleston, of the staff of the Binghamton State Hospital, has been made first assistant physician, vice Dr. William A. White, resigned.

**The Smallpox Situation.**—The state health department has issued a bulletin showing that new cases of smallpox have appeared during the past week in the following places in the state; Salamanca and West Salamanca, Cattaraugus County; Plattsburg, Clinton County: Cambria, Niagara County, and Massena, St. Lawrence County. The epidemic which has prevailed extensively in the villages of Medina appears to have abated.——A case of smallpox has appeared at Wells College, Aurora, and the college has been quarantined.——At Lockport the places of public gatherings have been closed, even including a cessation of distribution of books by the public library. Fifteen actual or suspected cases have resulted in the sending to Lockport of the secretary of the state health department, Dr. W. E. Johnson, to assist the local authorities in combating the disease.

### *Buffalo.*

**Charity Ball a Success.**—The charity ball which was given for the benefit of the German Hospital was a pronounced success, and will net the hospital between $1,200 and $1,500.

**Smallpox.**—At the present time 16 cases have been reported in this city. They are located in the tenderloin districts, which makes it difficult for the health authorities to control. In one case smallpox was found in a waiter in a cheap restaurant, who was waiting on 200 persons.

**December Deaths.**—The monthly report of the department of health for December shows a death rate of 14.77 per 1,000. The principal causes of death were as follows: Consumption, 34; cerebrospinal meningitis, 7; diphtheria, 10; typhoid fever, 10; cancer, 22; apoplexy, 23; meningitis, 11; valvular disease of the heart, 23; bronchitis, 12; pneumonia, 53; nephritis, 26; diabetes, 7; violence, 42. The total deaths for the month were 468, as compared to 503 in December, 1902.

**Medical Society of the County of Erie.**—At the eighty-third annual meeting held in Buffalo, January 12, Dr. William C. Krauss was elected president; Dr. Franklin C. Gram, secretary, and Dr. Edward Clark, treasurer. The society condemned Mayor Knight's efforts to send all the sick poor to the County Hospital. Memorials for deceased members were presented as follows: Dr. Herman Mynter, by Dr. Henry R. Hopkins; Dr. Herbert Mickle, by Dr. W. Scott Renner; Dr. William H. Jackson, by Dr. Alvin A. Hubbell; Dr. Byron H. Daggett, by Dr. Nelson W. Wilson.

**Annual Death Rate.**—The annual report of the Bureau of Vital Statistics shows the average death rate for the year to have been 14.95 per 1,000. The total number of deaths for the year was 5,681. The death rate of 1902 was 13.70; for 1901 it was 14.68; for 1900, 14.19; for 1899, 12.59; for 1898, 12.25; for 1897, 12.42; for 1896, 12.72; for 1895, 13.95; for 1894, 16.76; for 1893, 19.03; for 1892, 19.98; for 1891, 23.47, and for 1881, 25.72. During the past year the month of greatest mortality was August, and the next highest month was July. There were 525 more deaths among males than among females.

**Personal.**—Dr. Floyd S. Crego, formerly chief surgeon of the Fourth Brigade, N. G., N. Y., gave a dinner at the Buffalo Club to the officers of the brigade on his retirement. Among the invited guests were Drs. Charles G. Stockton and Roswell Park.——Dr. Charles Vaux has been appointed junior assistant physician at the Manhattan State Hospital.——The officers elected for the German Hospital Dispensary were the following: President, Dr. Alois Jokl; vice-president, Dr. Charles Durand, and secretary-treasurer, Dr. Adolph Urban.——Dr. Henry D. Ingraham is ill and confined to his home.——Dr. Edward J. Meyer has gone south for his health.

**Morbidity and Mortality of 1903.**—During 1903 there were 351 cases of typhoid fever reported, with a mortality of 133. There were 471 deaths from consumption. The discovery of antitoxin has had a wonderful effect on the mortality from diphtheria; there were 794 cases reported, with 110 deaths. Of 465 cases of scarlet fever reported there were but 26 deaths. There were 533 cases of measles reported, with 37 deaths. With cholera infantum but one case was reported earlier than May. The month of greatest mortality was August. The dissemination of pamphlets instructing the mothers how to treat such cases has resulted in a marvelous decrease in the death rate. In 1901 the number of deaths was 186, in 1902 it was 141, and last year the number was still further reduced to 121.

**Would Send Sick Poor to County Hospital.**—Mayor Knight has drafted a bill to empower the overseer of the poor, a city official, to send poor cases to the County Hospital. At present the superintendent of the poor, a county official, is the only person clothed with such authority. During the fiscal year 1901 more than $50,000 was paid to private hospitals for city cases, and the year following the amount increased to $70,000. Mayor Knight believes that many of these cases should be sent to the County Hospital when the city pays 85 per cent. of the expenses of that institution. The city hospitals are protesting against the measure. There are six or eight hospitals in Buffalo to which ward patients may be sent on city orders, and where a sum must be contributed by public charities in excess of the per capita allowance of the city. It is said that many poor patients, rather than be stigmatized as paupers by being sent to the County Hospital, will not seek aid at all. The hospitals which Mayor Knight designates as private hospitals state that they are not such in fact, but are public hospitals, maintained by public charities, of which the city must bear its proper share.

### New York City.

**Spitters Arrested.**—On January 12 the police arrested ten persons for spitting in violation of the sanitary regulations. Of the defandants, 7 were fined $1 each, and 3 were discharged.

**New Hospital.**—Mrs. J. Hood Wright, widow of the founder of the J. Hood Wright Hospital, has announced that she contemplated building, at a cost of $2,000,000, a new hospital in memory of her husband, to take the place of the present one, which lies in a hollow.

**To Advise Board of Health.**—Former Health Commissioners Ernest J. Lederle and Charles F. Chandler have been appointed consulting sanitarians of the present board and will also sit as members of the advisory board. These positions are purely honorary, with no salary attached.

**Money for Hospitals.**—The German Hospital received $4,500, the net receipts of the benefit opera performances held in November last.——The Post-Graduate Hospital has been paid a legacy of $5,000, bequeathed by Mrs. Samuel Colman to endow a bed in the babies' wards of the hospital.

**Hospital Jubilee.**—The New York Infirmary for Women and Children, which was founded in 1853 by Dr. Elizabeth Blackwell, celebrated its fiftieth anniversary, January 16, at the Waldorf-Astoria. Dr. William H. Welch, Baltimore, and Miss M. Carey Thomas, president of Bryn Mawr College, were among the speakers.

**Need Ten-Million-Dollar Endowment.**—The annual reports of twenty hospitals in the city show a total deficit at the close of the fiscal year of $432,368.78. In the judgment of those who have studied this subject most carefully, it needs an endowment of not less than $10,000,000, securely invested, to yield the revenues required to make up the present annual deficit of the New York hospitals.

**Personal.**—Dr. Patrick J. Murray, the new health officer of Brooklyn, has reported for duty.——Dr. Russell Bellamy has been commissioned captain and assistant surgeon of Squadron "A," N. G., N. Y.——Dr. Ellen L. Lowell has been appointed chief bacteriologist at the Graves Pathological Laboratory of the Orange (N. J.) Memorial Hospital.——Dr. Arthur J. O'Leary has been appointed visiting physician to Manhattan College, vice Dr. Cornelius M. O'Leary, deceased.

**Wage War on Pneumonia.**—Vigorous measures to check the epidemic of pneumonia will promptly be taken by the health authorities as a result of a meeting held January 12 by Dr. Thomas Darlington, the new commissioner, and the members of the advisory board of the department. In the last five weeks of 1903 there were 889 deaths in Manhattan alone from this cause, as against 586 for the corresponding period of the previous year. Several methods of action were chosen as a beginning of the work. These include the cleaning of all public buildings, including school-houses, a rigid enforcement of the law requiring the cleaning of sidewalks from snow and slush, insisting on the proper heating and ventilation of street cars, surface and elevated, and the enforcement of the prohibition against expectoration on the sidewalks, or anywhere else where infection may be caused.

## PENNSYLVANIA.

**Typhoid at Kittanning.**—It is reported that there are now 100 cases of typhoid fever at Kittanning, and that the disease is spreading rapidly.

**Petition Denied.**—In the United States Circuit Court, January 4, Dr. Susan J. Tabor was refused a new trial in her suit against the Norristown State Hospital to recover $2,072.50 for salary alleged to be due her.

**Guilty on Two Counts.**—Dr. Robert H. Gilliford, Allegheny, charged by another physician of the city with felonious assault, carrying concealed weapons, and pointing firearms, was found guilty on the two latter counts, the jury recommending him to the extreme mercy of the court on the last count.

**Personal.**—Dr. Milton A. Robison, after 20 years of practice in Hazelton, retired from practice January 1.——Dr. Edward R. Myers, Pittston, has been appointed a resident physician of the Harrisburg Hospital, vice Dr. John A. Sherger, resigned.——Dr. Charles A. Arnold, Allegheny, was seriously burned in a natural gas explosion at his residence, December 31.——Dr. J. D. Kramer has succeeded Dr. Horace F. Taylor as resident physician at the Chester Hospital.

**Smallpox Closes Schools.**—By order of the State Board of Health all the schools in three townships, Morris, Center and Rich Hill, in Greene County, and two adjoining townships, East and West Finley, in Washington County, have been closed indefinitely on account of smallpox. An epidemic of smallpox is raging in the border townships. The authorities of Luzerne borough, frightened by an outbreak of smallpox there have issued orders that all schools, churches, dance halls, places of amusement and public places be closed for fifteen days, in the effort to prevent the disease spreading.

**The Butler Typhoid Epidemic.**—The epidemic of typhoid fever at Butler seems to have practically run its course. The census conducted under the auspices of the Pennsylvania State Board of Health was completed January 5, and showed that up to that date there had been 1,316 cases and 84 deaths. Deaths occurring in other towns attributable to infection in Butler bring the total number of deaths up to 95. The number of deaths from typhoid fever at Butler up to January 15 reached a total of 101. A very few new cases continue to be reported. The officials of the State Board of Health in charge of the local situation state that they have obtained information regarding the existence of no fewer than seventeen cases of typhoid fever on the watershed of the contaminated creek during the summer and fall of 1903. The relief committee has issued the statement that the funds now in hand are sufficient for the prospective needs and that no more outside assistance will be necessary; it has also expressed public thanks for the generous assistance rendered by physicians, nurses and the general public. The total amount of money received is between $50,000 and $55,000, and a surplus of about $10,000 still remains.

### Philadelphia.

**The New Municipal Hospital.**—Plans have been completed by the Department of Health for the heat and power plant of the new Municipal Hospital, to cost about $125,000. The buildings have been erected and partitioning into wards has begun.

**Bequests to Hospital and College.**—By the will of the late Henry B. Ashmead, a printer, his estate, valued at $500,000, reverts to the Episcopal Hospital, as a memorial to his widow, after her death and that of her daughter.——Louis C. Vanuxem, whose estate is valued at over a million dollars, bequeathed $25,000 each to Princeton University, of which he was an alumnus, and to Jefferson Medical College, of which he was a trustee.

**Death and Disease.**—For the week ended January 16, the deaths numbered 736, the highest death rate for any week in three years. Soft coal smoke, but especially slush and cold, are responsible for much sickness. Deaths from diseases of the respiratory passages, aside from phthisis, numbered 188. There was considerable decrease in the number of new cases of smallpox and typhoid fever, there being 58 of the former and 89 of the latter.

**Club Elects Officers.**—At the annual meeting of the Medical Club of Philadelphia, held January 15, the following officers were chosen: President, Dr. Edward E. Montgomery (re-elected); vice-presidents, Drs. Roland G. Curtin and Wharton Sinkler; secretary, Dr. J. Gurney Taylor; treasurer, Dr. F. Savary Pearce; member of the board of governors, to serve five years, Dr. Edward L. Duer, and additional members of the executive committee, Drs. Hobart A. Hare, Ernest Laplace, Alexander McAlister, Walter L. Pyle, and William H. Warder. The retiring secretary, Dr. Guy Hinsdale, who had served for the past five years, was given a loving cup. Dr. Hinsdale will go, February 1, to Hot Springs, Virginia, to practice.—The presentation was made on behalf of the club by Dr. T. Chalmers Fulton. The club has now a membership of 575 and encourages hospitality and good fellowship.

**Mortality and Morbidity of 1903.**—The annual report of the Bureau of Health for 1903 shows the death rate to have been 18.82 per 1,000 of population. This is higher than for 1902, the rate then being 17.67. The rate is the lowest, however, with three other exceptions since 1879. The total number of deaths for the year was 25,947, as compared with 23.847 for the previous year. There was a large increase in deaths from typhoid fever, there being 585 in 1902 and 957 last year. The greatest number of deaths from a single disease was from pneumonia, 3.180, as compared with 2,976 for the previous year. Tuberculosis deaths numbered 3,053, an increase of 208 cases over last year. Deaths from smallpox numbered 278, 47 more than in 1902. Cases of contagious diseases for the two years were as follows:

| | 1902. | 1903. |
|---|---|---|
| Scarlet fever.......... .. ...... | 3 161 | 3.200 |
| Diphtheria .................... | 2.444 | 3 043 |
| Typhoid fever.................. | 5.006 | 8.650 |
| Smallpox ...................... | 1,342 | 1,637 |

## TEXAS.

***New Secretary of State Association.***—Dr. John T. Moore, Galveston, has been appointed secretary of the Texas State Medical Association, to fill the unexpired term of Dr. H. A. West, who recently died.

## GENERAL.

**Medical Clerks Wanted.**—The United States Civil Service Commission will hold examinations, Feb. 17-18, 1904, in various prominent cities to fill eighteen vacancies in the position of copyist (male), at $900 per annum, in the Bureau of Pensions, and other similar vacancies as they may occur. The examination will consist of the following subjects:

1. Letter-writing (a letter of not less than 150 words on some subject of general interest. Competitors will be permitted to select one of two subjects given).
2. Penmanship (the handwriting of the competitor in the subject of copying will be considered with special reference to the elements of legibility, rapidity, neatness, general appearance, etc ).
3. Copying (a test consisting of two exercises—the first to be an exact copy of the matter given, and the second to be the writing of a smooth copy of rough draft manuscript, including correction of all errors of spelling, capitalization, syntax, etc.).
4. Anatomy and physiology.
5. Diagnosis.
6. General and special pathology.
7. Surgery and surgical pathology.

The age limit is 25 to 30 years, and only graduates of recognized medical schools will be examined. This examination is open to all citizens of the United States who comply with the requirements. Persons who desire to compete should at once apply, either to the United States Civil Service Commission, Washington, D. C., or to the secretary of any local board of civil service examiners, for application Form 1,312, which should be properly executed and filed with the commission at Washington.

## CANADA.

**The Typhoid Situation in Montreal.**—Several more cases of typhoid fever developed in Westmount, one of the suburbs of Montreal, during the past week, and in St. Henri, the situation continues very grave. There are still 30 cases in the Montreal General Hospital; at the Royal Victoria, 45 cases, and at the Hotel Dieu, 25.

**Checking Consumption in British Columbia.**—The board of health of this province has decided to take vigorous action on tuberculosis. British Columbia is said to be one of the very few civilized communities of the world which has done almost nothing in the way of prevention of tuberculosis. A circular has been prepared for general distribution, and it is understood that the Canadian Pacific Railway will give $25,000 for the project. A British Columbia association for the prevention and cure of tuberculosis will be formed.

**Ontario Vital Statistics.**—In the annual report of the registrar general for Ontario, which is now being prepared for 1903, the conditions prevailing are generally satisfactory. There were 47,796 births reported as compared with 46,061 for 1901, an increase of 1,735, giving a general rate of 21.7 per cent. The birth rate in the cities is 22.2, or 0.5 higher than the general average. The marriages in Ontario were 18,072, compared with 18,035 in 1901, an increase of 37. The average for the province is 8.2, but in the cities alone it is 12.2, and in the towns, 12.8. The effect of the elopements from Detroit is shown in the high rate of Essex County, which is 26.7. The total number of deaths was 27,864, as compared with 29,608, giving a rate of 12.6, compared with 13.6 for 1901. The high average of health in Ontario is shown by comparison with other countries. In the United Kingdom it is 17.1; in Norway, 14.9; Austria, 24.2; Switzerland, 18.0; German Empire, 20.7; Quebec, 19.9. In Toronto the rate is 15.4; in Hamilton, 14.6; in London, Ont., 15.2; in New York, 20.57. The details for 1902 show a remarkable decrease from contagious diseases, which were 1,944, as compared with 2,590 in 1901. The deaths from tuberculosis also show a continued decrease, having fallen from 127.8 in 1898 to 90.6 in 1902.

## FOREIGN.

**Physicians for the Russian Trains.**—The Russian authorities are planning to have a medical attendant on each of the through Siberian trains.

**Prize for Inventor of Infiltration Anesthesia.**—The Würzburg University has bestowed the Rinecker prize of a silver medal and sum of $250 on Prof. C. L. Schleich of Berlin, as a token of appreciation of his method of infiltration anesthesia. His first publication on the subject was in 1894, when he published "Painless Operations," which has passed through many editions since.

**Typhoid Bounty.**—The city council of the French city of Rouen has adopted the plan of offering a prize of $2 to the first person who notifies the authorities of a case of typhoid fever. A sum of $4 will likewise be paid to the family if they agree to follow the directions of the board of health in regard to disinfection, etc. When the city council adopted the above typhoid bounty plan the only two dissenting votes were those of the two physicians who serve as members of the council.

**French Climatotherapy Congress.**—A congress has been organized to meet at Nice, April 4 to 9, 1904. Professor Chantemesse has been appointed president and the executive committee also includes Rénaut of Lyons, Grasset of Montpellier, Calmette of Lille and Balestre of Nice. The general secretary is Dr. Hérard de Bessé, 5 Boulevard Central, Beaulieu-sur-mer, France. Addresses will be delivered on the "Climate of the French Mediterranean Coast," "Adaptation of the Individual to the Climate," "Influence of this Coast Climate on Tubercular Patients," "Influence on Rheumatism and Those Subject to Rheumatism," and on "Disinfection of Towns."

**Antimalaria Education of the Public.**—The two physicians who are the moving spirits in the "Ligue contre le Paludisme," founded last spring at Alger in Algeria, have issued a small pamphlet in which is described in popular style the recent acquisitions to our knowledge of the transmission of malaria by mosquitoes. They summarize the deductions in the two desiderata: "Prevent man from being bitten by contaminated mosquitoes," and "Prevent the anopheles from biting contaminated human beings." The various means by which this can be accomplished are portrayed by pictured and simple descriptions. In conclusion the pamphlet contains a few simple rules of general hygiene. The benefits of this plan of educating the public have already become apparent in this French colony.

## LONDON LETTER.

### Shellfish and Sewage.

Outbreaks of typhoid fever due to sewage-contaminated shellfish have recently been described in THE JOURNAL. The Royal Commission on Sewage Disposal, which has been inquiring into the subject for the last 3 years, has just issued a report. The commission has had little difficulty in concluding that shellfish contaminated by sewage may produce typhoid fever and other illnesses. Dr. Newsholme, health officer for Brighton, declared that 37 per cent. of the typhoid fever in that town from 1894 to 1902 were due to shellfish, and other health officers gave similar evidence for Manchester, Yarmouth and Southend. The commission recommends that tidal waters be placed under the jurisdiction of a competent authority empowered to prevent the taking of shellfish for consumption from any position in which they are liable to dangerous contamination and to enforce restrictions as regards waters, foreshores, pits, ponds, beds and layings in which shellfish are fattened or stored. New legislation will be necessary to prevent seaside towns discharging their sewage in such a way into the ocean as to pollute shellfish used for edible purposes.

### The Cooking of Shellfish.

Some experiments carried out by the Fishmongers' Company on the cooking of the smaller shellfish are of interest in connection with the scare raised by sewage-contaminated shellfish. Dr. Klein, bacteriologic adviser to the company, has proved that the usual method of cooking only amounts to scalding and can not be relied on to sterilize the fish. The live fish with shells tightly closed are held in a net and plunged into boiling water. The immersion of the cold mass lowers the temperature, and when, in two or three minutes, the water begins to boil again the net is lifted out. Fish that had been kept in typhoid-polluted water so treated were found to be swarming with typhoid bacilli. Prolonged boiling would no doubt be effective, but it spoils the fish for sale. Dr. Klein then suggested that cooking by steam, in consequence of its greater penetrative power, might be an efficient sterilizer and not spoil the fish as food. Two batches of cockles and mussels were cooked in a steamer for five and ten minutes. The results were: mussels spoilt and useless for sale; cockles all right in upper layers, but bottom layer overcooked. The mussels cooked for five minutes were all right, and the cockles better than the ten minutes' batch, but the bottom layer was somewhat overcooked. In all cases the cockles were sterile; the mussels were sterile except those on the top steamed for five minutes, some of which retained living spores. It is probable that if exposed to the more direct action of the steam the mussels could be completely sterilized in five minutes. As a result of these experiments the Fishmongers' Company has strongly recommended steaming to the trade.

## Correspondence.

### Opticians: An Appeal to the Medical Profession.

NEW YORK CITY, Jan. 16, 1904.

*To the Editor:*—An optical society, composed of so-called "refracting opticians," has issued a circular letter to the medical profession, asking for the endorsement of a bill about to be introduced in the legislature, legalizing the "practice of optometry."

This measure is not a new thing; we have met it several times in the past, and it has only been necessary to expose its pernicious features to defeat it. It will be necessary to do this again and again until the public awakens to the fact that measures such as this are only the efforts of incompetent people to evade the medical laws in order that they may prey on the community without fear of molestation, and then suitable provisions will be made to suppress them.

It is to be hoped that members of the medical profession will not be influenced by the specious arguments of these opticians to give them any encouragement or endorsement; for any success they may attain will be the signal for a host of osteopaths and other peculiar people to ask for similar privileges. There are no good reasons why opticians should be granted any special privileges. They undertake to do a work which they are not in any way qualified to undertake, and there is no doubt, in the minds of those who are competent to judge, that they do incalculable harm and injury. They, in common with all others who treat physical defects and infirmities, should have a medical education before they are allowed to go before the public as competent to do the work that they pretend to be able to do. It can not be expected that future physicians will be willing to undertake a course of studies to prepare themselves for the work of caring for the sick and physically defective. if, when they have fulfilled all the legal requirements, they find themselves obliged to compete with others who have received almost identical rights and privileges with practically no preparation. If medical laws are necessary to the proper protection of the community, they should apply equally to all who make a business of advising or treating people, regardless of the disease or defect from which they suffer, or of the methods or measures employed. It is impossible for the state to discriminate between physicians, opticians, and the various "pathies" without injury to the cause of professional elevation. A single standard must be created for all, and with its requirements all should comply.

The committee on legislation of the Medical Society of the State of New York has fought these legislative battles successfully in the past and will continue to do so if the profession will back us as it always has. The members of the legislature have no knowledge of the merits of this and similar measures, and look to the medical profession for advice and guidance. The legislature is made up of fair-minded, intelligent and loyal citizens; and when pernicious laws affecting the public health are enacted, it is, as a rule, because citizens who are not members of the legislature neglect to do their duty. We urge the members of the medical profession resolutely to oppose this "Optometry Bill," and its defeat is assured.

FRANK VAN FLEET, Chairman,
Committee on Legislation, Medical Society of the State of New York.
60 East 77th Street, New York City.

### Tuberculosis in Prisons.

ST. PAUL, Jan. 14, 1904.

*To the Editor:*—In an editorial, January 2 (p. 36), you draw attention to the fact that New York State has led the way in providing the first isolation wards for the treatment of tuberculous prisoners. You do not mention the date of such action, but I presume it was recent. If so, New York is not the first state to make such provision for prisoners.

Dr. B. J. Merrill, physician in charge of the prison at Stillwater, Minn., established the system of isolation, special diet, etc., at that institution in the summer of 1894. He set aside a group of cells that came to be known, in prison parlance, as "Tuberculous Row." With any symptoms of tuberculosis showing, a prisoner was subjected to a careful examination, physical and bacteriologic, and if the presence of the disease was established he was at once placed in a cell in the "Tuberculous Row." This does not mean that he was placed in an infected cell; quite the reverse, for these cells and their contents received special attention, and all bedding and clothing were disinfected and laundered separately. Special diet was given. The prisoner was required to spit into a spit cup containing a disinfectant, and special care was given to the daily cleansing of the cell. If able to work, he was assigned a task in the open air. This custom has been continued to the present time under Dr. Merrill's supervision.

In 1897 Dr. Merrill informed me that since the above method of isolation went into effect, in 1894, there has been a decrease of 52 per cent. in the number of cases of tuberculosis. At that time (October, 1897) in this prison of 493 convicts there were only 6 who were tuberculous.

At present (Jan. 12, 1904) there are 6 tuberculous patients at Stillwater out of 630, and these were tuberculous when they entered the prison. All have improved since admission. All are kept in the open air as much as possible, and all are on a special hospital diet.

I think Dr. Merrill was the pioneer in this work.

H. M. BRACKEN,
Secretary Minnesota State Board of Health.

### Offensive Commercialism.

CHICAGO, January 16, 1904.

*To the Editor:*—A few days ago I received through the mail an advertising circular from the Colorado Lithia Water Company, 167 East Van Buren Street, Chicago, and accompanying it and enclosed was a slip of pink paper neatly folded and marked "Personal." I enclose this slip and request that you publish it in THE JOURNAL as an example of an offensive commercialism of which the entire profession must disapprove.

ARTHUR R. ELLIOTT.

The slip referred to reads as follows:

"We will pay you $1.00 for each customer sent us or prescription ordering case or demijohn of water. (See priced card.) Cash sent you at once.

"COLORADO LITHIA WATER CO."

### Prevention of Typhoid Fever.

Cody, Neb., Jan. 12, 1904.

*To the Editor:*—In reading the excellent paper and discussion in the last issue of The Journal, on prevention of typhoid, I wish to add the boiling as well as scalding of all dishes and tableware. In this remote, ranching, watershed locality typhoid is commencing to occur (imported). Hotel knives and forks, etc., seem conveyors from transients to residents. Cases guarded as above with, of course, other precautions, have been limited to one in a family, while those not under such care have spread. T. F. Campbell, M.D.

## Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### LITERATURE ON ILLEGITIMACY.

Detroit, Jan. 11, 1904.

*To the Editor:*—I am desirous of consulting what literature there is available on the subject of illegitimacy or bastardism. Can you refer me to any material? J. E. D.

Answer.—The medical aspects are well discussed from one point of view in articles by Dr. Hastings H. Hart, entitled "The Physician and the Illegitimate Child," *Illinois Medical Journal*, August, 1902, and the "Illegitimate Child in Chicago," *Chicago Medical Recorder*, March 15, 1903. Another aspect of the case was discussed with considerable wealth of historical references by Dr. E. C. Spitzka in a continued article in the *Alienist and Neurologist*, beginning April, 1901, entitled "The Legal Disabilities of the Natural Child," in which he takes a harsher view of the subject. The subject is one of sociologic rather than of medical import and more will probably be learned from sociologic than from medical literature at the present time.

### SMALLPOX AND CUBAN ITCH.

Trafford City, Pa., Jan. 12, 1904.

*To the Editor:*—Please describe the following diseases: Cuban itch, Porto Rico chicken-pox and several other diseases or names of supposed diseases. Are they distinct diseases or are they not mild forms of smallpox (varioloid, discrete smallpox)? Please give some reliable information on this subject or refer to some works. T.

Answer.—The disease called Cuban itch, Porto Rico chicken-pox, etc., is now generally recognized as a modified form of smallpox, capable, however, of propagating the severer form of the disease. In epidemics the severer type has been present in many cases. The subject was well discussed by Dr. James Nevins Hyde in a letter to the Illinois State Board of Health and published by that board in 1900. It is discussed by Drs. Bracken and Happel in papers in The Journal, Sept. 8, 1900, vol. xxxv, and also by others in this and various other medical journals.

## Marriages.

Charles C. Paxton, M.D., to Miss Louise Wegner, both of Archer, Neb., January 5.

Paul Frederic Martin, M.D., to Miss Edna Matilda Kuhn, both of Indianapolis, January 6.

Beverley W. Briscoe, M.D., Garrett, Md., to Miss Bertha K. Shertzer, at Baltimore, January 6.

Patrick M. O'Reilly, M.D., Newark, N. J., to Miss Mary Agnes Hardiman of Baltimore, January 6.

## Deaths.

**Benjamin H. Hartwell, M.D.** Jefferson Medical College, Philadelphia, 1868, a member of the American Medical Association; from 1871 to 1877, coroner of Middlesex County, Mass., and since the abolition of that office, one of the medical examiners for the county; a member of the legislature in 1888, and surgeon in the state militia for three years, died at his home in Ayer, January 6, from pneumonia, aged 58.

**Stuart H. Reed, M.D.** College of Physicians and Surgeons, New York, 1881, died at his residence in Madison, N. J., January 6, after an illness of less than one week, from pneumonia, aged 49. He was a member of New Jersey State Medical Society, Morris County District Medical Society, and Morristown Medical Club.

**James Francis Ferguson, M.D.** New York University, 1860, assistant surgeon Second New York State Militia, a prisoner in Libby Prison, afterward major and surgeon of the 165th New York Volunteer Infantry, died at his home in Central Valley, N. Y., January 6, from paralysis, after a long illness, aged 64.

**Harvey C. Fraker, M.D.** University of Wooster, Cleveland, 1873, professor of pathology in the Ohio Medical University, and city bacteriologist of Columbus, Ohio, died at his home in that city, January 9, from aneurism of the aorta, after a long illness, aged 53.

**Frederick H. Stahle, M.D.** Cooper Medical College, San Francisco, 1888, formerly superintendent of the City and County Hospital in that city, committed suicide by inhaling illuminating gas, at a lodging house in San Francisco, January 5, aged 41.

**Charles W. Bishop, M.D.** Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, of Tinley Park, Ill., was caught between two street cars in Chicago, January 11, and sustained injuries from which he died on the same day.

**J. E. Pierce, M.D.** Central College of Physicians and Surgeons, Indianapolis, 1895, coroner of Henry County, Ind., died at his office in Middletown, January 9, from the effects of a self-inflicted gunshot wound of the head, aged 40.

**George Winslow Foster, M.D.** Medical School of Maine at Bowdoin College, Brunswick, 1871, a member of the Maine Medical Association, and superintendent of the Eastern Maine Insane Hospital, Bangor, died in that city, January 5, aged 58.

**Margaret P. Buckman, M.D.** Woman's Medical College of Pennsylvania, Philadelphia, 1884, died at her home in Trenton, N. J., January 7, from scarlet fever, contracted while caring for her eldest child, after an illness of four days, aged 42.

**Robert Emmet Young, M.D.** University of Pennsylvania, Philadelphia, 1871, first superintendent of the State Hospital for Insane, No. 3, Nevada, died at his home in Jefferson City, Mo., January 8, from pneumonia, aged 65.

**Henry A. Cohrs, M.D.** Long Island College Hospital, Brooklyn, 1892, was found dead in the drug store in Brooklyn, in which he was employed, January 9, aged 37. Death is supposed to have been due to heart disease.

**W. C. Fisher, M.D.** Atlanta College of Physicians and Surgeons, 1881, county physician of Fulton County, Ga., died at his home near Bolton, January 6, from pneumonia, after an illness of one week, aged 49.

**L. D. McKinley, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1885, formerly superintendent of the Topeka (Kan.) State Hospital, died at Marshall, Ind., January 1, aged 68.

**Joseph W. W. Marshall, M.D.** Medical College of the State of South Carolina, Charleston, 1846, once a member of the legislature, died at his home in Abbeville, January 6, aged 83.

**Henry B. Wiggs, M.D.** Memphis (Tenn.) Hospital Medical College, 1896, of Russellville, Ark., died at St. Vincent's Infirmary, Memphis, January 6, after a long illness, aged 67.

**Edward Luther Griggs, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1864, was found dead in bed at his home in Waterbury, Conn., January 6, from heart disease, aged 65.

**Frank W. Shaw, M.D.** New York University, 1885, of Brooklyn, N. Y., died in Seney Hospital in that city, January 9, from the effects of an overdose of opium, aged 38.

**David S. Bowlby, M.D.** College of Physicians and Surgeons, New York, 1853, of Berlin, Ont., died from chronic bronchitis in Rome, Italy, December 31, after a long illness.

**William F. Lazelle, M.D.** University of Vermont, Burlington, 1857, of Plainfield, Vt., died at the home of his son in Barre, Vt., January 5, after a protracted illness, aged 68.

**Hiram Temple, M.D.** Berkshire Medical College, Pittsfield, Mass., 1865, died at his home in Charlemont, Mass., January 6, from pneumonia, aged 64.

**Cornelius E. Billington, M.D.** New York University, 1864, died at his home in New York City, January 8, after an illness of several weeks, aged 60.

**Charles G. Frowert, M.D.** University of Pennsylvania, Philadelphia, 1874, died suddenly at his home in Philadelphia, January 9, aged 53.

**Hiram W. Vail, M.D.** Cleveland Medical College, 1880, of Rogers, Ohio, died at Pittsburg, Pa., January 13, from heart disease, aged 58.

**Levi H. Fisher, M.D.** Tulane University, New Orleans, 1853, died from pneumonia at his home in Shreveport, La., January 9, aged 70.

**John C. Langford, M.D.** Medical College of Alabama, Mobile, 1893, of Morales, Texas, died January 4, from poison accidentally taken.

**John R. Boyd, M.D.**, formerly of Defiance, Iowa, died at his home in Cleveland, Ohio, January 5, from Bright's disease, aged 59.

**William P. Armstrong, M.D.** Homeopathic Hospital College, Cleveland, 1866, died at his home in Salina, Kan., January 6, aged 60.

**Frederick H. S. Ames, M.D.** Toronto University, 1880, died at his home in Denver, Colo., January 4, after a long illness, aged 45.

**James E. Golley, M.D.** College of Physicians, Baltimore, 1894, died at his home in Templeville, Md., January 6, from pneumonia.

**William E. Whitehead, M.D.** Medical College of Ohio, Cincinnati, 1878, died at his home in Brownstown, Ind., January 7.

**George P. Hackenberg, M.D.** New York University, 1851, died at his home near Austin, Texas, January 8, aged 80.

**Robert Lowry, Jr., M.D.** Louisville Medical College, 1887, died at his home in San Francisco, January 3, aged 40.

**Lewis R. Burns, M.D.** Castleton (Vt.) Medical College, 1847, died at his home in Toluca, Ill., December 30, aged 80.

**Mrs. M. M. Hatfield, M.D.** Homeopathic Hospital College, Cleveland, 1880, died in Denver, January 6.

### Deaths Abroad.

**John Knowsley Thornton, M.B., C.M.**, Edinburgh, 1871, died at his home, Hildersham Hall, Cambridgeshire, England, aged 59. He was one of the most famous and successful abdominal surgeons of Great Britain at the time of his retirements—because of failing health—from hospital practice in 1891 and from private practice in 1898. He was an ex-president of the Harveian Society; fellow and president of the Medical Society of London; fellow of the Royal Medical and Chirurgical Society; member of the Royal Medical Society of Edinburgh, Pathological Society of London, and British Medical Association, and was an honorary fellow of the American Gynecological Society and a corresponding fellow of the Boston Gynecological Society.

**Karl Emmert, M.D.**, professor emeritus of medical jurisprudence at Berne, died at his home, December 23, aged 92. His best-known work is a "Manual of Surgery," issued in 1850, and followed by frequent new editions and numerous works on his specialty.

**Karl Gebhard, M.D.**, professor of gynecology and obstetrics at Berlin, died, December 23, aged 42. He published, among others, a work on the pathologic anatomy of the female genitalia, and has been a frequent contributor to medical periodicals.

## Book Notices.

Hypnotism. Its History, Practice and Theory. By J. Milne Bramwell, M.B., C.M. Cloth. Pp. 477. Price, $4.50 net. Philadelphia: J. B. Lippincott Co. 1903.

The subject of hypnotism is one that is always of interest. It stands on the edge of the marvelous, and on what is often considered by the scientific physician as debatable ground. Dr. Bramwell is the leading English advocate of its utility in therapeutics, and he states his side of the question very ably in the book before us. We ourselves have not the full confidence in the method that he shows, but will admit that it has an occasional utility. Its applicability in general practice is, we think, somewhat doubtful, notwithstanding the remarkable results reported by the author. Dr. Bramwell goes over the history of hypnotism very fully, but it is remarkable that he should leave out so well known a writer as Beard, whose contributions, though not numerous, are yet sufficiently noteworthy to be mentioned. In fact, the history does not include the early American investigations of the subject, some of which were of value, though not always made by scientific men. In spite of its onesidedness the medical man who wishes to be informed on the subject of hypnotism will find this book very useful; in fact, it will be a profitable reference work for any neurologist or scientific physician.

Portfolio of Dermochromes. By Professor Jacobi of Freiburg in Breisgau. English Adaptation of Text by J. J. Pringle, M.B., F.R.C.P., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Part I. Half Leather. Price, $15 for Complete Work. London and New York: Rebman, Ltd. 1903.

This is intended especially for the general practitioner, who will find the illustrations in nearly every instance true to nature, although slightly overcolored in some instances. The more common cutaneous disorders have been selected for illustration and not the rare ones which are seldom seen and which are of special interest to the professional dermatologist alone. The diagnosis of skin diseases is usually a difficult problem for the average physician and no amount of descriptive text will take the place of a good picture if it is at all what it should be. The illustrations are from models and are reproduced in a four-color process called, according to the translator, citochromy, a process invented by Dr. Albert of Munich. There are nearly 100 illustrations in the volume before us. The work is not intended as a text-book, and is, therefore, not overburdened with text, although sufficient descriptive matter accompanies the illustrations to satisfy—the essential facts being presented in a condensed form. As a whole the book is a very satisfactory one, and is to be commended to those desiring an atlas on skin diseases.

Homophonic Conversations in English, German, French and Italian, Being a Natural Aid to the Memory in Learning Those Languages. By C. B. and C. V. Waite. Cloth. Pp. 137. Price, $1.00. Chicago: C. V. Waite & Co.

This is a convenient little chrestomathy for the German, French and Italian languages, covering the ordinary conversational expressions that are required by one traveling. The aim has been to make the spelling fairly phonetic in the three languages, employing nearly five hundred homophonic words which are also given in a complete alphabetical list at the end of the work.

## Association News.

**Place of Session of the American Medical Association for 1905.**—Attention is called to the action taken at the last session of the American Medical Association to the effect that any city wishing to invite the Association to meet at that place should present the invitation, together with all available facts concerning hotel accommodations, number and seating capacity of halls available for section meetings, intramural means of transportation, railroad facilities, etc., at least three months before the annual session of the preceding year. In accordance with the above, it is hoped that those cities which desire the Association in 1905 will send their invitations, with all information possible, on or before March 1, 1904.

M. L. Harris, M.D.,
Chairman Committee on Place of Session and Transportation,
100 State Street, Chicago.

## State Boards of Registration.

### COMING EXAMINATIONS.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

New York State Board of Regents, at New York, Albany, Syracuse and Buffalo, Jan. 26-29. Secretary, James Russell Parsons, State Capitol, Albany.

Nebraska State Board of Health, State House, Lincoln, Neb., Feb. 10-11. Secretary, George H. Brash, M.D., Beatrice.

Kansas Board of Medical Examiners, State House, Topeka, Feb. 12. Secretary, O. F. Lewis, M.D., Hepler.

**Nebraska Report.**—Dr. George H. Brash, Beatrice, secretary of the State Board of Health, reports the written examination held at Lincoln, Nov. 11-12, 1903. One applicant took the examination in 8 subjects, on which 80 questions were asked, and received a grade of 92. The percentage required to pass was 75. He was a graduate of Bellevue Hospital Medical College in 1903.

**Michigan Report.**—Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine reports the written examination held at Lansing, October 13-16, 1903; 10 applicants appeared, 7 passing; the number of subjects examined in was 19; total questions, 100; percentage required to pass, 75.

Exclusive of two undergraduates who failed, with grades of 73 and 70, the applicants were from the following colleges:

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Imperial Alexander Unive., Finland | (1896) | 87 |
| University of Toronto (two) | (1903) | 88, 87 |
| Royal Medical College, Kingston | (1890) | 88 |
| Trinity University, Toronto | (1884) | 91 |
| McGill University, Montreal | (1903) | 89 |
| Washington University, St. Louis | (1899) | 89 |

FAILED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Dartmouth Medical Coll., Hanover, N. H. | (1886) | 72 |

**Iowa October Report.**—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports that at the written examination held at Des Moines, October 21 and 22, 1903, out of 24 applicants, 12 passed. The subjects examined in numbered 8; total questions, 80; percentage required to pass, 75. The colleges represented, dates of graduation and grades attained are as follows:

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Coll. of P. and S., Chicago | (1902) 80, (1903) | 85 |
| Hahnemann Med. Coll., Chicago | (1903) | 78 |
| Iowa Coll. P. & S., Des Moines | (1903) | 75 |
| Hosp. Coll. Med., Louisville | (1903) | 82 |
| Jefferson Med. Coll., Philadelphia | (1902) | 83 |
| N. W. Univ., Chicago | (1903) | 87+ |
| Rush Med. Coll., Chicago | (1903) | 85+ 87 |
| Univ. Copenhagen | (1888) | 77+ |
| Univ. Edinburgh | (1903) | 91+ |
| Univ. Nebraska | (1903) | 90+ |

FAILED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Univ. Med. Coll., Kansas City, Mo. | (1902) 70, (1903) | 40+* |
| Iowa Coll. P.& S., Des Moines | (1902) | 34+ |
| Coll. P. & S., Kansas City, Kan. | (1900) | 59+ |
| St. Louis P. & S. | (1902) | 74+ |
| Chicago Hom. | (1903) | 72+ |
| Coll. P. & S., Chicago | (1899) | 66+ |
| Eclectic Med. Inst., Cinn. | (1903) | 64+* |
| Barnes, St. Louis | (1903) | 71+* |
| Omaha Med. Coll., Nebraska | (1903) | 70+* |
| Univ. of Nebraska | (1903) | 67+* |
| Rush Med. Coll., Chicago | (1900) | 67+† |

*Second Examination. †Fourth Examination.

The questions asked were as follows:

PRACTICE OF MEDICINE.

1. Is auto-infection a factor in the production of disease? Give example. 2. What is a zymotic disease? Give three examples. 3. On what symptoms would you base a diagnosis of typhoid fever? Give treatment, including diet. 4. Give symptoms and treatment of acute dysentery. 5. Give etiology and treatment of scarlet fever. 6. Give symptoms and treatment of cerebrospinal meningitis. 7. Give treatment and prognosis in erysipelas. 8. Give symptoms and treatment of spasmodic croup. 9. Give symptoms and treatment of acute catarrhal bronchitis in children. 10. What are the causes and give treatment of palpitation of the heart.

ECLECTIC PRACTICE.

1. How would you distinguish acute bronchitis from pneumonia? (b) Give the usual specific treatment for each. 2. Differentiate the classes of croup, and give a treatment for each. 3. Define hepatic colic, nephritic colic, lead colic, and uterine colic. Give brief treatment for each. 4. Mention the specific drugs useful in influenza with coryza, fever and muscular pains. 5. Write a prescription for cholera morbus. 6. Differentiate between varicella and variola discrete in first stages. 7. State the period of incubation of scarlet fever and measles: describe the character of the rash in each, and state when and where it first appears. 8 Describe (a) Bell's paralysis, (b) Cheyne-Stokes respiration. 9. Define neurasthenia and give etiology, symptomatology and treatment. 10. Give etiology, diagnosis and treatment of malarial fever.

HOMEOPATHIC PRACTICE.

1. Give pathology, symptoms and treatment of membranous croup. 2. Describe a case of scarlet fever with symptoms and course of disease. Give treatment for same. 3. How would you treat a case of carbolic acid poisoning? Name its best antidote. 4. What are the symptoms of renal colic? Give your treatment for same. 5. Give etiology, pathology, symptoms and treatme [illegible] Define hydrocephalus. Give your treatment and [illegible] etiology and treatment of eclampsia infantum [illegible] chicken-pox and smallpox, and give treatment [illegible] Give your treatment for cerebral apoplexy. 10 [illegible] means would be necessary to determine between "retention and suppression" of urine. Name remedy for each condition with indications for their use.

OBSTETRICS.

1. What are the conditions necessary to impregnation and the normal development of the ovum? 2. How does the impregnated ovum and the embyro receive the material needed for their development? Explain fully. 3. (a) Describe the changes that take place in the breasts as a result of pregnancy. (b) What disease of the breasts is most apt to follow labor and what prophylactic measures would you adopt to prevent it? 4. (a) What terms are used to denote an interrupted pregnancy and when applied? (b) What would you do to prevent the attendant dangers of an interrupted pregnancy? Explain in detail. 5. Give diagnosis, symptoms and treatment of eclampsia. 6. (a) What do you understand by the kidney pregnancy? (b) Give probable causes of the changes. (c) What symptoms and conditions are to be found in such cases? 7. Called to attend a primipara in labor, and finding head in pelvic cavity, presentation normal, os fully dilated, pains becoming weak and inefficient, and woman becoming exhausted; what would you do? Explain in detail. 8. Give etiology, symptoms, sequelæ and treatment of septic endometritis (non-specific). 9. Differentiate between "complete and incomplete" lacerations of the perineum. When should lacerations of the perineum be repaired? Why? 10. What is subinvolution? What are the conditions present? Give symptoms and treatment.

SURGERY.

1. Differentiate chancre, chancroid, and venereal warts, and give treatment for each. 2. How would you tell an empyemia from an ordinary case of pleurisy with serous effusion, and how would you treat each? 3. In what class of cases would you give ether, chloroform, bromid of ethyl, and why? 4. What are the danger signals in general anesthesia? 5. Give the general points of difference between malignant and non-malignant tumors. 6. Under what circumstances would you resort to plugging the posterior nares? (b) Describe the operation. 7. What are the general principles of antiseptic surgery, and what is the distinction between antiseptic and aseptic? (b) Name three of our best antiseptic agents. 8. Give the symptoms found in the unconsciousness of cranial trauma demanding prompt operative treatment. (b) Give differential diagnosis between coma due to brain concussion and alcoholism. 9. Give symptoms and treatment for fracture of lower end of the tibia. 10. What period of time is occupied by the various processes necessary for the repair of fracture? (b) What complications are common to all fractures? (c) In what fractures is the union ligamentous?

MATERIA MEDICA.

1. Give action and dose of creosote. 2. What drug would you recommend as a prompt emetic? State dose. 3. Give physiological action of digitalis. 4. Describe the effect of atropin. 5. Treatment of morphin poisoning. 6. Give local effect of tanic acid on mucous membranes. 7. Name and give doses of three cardiac stimulants. 8. Give physiologic action of the nitrates. 9. Define a diuretic; name three and give doses. 10. Give chief symptoms of poisoning by mercury.

HOMEOPATHIC MATERIA MEDICA.

1. What do you understand by modality. Give illustration. 2. In what type of amenorrhea would you use pulsatilla and on what symptoms would you prescribe it? 3. Differentiate between sanguinaria, bryonia and kali carb. in pleuropneumonia. 4. In typhoid fever what symptoms would indicate the exhibition of rhus. tox, of phosphorus, of arsen. 5. Differentiate between the headache of ipecac and iris. 6. State the difference between the gastric symptoms calling for kali. bichr. and lycopodium. 7. Give definite picture of toxic effects of terebinth on the urinary system. 8. What is macrotin. What its chief sphere of action and symptoms indicating its use. 9. Name three remedies you would use in cholera morbus with specific indication for the use of each.

ECLECTIC MATERIA MEDICA.

1. Change one drop, one dram, one ounce and one pint to metric system. 2. Name the most common diuretics, and describe their action. 3. What uses are made of permanganate of potassium. 4. Name the most common laxative, hydragog, saline and cholagog purgative and describe their action. 5. Grade the dose of remedies by the age of the patient. 6. Mention some of the specific glandular remedies. 7. From what is cocain obtained? State its therapeutic uses and give the dose. 8. What is a sedative? Name four of the most prominent. 9. From what is glycerin obtained? State some of the therapeutic uses of glycerin. 10. What are the chief preparations, doses, physiologic actions and therapeutic uses of digitalis?

CHEMISTRY.

1. How can magnesia be distinguished from starch? 2. State difference between sulphate and sulphite. 3. What is formed when phosphorus burns? 4. Give the essential properties of the element nitrogen. 5. How can calomel be distinguished from corrosive sublimate? 6. How could you prove the presence of arsenic? 7. Give chemical constitution of iodoform. 8. How can oxygen be obtained from oxid of mercury? 9. What is chloroform and how is it made? 10. How would you test for sugar and albumin in urine?

ANATOMY.

1. Locate the circle of Willis and make drawing of same, showing location and names of vessels composing it. 2. Give boundaries of the popliteal space and name coverings and contents. 3. Describe the shoulder joint and name its ligaments. 4. Name the several divisions of the small intestines. State names of coats, length, caliber and names of glands found in each division. 5. Name the muscles having their origin or insertion in whole or in part from the upper third of the humerus. 6. State the origin, foramen of exit course, distribution and function of the pneumogastric. 7. What is connective tissue? Name the various forms and describe each. 8. Differentiate between a direct and an indirect inguinal hernia. Give the coverings of each. 9. Locate the solar plexis and state what structures are in contact with it. 10. Describe the pancreas, giving a, location; b, shape; c, color, d, blood and nerve supply.

PHYSIOLOGY.

1. Name and describe three of the component parts of the blood. 2. How many coats have the veins and how do they differ from the coats of the arteries? 3. Give the size, weight, structure, location and function of the kidneys. 4. Describe a complete revolution of the heart. 5. How is nutritive material conveyed to the blood? 6 What agency has the pancreatic juice in the digestion of foods? 7. What is meant by the "greater" and "lesser" circulation? 8. What is osmosis? Where does it normally occur in the human organism? 9. What are the functions of the pneumogastric nerve? 10. Describe structure, origin, distribution and office of the portio mollis (8th pair cranial) nerves.

PATHOLOGY.

1. Give the pathology of vesicular emphysema and name the associating conditions of the heart and general circulation, and explain them. 2. (a) Name the pyogenic bacteria and the conditions that favor their development; (b) name ten pathogenic bacteria. 3. (a) Define immunity; (b) explain the humoral, (c) the phagocytic (d)

and the lateral or side chain theories of immunity. 4. Give the differential pathology of atrophic and hypertrophic cirrhoses of the liver and the relation that each bears to the production of jaundice, and to obstruction of the portal circulation. 5. What is phagocytosis, metaplasia, a toxin? 6. (*a*) Define gangrene. (*b*) Give the pathology of dry gangrene. (*c*) Give the pathology of moist gangrene. 7. Name the different tissue degenerations and give the pathology of each. 8. How would you demonstrate the presence of tubercular bacilli? 9. Give the pathology of interstitial nephritis. 10. What structures are formed from the epiblast, from the hypoblast, and from the mesoblast?

## The Public Service.

### Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending Jan. 16, 1904:

Hutton, Paul C., asst.-surgeon, granted thirty days' leave on account of sickness.

Van Dusen, Jas. W., asst.-surgeon, relieved from Columbus Barracks, Ohio, and ordered to West Point, N. Y.

Stark, Alexander M., asst.-surgeon, relieved from duty at West Point, N. Y., and assigned to duty as assistant to the attending surgeon, Washington, D. C., until April 1, when he will assume the duties of attending surgeon.

Banister, Wm. B., surgeon, relieved from duty as attending surgeon, Washington, D. C., April 1, 1904, and ordered to Jefferson Barracks, Mo., for duty.

Brown, Henry L., contract surgeon, arrived at Columbus Barracks, Ohio, December 18, for temporary duty, and has since been relieved from further duty at Fort Sheridan, Ill., and assigned to permanent duty at Columbus Barracks.

Mabry, William C., contract surgeon, relieved from duty at Columbus Barracks, Ohio, and directed to proceed to Fort Sheridan, Ill., for duty.

Brewer, Isaac W., contract surgeon, reported at Whipple Barracks, Ariz., for temporary duty.

White, J. Samuel, contract surgeon, relieved from duty at Fort Yellowstone, Wyo., and assigned to duty at Fort Snelling, Minn.

Gregory, William G., contract surgeon, granted one month's leave of absence from Fort Apache, Ariz.

Macy, Fred S., contract surgeon, who is now on leave of absence at Somerville, Mass., has been relieved from further duty in the Division of the Philippines, and assigned to duty, at the expiration of his leave, at Allegheny Arsenal, Pa.

Mills, Frederick H., contract surgeon, ordered from his home at South Dayton, N. Y., to San Francisco, en route to Philippine service.

Gregory, Verdo B., contract surgeon, ordered from his home at Janesville, Wis., to San Francisco, en route to Philippine service.

Baily, Howard H., Hughes, Leonard S., McCullough, Edward A., and Unger, Isedor M., contract surgeons, arrived at San Francisco January 14 on the transport *Sheridan,* on leave of absence from the Division of the Philippines.

Jordan, Edward H., and Underwood, Fred R., contract surgeons, arrived at San Francisco January 14 on the transport *Sheridan,* and are en route to their homes for the purpose of leaving the service.

### Navy Changes.

Changes in the medical corps of the Navy for the week ending Jan. 16, 1904:

Crandall, R. P., surgeon, detached from the Naval Station, Guam, L. I., and ordered to the *Wisconsin.*

Murphy, J. A., P. A. surgeon, commissioned a P. A. surgeon from March 3, 1903.

Heiner, R. G., and Stoops, R. E., appointed asst.-surgeons with rank of lieutenant junior grade, from Dec. 26, 1903.

### Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Jan. 14, 1904:

White, J. H., surgeon, granted leave of absence for seven days from January 11.

Guiteras, G. M., surgeon, detailed as inspector of unserviceable property at Havana, Cuba.

Wickes, H. W., P. A. surgeon, granted leave of absence for two days from January 16.

Grubbs, S. B., P. A. surgeon, granted leave of absence for ten days.

Amesse, J. W., asst.-surgeon, granted extension of leave of absence on account of sickness for ten days from January 11.

Duke, B. F., A. A. surgeon, granted leave of absence for five days from January 14.

Tidd, R. M., A. A. surgeon, granted leave of absence for seven days under Paragraph 210 of the Regulations.

Tuttle, Jay, A. A. surgeon, Department letter granting leave of absence for ten days from Dec. 21, 1903, amended to read five days.

Walker, R. T., A. A. surgeon, granted leave of absence for twenty days from January 5.

Maguire, E. S., pharmacist, granted extension of leave of absence for ten days from January 8.

Richardson, S. W., pharmacist, to proceed to New York, for special temporary duty.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Jan. 15, 1904:

#### SMALLPOX—UNITED STATES.

California: Fresno, Dec. 1-31, 2 cases.

Illinois: Belleville, Dec. 19-Jan. 9, 12 cases, 1 death; Jan. 2-9, Chicago, 1 case; Danville, 2 cases.

Indiana: Evansville, Jan. 6, 14 cases.

Louisiana: New Orleans, Jan. 2-9, 3 cases.

Maine: Jan. 7, Milford, 2 cases; Orono, 1 case.

Michigan: Grand Rapids, Jan. 2-9, 1 case.

Missouri: St. Louis, Dec. 26-Jan. 9, 6 cases.

New Hampshire: Jan. 2 9, Manchester, 6 cases; Nashua, 1 case.

New Jersey: Jan. 2-9, Camden, 2 cases, 1 death; Trenton, 1 case.

New York: Buffalo, Dec. 26-Jan. 9, 5 cases.

Ohio: Ashtabula, Dec. 28-Jan. 4, 1 case; Cincinnati, Dec. 24-Jan. 8, 6 cases, 1 death; Cleveland, Jan. 1-8, 2 cases; Dayton, Jan. 2-9, 1 case; Youngstown, Dec. 26 Jan. 9, 37 cases.

Pennsylvania: Jan. 2-9, Braddock, 6 cases; Philadelphia, 83 cases, 25 deaths; Pittsburg, 20 cases, 4 deaths; Reading, Jan. 4-11, 1 case.

South Carolina: Charleston, Jan. 2 9, 2 cases.

Tennessee: Nashville, Jan. 2-9, 1 case.

Texas: San Antonio, Dec. 1-31, 6 cases.

Utah: Salt Lake City, Jan. 2 9, 1 case.

Wisconsin: Milwaukee, Jan. 2-9, 10 cases.

#### SMALLPOX—INSULAR.

Philippine Islands: Manila, Nov. 14-Dec. 5, 2 cases, 1 death.

#### SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Dec. 12-19, 16 cases; Trieste, Dec. 5-12, 21 cases.

Brazil: Pernambuco, Nov. 1-31, 20 deaths.

British Guiana: Demerara, Oct. 31 Nov. 28, 62 cases.

Chile: Antofogasta, Nov. 1-30, 8 deaths.

France: Paris, Dec. 12-26, 31 cases, 3 deaths.

Great Britain: Edinburgh, Dec. 12-19, 1 case; Dec. 19-26, Glasgow, 64 cases, 2 deaths; London, 7 cases; Manchester, 2 cases; Newcastle-on-Tyne, 1 case; Dec. 26-Jan. 2, Leeds, 1 case; Southampton, 1 case; Nottingham, Dec. 12 26, 11 cases.

India: Bombay, Dec. 8-15, 4 deaths.

Italy: Catania, Dec. 17-24, 1 death; Messina, Dec. 11-18, 1 death.

Malta: Dec. 5-19, 8 cases.

Netherlands: Amsterdam, Dec. 19-Jan. 2, 6 cases, 1 death.

Russia: Moscow, Dec. 12-19, 1 case, 1 death; Odessa, Dec. 12-26, 3 cases; St. Petersburg, Dec. 5-19, 101 cases, 2 deaths; Warsaw, Nov. 21-28, 3 deaths.

Spain: Santander, Dec. 28-Jan. 4, 3 cases, 1 death.

Turkey: Smyrna, Dec. 13-20, 6 deaths.

Venezuela: Maracaibo, Oct. 24-31, 1 case, 1 death.

#### YELLOW FEVER—FOREIGN.

Mexico: Merida, Dec. 20-Jan. 2, 4 cases, 2 deaths.

#### PLAGUE—INSULAR.

Philippine Islands: Manila, Nov. 14-Dec. 5, 1 case, 1 death

#### PLAGUE—FOREIGN.

China: Hongkong, Nov. 29-Dec. 5, 1 death.

Egypt: Alexandria, Dec. 5-12, 3 cases, 2 deaths.

India: Bombay, Dec. 8-15, 56 deaths; Calcutta, Dec. 5-12, 13 deaths; Karachi, Dec. 6-13, 8 cases, 7 deaths.

Mauritius: Oct. 9-Nov. 5, 377 cases, 211 deaths.

South Africa: Cape Colony, Nov. 14-21, 1 death.

#### CHOLERA—INSULAR.

Philippine Islands: Nov. 14-Dec. 5, Manila, 13 cases, 11 deaths; Provinces, 643 cases, 567 deaths.

#### CHOLERA—FOREIGN.

Afghanistan: Herat, Dec. 21, present.

India: Bombay, Dec. 8-15, 1 death; Calcutta, Dec. 5-12, 38 deaths.

Japan: Nagasaki, Nov. 30, 130 cases, 64 deaths.

Java: Batavia, Nov. 28-Dec. 5, 14 cases, 2 deaths.

Straits Settlements: Singapore, Nov. 14-21, 4 deaths.

Turkey in Asia: Dec. 7, 37 cases, 30 deaths.

## Medical Organization.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.—The intention of the officers of this association to put it on a high plane is evidenced by the change in the requirements for membership, which now provide that the applicant must not only be a graduate of a recognized medical college, but that he shall be a member in good standing of both his county and state medical society.

### Illinois.

SIXTH DISTRICT MEDICAL SOCIETY.—January 14 Dr. Luther J. Harvey of Griggsville, councilor for the Sixth District of Illinois, called together the physicians in his district, for a joint meeting of the fourteen societies which comprise the district. The meeting was held at Jacksonville by invitation of the Morgan County Medical Society. The program for the afternoon consisted of a report from the secretary of each county society. The secretaries had been especially requested by the councilor to present to the meeting the various difficulties under which each county society labored. Dr. J. N. McCormack, chairman of the Committee of the American Medical Association on Reorganization, was present and took part in the discussion of these reports, pointing out to the various secretaries how they could overcome the reported difficulties. This proved to be a valuable feature of the meeting. Several papers on scientific subjects were presented by Drs. Lewis C. Taylor, Springfield; James L. Lowrie, Lincoln; Rufus H. Main, Barry, and Thomas J. Pitner, Jacksonville. In the evening all those in attendance were invited to a dinner, which was followed by an address on "Medical Organization" by Dr. J. N. McCormack, Bowling Green, Ky., and an address on the "Diagnosis of Hysteria" by Dr. Hugh T. Patrick, Chicago. Dr. Frank P. Norbury, president of the Morgan County Medical Society, acted as master of ceremonies at the dinner. Those present feel that the meeting will be productive of great good in stimulating interest in county society organization in the district. It gave the members coming from different counties an opportunity to discuss the subject of maintaining live active local societies with each other, and each was enabled to go home with some new ideas gained from his neighbors, as well as from the national organizer, who gave invaluable assistance by practical suggestions of ways to overcome obstacles and difficulties and how to promote interest in the local society and secure the co-operation of all the members of the profession.

### Maryland.

Howard County Medical Society.—This society held its quarterly session at Ellicott City, January 5, and heard an address by Dr. William T. Watson of Baltimore on "Medical Organization."

Anne Arundel County Medical Society.—This society met in Annapolis, January 5, to reorganize under the rules of the American Medical Association. The following officers were elected: Dr. H. Baldwin Gantt, Waterbury, president; Dr. C. R. Winterson, vice-president; Dr. Frank H. Thompson, Annapolis, treasurer; Dr. Benjamin R. Davidson, Davidsonville, recording secretary; Dr. Charles B. Henkel, Annapolis, corresponding secretary, and Drs. George Wells, Annapolis, C. H. Anderson, and J. W. DuBois, Gambrills, censors.

### Rhode Island.

Rhode Island Medical Society.—At the quarterly meeting held in Providence, December 3, Dr. John Champlin, Westerly, reported for the committee on reorganization, recommending the adoption of a new constitution and by-laws. The report was received and action deferred.

### Tennessee.

Warren County Medical Society.—Physicians of the county met at McMinnsville and organized a society, with the following officers: President, Dr. Albert Seitz, McMinnsville; vice-presidents, Drs. H. V. Copenhaver, Pine Bluff, and T. C. Martin, and secretary and treasurer, Dr. Thomas O. Burger, McMinnsville.

### Texas.

Co-operation for the Profession's Advancement.—The following letter has been sent by Dr. F. Paschal, San Antonio, Texas, president of the Texas State Medical Association, to the secretaries of all the component societies in the state:

San Antonio, Tex., Dec. 19.

*Dear Doctor:*—I am anxious to get an expression of opinion from the medical profession of our state as to the measures that in their opinion should be considered by our association for its best interest, advancement and welfare.

I will esteem it a favor if you will kindly communicate with the members of your county society and ask those members who feel inclined to do so, to write me fully, making such suggestions as they may think proper for the good of our association. I will study their recommendations, and in my annual message incorporate such as may be of practical value, and that may help in the upbuilding of the profession and our association.

Please send me the names of all the reputable physicians in your county who have not joined your county society.

Asking that you will kindly give these matters your earliest attention, I beg to remain yours truly, F. Paschal,
President Texas State Medical Association.

## Society Proceedings.

### COMING MEETING.

Medical Society of the State of New York, Albany, Jan. 26 28; 1904.

### AMERICAN SOCIETY OF TROPICAL MEDICINE.

*First Public Meeting, held at the University of Pennsylvania, Philadelphia, Jan. 9, 1904.*

A Vice-President, Dr. James M. Anders, in the Chair.

A brief statement of the scope and workings of the society was made by the secretary, Dr. Joseph McFarland of the Medico-Chirurgical College.

### The Etiology of Yellow Fever.

Dr. James Carroll, U. S. Army, a former member of the commission appointed by the Surgeon-General of the United States to investigate yellow fever at Havana, Cuba, made an address, reviewing in an interesting manner the early researches on the etiology of the disease, giving special consideration to the work of Freire, Sanarelli and Finlay. He then reviewed the work of the commission whose researches have now become world-wide and resulted in the proof that we have no reason to believe that yellow fever is propagated by any other means than the bites of the mosquito known as *Stegomyia fasciata*.

A description of the experiments made to show the infectiousness of fomites seemed to exclude all possibility of yellow fever being transmitted directly. It was with pleasure that the speaker reported that confirmation of all the work of the United States Commission had been given by the more recently appointed French Commission.

### CHICAGO SURGICAL SOCIETY—CHICAGO MEDICAL SOCIETY.

*Joint Meeting, held Jan. 13, 1904.*

The President of the former, Dr. E. Wyllys Andrews, in the Chair.

### Symposium on the Surgical Treatment of Bright's Disease.

Dr. Arthur R. Elliott read a paper entitled "The Medical Aspects of Decapsulation of the Kidneys for the Cure of Chronic Bright's Disease." A study of available statistics showed the total cases to be 76; died, 36; mortality ratio, 47.36 per cent.; improved, 26; improved ratio, 34.21 per cent.; unimproved, 12; unimproved ratio, 15.78 per cent.; rendered worse, 2; worse ratio, 2.66 per cent.; summary: 65.80 per cent. failed to be favorably influenced.

Dr. Elliott emphasized that chronic Bright's disease is a disease of the entire system, of very gradual development, and usually has existed for months and years before it is detected. It is produced by a chronic toxemia, either systemic or infective in origin, producing widespread arterial and cardiac degenerative changes, which, once established, are permanent, and which eventually constitute the most threatening element. General edema or anasarca is often largely a cardiac dropsy from myocardial degeneration. In like manner, developing anuria and uremia may be largely cardiac. In the later stages these cardiac aspects virtually convert the therapeutic problem into a question of sustaining a failing heart. Albuminuric retinitis is a terminal symptom. When it develops, death usually occurs in two years, and to operate hastens death.

General improvement after decapsulation does not prove the procedure justified, for mere hygiene and rest often will do as much. Within three and one-half months after decapsulation a new and usually a tougher fibrous envelope has taken the place of the original capsule. This may account for the many relapses and deaths.

Dr. George F. Suker followed with a paper entitled "A Consideration of the Surgical Treatment of Chronic Bright's Disease from an Ophthalmic Standpoint."

After analyzing statistics, he argued: 1, As at least 25 per cent. of all grades and varieties have retinal or other fundus complications; 2, usually of the degenerative inflammatory type, and, 3, as the cardiovascular system is or shortly will be seriously involved; 4, perhaps undetected; and, 5, proof of a general systemic circulating toxin; and, 6, as the death rate under medical treatment (hospital and private practice) is about 75 per cent. for the first year, and, at least, 85 per cent. for the second year, scarcely any surviving four years, and practically 100 per cent. when operated on; and, 8, as the medical treatment offers as good, if not far better, results; therefore, decapsulation of the kidney for chronic Bright's disease is absolutely contraindicated when a retinitis or a neuroretinitis albuminurica exists, with or without retinal hemorrhages.

DISCUSSION.

DR. E. WYLLYS ANDREWS reported four interesting cases. In three the procedure caused no more than temporary benefit, and in the fourth benefit was ascribed to a coincident nephropexy.

DR. A. J. OSCHNER said there are two distinct classes: One with healthy kidneys, in which a mechanical injury is corrected by fixation and decapsulation, the kidney itself containing the elements which were necessary for its recovery. In the other, the systemic conditions may prevent repair in spite of relief of tension or other burdens. He said sufficient observations had now been made to justify the profession in accepting the conclusions of Dr. Elliott.

DRS. L. L. MCARTHUR, RANDOLPH BRUNSON and ALEXANDER HUGH FERGUSON reported cases. The latter urged differentiation between cases suitable for this operation and those not suitable. He would decapsulate and suspend all tender and floating kidneys, and would decapsulate in certain cases of nephritis. He detailed several cases, and expressed himself as believing that there was a legitimate field for renal decapsulation.

DR. EMIL RIES narrated an interesting case of hematuria treated by decapsulation. From the kidney subsequently removed over six hundred sections were made. He examined every one, and among them there was but one anastomosis, and this was of scar tissue. This proved conclusively the incorrectness of the theory that success of decapsulation was due to anastomoses forming, as far as this example was concerned. He said he was skeptical as to the ultimate results of decapsulation.

DR. R. B. PREBLE called attention to alleged cures of Bright's disease, in which there was no proof of the cases being true chronic Bright's disease. He said that throughout the literature the terms nephritis and chronic Bright's disease were used interchangeably and that they were not identical terms. The difference between the two was clearly pointed out. The internist could not recommend his patients to undergo an operation which showed a mortality of 76 per cent. Renal decapsulation, therefore, was an unjustifiable procedure, without any reasonable, rational explanation having been offered as yet for its use, so far as he knew.

DR. ARTHUR DEAN BEVAN said that the operation was not the surgical treatment of Bright's disease, because the majority of surgeons of the world had never accepted the operation as being a logical procedure. The profession could safely say that stripping of the capsule as a treatment for Bright's disease was a complete failure, and should receive the stamp of disapproval of scientific men. Out of this work there had come some good, because it emphasized the importance of a class of cases in which another operation was of value, namely, in cases of anuria, of essential kidney hematuria, in chronic pyelitis with some nephritis, draining the kidney by a rapid nephrotomy was of a distinct value. It had effected a great many cures, and would accomplish more.

DR. JOSEPH L. MILLER said that in the statistics of Edebohls the analyses and diagnoses were too indefinite to enable anyone to draw any conclusions as to the value of this operation in nephritis. The profession needed a few cases, carefully studied before and after operation, to settle the question.

DR. GUSTAV KOLISCHER thought Drs. Suker and Elliott had struck the keynote, that the value of renal decapsulation was not well established. It was very essential to make diagnoses based on proper conceptions of pathology.

## NEW YORK COUNTY MEDICAL ASSOCIATION.

*Regular Meeting, held Dec. 21, 1903.*

The President, Alexander Lambert, M.D., in the Chair.

### A Review of Some Statistics of Insanity.

DR. WILLIAM MABON, formerly the superintendent of the State Hospital at Ogdensburg, presented this paper. He pointed out that the proportion of insane to population twelve years ago was 1 to 374, now it is 1 to 303. Hospitals for the insane in New York State have an average daily census of 23,000, which was a good basis for the deductions following. During the past year in this state, Dr. Mabon said, 15.31 per cent. of the cases of insanity had been ascribed to moral causes, 53.16 per cent. to physical causes, whereas in 31.51 per cent. the cause could not be ascertained. Among the physical causes intemperance took the first place, as it was the cause in over 14 per cent. of the cases admitted, and was a contributing factor in 30 per cent. of all the cases received. Other physical causes were pregnancy, lactation, the menopause, fevers, privation, epilepsy, epidemic influenza, insolation, injuries and autointoxication. Of over 1,400 persons admitted, 17.71 per cent. apparently inherited the mental disease, 50 per cent. denied such heredity, and in 31.67 per cent. the facts on this point were not obtainable. Of the 73,000 cases treated in these hospitals since 1888, the insanity appeared to be hereditary in 22 per cent. There were twice as many widowed women as widowed men received. The admissions between the ages of 30 and 40 exceeded very largely those of any other decade, over 28 per cent. of all admissions occurring in this decade. Of the 7,619 admissions, only 112 led professional lives. More men than women recover, and, in hospitals, the chance of ultimate recovery was slightly better in acute mania than in melancholia. The death rate was about 5 per cent.

DISCUSSION.

DR. JOSEPH COLLINS severely arraigned the profession and the public generally for the utter lack of proper scientific treatment of the acutely insane. He said that these people did not require fine hospitals and modern laboratories so much as they needed careful medical treatment, such, for example, as would be given to a person ill with typhoid fever. He knew of only one asylum in this country that could boast of providing for this class anything worthy of the name of treatment, and that was the Shepard Asylum in Baltimore. It was all well enough to provide costly homes for the chronic insane, but it was of far greater moment to give succor and the right kind of care and treatment to insanity in its incipiency, and so prevent it, as far as possible, from becoming chronic.

DR. ALEXANDER LAMBERT said that the acutely insane received the treatment Dr. Collins advocated in the New York Infirmary for Women and Children, where a psychopathic ward had been in operation for two years, and was open to physicians who desired to treat their own patients there. He said it was not probable that our knowledge of insanity would be materially advanced except by a study of the brain in action. An effort to prosecute just such a research had taken the form of the New York State Pathological Institute, but its career of usefulness had been cut short because our legislators could not be made to see that it was a better investment for the people to spend a few thousand dollars a year in such study than to vote millions for the maintenance of costly hospitals for the chronic insane. To our shame, it must be said that the real deathblow to this institute was given by three members of the medical profession from other states. Certainly, the state had made great progress in the housing and general care of the insane, and the time was bound to come when the insane would receive proper treatment while the mental disorder was still in the acute stage.

DR. MABON said that scientific treatment of the acutely insane was given in the MacLean Hospital, Massachusetts, and in several of the state hospitals in New York. A very large proportion of those coming to these hospitals are already chronic insane, and proper provision must be made for them. Many of our modern state hospitals are now making an earnest effort to separate the acutely insane from the others and give them proper medical treatment in a special department of the hospital.

DR. FREDERICK HOLME WIGGIN showed specimens from cases of nephrectomy, appendicectomy and laryngectomy, and described the interesting features of each.

## ACADEMY OF MEDICINE OF CLEVELAND.

*Thirteenth Regular Meeting, held Nov. 20, 1903.*

The President, Dr. Harris G. Sherman, in the Chair.

### Chronic Ulcer of the Stomach and Duodenum from a Surgical Standpoint.

Dr. William J. Mayo, Rochester, Minn., in this paper, said that the stomach acts as a fuel storehouse, and in it the food is macerated and broken up by the aid of a weak solution of hydrochloric acid and pepsin; the resulting product is slowly passed on into the small intestine, the first portion of which is more nearly related to the stomach than the intestine, the latter really beginning at the common duct. This first portion of the small intestine, he regards, for its length, as the most frequently diseased part of the alimentary tract. The pylorus is compared to the gizzard of a fowl, as it pulverizes the food. At operations, ring-like constrictions or vermicular movements of this part of the stomach can be seen. Two facts are pre-eminent in the history of gastric ulcer: First, that 75 per cent. occur in the pyloric end, the part most exposed to mechanical injury, and, second, that usually there is a relative increase in the hydrochloric acid. This is an important etiologic factor in the causation of duodenal ulcer above the common duct and occasionally in the appearance of secondary jejunal ulcer after gastro-enterostomy. The statistics as to the frequency of gastric ulcer show that women are affected more than men, especially as regards the small acute ulcer; in about 20 per cent. of cases more than one ulcer exists, and at least 75 per cent. of all gastric ulcers are in the pyloric end; the chronic duodenal ulcer is found most frequently in adult males. The most prominent symptom of chronic ulcer is pain, often burning or boring, but varying in intensity; taking food usually increases it, but may give relief. Periods of freedom from pain, often lasting weeks or months, may lead to the erroneous belief of a cure, only to be followed by a return of the symptoms. Owing to the pain after eating, the patient reduces his diet to a minimum and vomiting is rare unless there be obstruction; hemorrhage in appreciable quantities is rare. Passing the stomach tube may be impossible during the attack of pain; the stomach, however, is not sensitive to touch, but the gaseous distention, which usually occurs, is very distressing. Duodenal ulcer presents symptoms of a similar character, but may be confounded with biliary calculi; the lapse of time between taking food and the onset of pain is not of much value in determining the location of the ulcer.

The general tendency to consider all palpable tumors of the stomach malignant is erroneous. Excess of hydrochloric acid is the only laboratory test of any value and then only as corroborative evidence. Most cases of chronic ulcer develop changes in the size and position of the stomach, due to cicatrices, contractions or adhesions; the most important is a narrowing or fixation of the pylorus leading to the so-called pyloric syndrome of Hartmann—pain, indigestion, gas and hypersecretion; frequently peristaltic waves in the gastric area can be seen. Distention of the stomach with air pumped in with a Davidson syringe will decide the question of dilatation or prolapse. Pyloric obstruction is indicated by dilatation, stagnation and retention of food causing fermentation, late vomiting and emaciation; the condition can be aptly compared to a valvular heart lesion, periods of dilatation and gastric insufficiency alternating with spells of comparative health due to compensation effected by hypertrophy. The best practical test as to loss of motility is the finding of remnants of food in the stomach on using the tube before breakfast. Chemical and microscopic examination of the gastric contents is often of little value. The history and the physical examination of the stomach, especially when artificially distended, usually lead to a correct diagnosis.

Statistics all agree on the frequent failure of medical treatment in these cases. The development of cancer on chronic ulcer is also a risk. He warns against operation in cases of gastric dilatation and gastroptosis without organic lesion. An incision in the median line between the ensiform cartilage and the umbilicus is advised; this allows the movable part of the stomach to be withdrawn from the abdomen; the examination should be thorough, including the fundus, the region of the cardiac orifice, the duodenum and the gall bladder; if one ulcer be found, search must be made to see if others are also present. Enlarged glands in the omenta are useful in locating the lesion; they are usually found in the gastrocolic rather than in the lesser omentum; the examination of the posterior wall may necessitate opening the lesser peritoneal cavity through either the lesser or gastrocolic omentum. Exploration of the interior of the stomach through an incision in the anterior wall is advisable, but even in this way it may be very difficult to locate the ulcer. The indications for the surgeon are the consideration of the ulcer itself and the relief of the complicating dilatation, distortion and adhesions. The keynote is drainage, and for this purpose gastro-enterostomy is the operation of widest application: excision of the ulcer or of the whole ulcer-bearing area, i. e., the muscular pyloric region, as advised by Rodman, may be indicated; pyloroplasty is safe and has a small field of usefulness, but in these cases the gastroduodenostomy of Finney gives far better results. This operation is specially indicated in late cicatricial stenosis and contraction, but will probably often fail in open ulcer; the mortality in either of these procedures is very low. Gastrojejunostomy is the operation of choice, as it drains the stomach to the best advantage, and the new opening will not contract if the pyloric orifice be already contracted or artificially made so at the time of the operation. The formation of secondary peptic ulcer of the jejunum, a tendency to drag on the point of attachment, and secondary contraction of the opening, are more apt to occur after the anterior than the posterior operation. The best method is posterior suture gastro-enterostomy made within 4 inches of the origin of the jejunum; the Murphy button makes the most perfect opening, but is apt to be retained in the stomach; the McGraw ligature is very safe, and a fine opening is secured—it is particularly indicated in cancer and by the anterior operation; by suture a large opening can be made. All these methods give good results. In a series of 238 gastro-enterostomies for all causes performed by Mayo and his brother there was a mortality of 25 per cent. in malignant cases and 7 per cent. in non-malignant cases; 6 per cent. of the cases required a secondary operation. Other things being equal, the posterior method gave the most permanent results, but at a small increase of risk. In cancer early operation is requisite and diagnostic exploratory incision is necessary; very few of the 135 cases operated on for gastric cancer failed to live 12 months or more, and he is convinced that in 5 years as good results will be secured as in cancer of the breast; 60 per cent. are located in the movable pyloric region, and as the lymphatic supply is the same as the vascular the greater part of the stomach can be removed and the remaining portion employed for a gastro enterostomy; the operation can be made nearly bloodless by tying the four blood vessels as in a hysterectomy; wound inoculation can be prevented by severing the tissues with the cautery; by suturing the edges, distal to the clamps, the gastric and intestinal cavities need not be opened, and after permanently closing these openings a healthy portion of the stomach may be used in performing the gastro-enterostomy in the usual way.

#### DISCUSSION.

The discussion was opened by Dr. A. J. Ochsner of Chicago, who said that the differential diagnosis between chronic ulcer and gallstones is often difficult, but not important, as surgical intervention is indicated in either case. The examination of the interior of the stomach is not necessary, as drainage is the indication, not excision of the ulcer. There is a certain class of cases often diagnosed as gastric ulcer in which the appendix is at fault, not the stomach. The symptoms are referable to the stomach, but the pain is found to occur when pressure is made over the appendix. Some cases of locomotor ataxia may cause confusion. Neurasthenia may be secondary to gastric ulcer, so that the latter is not to be excluded if the former be present. The presence of a tumor is not a contraindication to operation; he has seen the removal of benign tumors give relief. The desire for food is not a sure sign in the differential diagnosis between cancer and ulcer; the decomposition of food in the dilated stomach, especially after hemorrhage from ulcer, may cause marked anorexia. The indication in chronic ulcer is clearly gastro-enterostomy, and the operation must be made at the most dependent point of the stomach to prevent regurgitation of intestinal fluids with the resulting vomiting. In the diagnosis the excess or absence of hydrochloric acid must not be relied on. He thinks the suture will prove the favorite method of operation, some method similar to that of Mikulicz. He favors the McGraw ligature and the anterior operation. In cancer the operation must be early. More cases are constantly coming to operation on account of the steadily increasing success of gastric surgery. The operation of gastrectomy after ligating the vessels and using clamps, as Mayo mentions, is comparatively simple, and is steadily gaining in favor.

The paper was also discussed by Drs. Stamm of Freemont, Hamilton of Columbus, Peck of Youngstown, Dickenson of Ashtabula, Sawyer, Allen, Parker, Hoover, Lowman, Biggar, Crile, Scott, Bunts, Rosewater, and House, of Cleveland.

Dr. Mayo, in closing the discussion, thought that medical means should certainly be first tried, but the trouble was that after so many medical cures relapses occurred. As to the efficiency and limitations of the surgical relief, accurate prognosis is not yet possible, but the results are most encouraging.

## Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Herpes Zoster.

The local treatment of herpes zoster, according to the *Encyc. Med. and Surgery*, consists in protecting the parts from injury and infection and to relieve the pain. For the latter symptom the following is recommended:

| | | | | |
|---|---|---|---|---|
| ℞. | Morph. sulph. | gr. v | | 30 |
| | Pulv. camphoræ | gr. xx | 1 | 30 |
| | Pulv. zinci oxidi | ℥i | 30 | |

M. Sig.: Dust on the affected area, cover with cotton, and bandage.

Or the following may be substituted:

| | | | | |
|---|---|---|---|---|
| ℞. | Morph. sulph. | gr. x | | 65 |
| | Collodii (flexible) | ℥i | 30 | |

M. Sig.: To be painted over the affected areas.

The galvanic current, applied along the course of the nerve, may be advantageous in giving marked relief from the pain.

Internally the following may be prescribed if the pain becomes so severe as to require an anodyne:

| | | | | |
|---|---|---|---|---|
| ℞. | Morph. sulph. | gr. 1/8 | | 008 |
| | Phenacetini | gr. ii | | 12 |
| | Quininæ sulph. | gr. i | | 06 |

M. Ft. cap. No. i. Sig.: One such capsule every four hours.

The phosphide of zinc, given in doses of one-third (.02) of a grain and repeated every three hours, is strongly recommended. For the neuralgia persisting after the eruption has disappeared, quinin, iron, strychnin and arsenic are of value.

### Fever Diet for Children.

Augustus Caillé, in *Post Grad.*, recommends a so-called "fever diet" in all febrile conditions in children. The food should be semisolid, so as not to overtax the feeble digestion or leave a large residue in the intestine for decomposition which would favor autointoxication or local irritation.

He recommends an exclusive milk diet for infants up to 8 months; also in typhoid fever, in acute and chronic Bright's disease and in acute pyelitis and scarlatina of children. In older children he prefers to add gruels and farinaceous and aromatic waters to the diet list. Boiled and cooled water should be offered freely to favor excretion and elimination by skin and kidneys. In older children who no longer take the bottle, food may be selected from the following list: water, toast water, farinaceous water, gum arabic water, egg white in water, peppermint tea, imported ginger ale, black tea, milk, matzoon, kumiss, buttermilk, whey; sterilized, pasteurized, peptonized milk, malted milk, beef broth, mutton broth, chicken broth, Mosquera's beef jelly, soups, gruels, cornstarch pap, pea soup, burnt flour soup, eggnog, somatose in peppermint tea, custard, ice cream, water ices, orange or pineapple juice and unfermented grape juice.

Milk is contraindicated, according to the author, in dyspeptic and inflammatory diarrheas and in cases of milk idiosyncrasies; also in typhoid cases accompanied by marked tympanitis. In such conditions some of the foregoing preparations may be substituted.

Rectal feeding is advised when food is not tolerated by the stomach or after an injury or operation on the stomach. It must also be employed where there is inability to swallow or in gastric ulcer, in incessant vomiting or in the insane. He then states the usual technic of rectal feeding. The fluid should consist of milk or gruel with egg, whiskey or peptonized food in watery solution. Children will usually retain from two to eight ounces. He further states that too much must not be expected from rectal alimentation on account of its little influence in counteracting the pernicious action of bacterial products or toxins on the nerve centers.

#### DIET IN CONVALESCENT STAGE.

The author recommends in cases of breast and bottle-fed infants, a gradual return to the food of the child given in health; and for older children, in addition to their milk, some of the following articles may be given:

Well-cooked cereals, cornstarch pap, bread pudding, scrambled eggs, calf's-foot jelly, beef jelly, milk toast, sponge cake, apple sauce, baked apples, scraped meat, bread and zwieback.

### Migraine.

Rachford, in *Med. News*, states that the treatment of migraine, in order to be successful, must be continued for many months, and the success of the treatment depends to a great extent on the simplicity and palatability of effective medication. He recommends the following combination:

| | | | | |
|---|---|---|---|---|
| ℞. | Sodii sulph. | gr. xxx | 2 | |
| | Sodii salicylatis (from wintergreen) | gr. x | | 65 |
| | Mag. sulph. | gr. l | 3 | 30 |
| | Lithii benzoatis | gr. v | | 30 |
| | Tinct. nucis vom. | gtt. iii | | 20 |
| | Aquæ destil. q. s. ad | ℥iv | 120 | |

M. Sig.: To be charged with carbonic acid and one-quarter to one-half glass to be taken in the morning on rising, one-half an hour before breakfast.

He recommends that the foregoing combination be made up in large quantities and sent to a mineral-water factory and charged with the gas and placed in small-sized bottles. Given after this fashion the author states that this medication may be continued for weeks or months without losing its therapeutic value or producing disgust on the part of the patient. If this combination proves to be too much of a laxative one of the following combinations may be used in its stead:

| | | | | |
|---|---|---|---|---|
| ℞. | Sodii sulph. (gran.) | ʒii | 8 | |
| | Sodii phos. (gran.) | ʒi | 4 | |
| | Sodii salicylatis | gr. x | | 65 |
| | Tinct. nucis vom. | gtt. iii | | 20 |
| | Aquæ destil. q. s. ad | ℥iv | 120 | |

M. Sig.: To be taken each morning on rising, one hour before breakfast; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Pot. bicarb. | gr. xx | 1 | 30 |
| | Sodii et potassii tartratis | ʒi | 4 | |
| | Sodii salicylatis | gr. v | | 30 |
| | Tinct. gent. comp. | ʒiv | 15 | |
| | Aquæ destil. q. s. ad | ℥iv | 120 | |

M. Sig.: To be taken in the morning before breakfast.

In the early part of the treatment the author recommends the administration of sodium benzoate, sodium salicylate or cannabis indica. The first preparation may be given in doses of twenty grains each (1.30) after lunch or dinner administered in peppermint water or some carbonated water. If sodium salicylate is preferred, it should be given in capsules in three to five grain (.20-.30) doses after lunch and dinner.

In children salol may be substituted, or in some cases salicin.

Cannabis indica is of great value, given in quarter-grain (.015) doses three times a day, in controlling the paroxysms of migraine and may be continued, if necessary, for three or four weeks, until the patient becomes accustomed to the siphon treatment. It may, if thought advisable, be combined with sodium salicylate or salol. All medication, except the siphon, should be discontinued after three to six weeks, unless, perhaps, it is necessary to give an intestinal antiseptic, in which case a one-grain salol coated pill of potassium permanganate is taken three times a day after meals, or in its stead the following more preferable combination:

| | | | |
|---|---|---|---|
| ℞. | Sodii sulphocarbol. | gr. v | 30 |
| | *Potassii permangan.* | gr. i | 06 |
| | Beta-naphthol | gr. i | 06 |

M. Ft. pilula No. i. Sig.: One such after meals and at bedtime.

To make a convenient carbonated draught the following may be used:

| | | | |
|---|---|---|---|
| ℞. | Sodii salicylatis (wintergreen) | ʒii | 8 |
| | Sodii phos. (dry) | ʒiv | 15 |
| | Sodii sulph. (dry) | ʒx | 40 |

M. Sig.: One teaspoonful to be taken in a glass of seltzer water on rising.

In children too young to take the charged combination the following combination is recommended by the author:

| | | | |
|---|---|---|---|
| ℞. | Sodii sulph. | ʒiiss | 10 |
| | *Mag. sulph.* | ʒv | 20 |
| | Lithii benzoatis | ʒii | 8 |
| | Elix *taraxaci* | | |
| | Aquæ destil., āā | ℥iii | 90 |

M. Sig.: One tablespoonful before breakfast for a child of eight years.

If the patients become, for any reason, nauseated by the use of this siphon method of treatment, dilute nitromuriatic acid is recommended after meals and cascara sagrada or the compound licorice powder at bedtime. After substituting these preparations for one week the charged preparations may be again taken.

### Acute Colds.

In cases of acute colds, accompanied by pharyngitis, the *Encyc. of Med. and Surg.* recommends an application of silver *nitrate grains fifteen* (1.00) to the ounce (30.) of water or the following combination:

| | | | |
|---|---|---|---|
| ℞. | Glyceriti acidi tannici | ℥ii | 60 |

Sig.: *To be applied locally three or four times daily; or:*

| | | | |
|---|---|---|---|
| ℞. | Menthol | gr. iii | 20 |
| | Liq. petrolati | ℥i | 30 |

M. Sig.: Apply locally.

As an inhalation the following combination is recommended:

| | | | |
|---|---|---|---|
| ℞. | Spts. chloroformi | m. v | 30 |
| | Menthol | gr. iii | 20 |
| | Tinct. benzoini co. | ℥i | 30 |

M. Sig.: One teaspoonful to be floated on a pint of hot water and inhaled twice daily.

Internally the following is of service:

| | | | |
|---|---|---|---|
| ℞. | *Codeinæ* sulph. | gr. iii | 20 |
| | Glycerini | | |
| | Syr. simplicis, āā | ʒii | 8 |
| | Sol. pot. citratis q. s. ad | ℥iii | 90 |

M. Sig.: Two teaspoonfuls every three or four hours.

### Children Predisposed to Phthisis.

McConaghy, in *Internat. Med. Mag.*, recommends, in the management of children predisposed to tuberculosis, that:

1. On rising, a glass of hot or cold water should be taken.
2. Breathing and other exercise in a well-aired room.
3. A regular time for stool immediately after exercise.
4. Cold bath with vigorous rubbing, upward, of the body.
5. A play of one hour in the sunshine every day.
6. Encourage proper carriage of the body, chest upward and forward, *abdomen drawn in* and arms hanging loosely.
7. Cultivate habit of breathing on the street, and breathe through the nose.
8. Sleep on hard bed and without a pillow.
9. Limit the child's studies.

## Medicolegal.

**Physician Must Show Compliance with Statute.**—It is now settled, the Court of Civil Appeals of Texas says, in the case of Wooley vs. Bell, that a physician can not recover for professional services unless he shows compliance with the statute of this state (Texas) regulating the practice of medicine.

**Milk-Supply Law Upheld for Bacteriologic Reasons.**—The Court of Appeals of Kentucky says, in the case of Sanders vs. Commonwealth, that the development in the science of bacteriology in recent years has conclusively proven that the microbe is a most potent agent in the propagation of contagious diseases, and that there is no more favorable element for their absorption, growth and development than milk, and that milk contaminated by their presence communicates diphtheria, typhoid fever, tuberculosis, and other kindred diseases, to human beings, especially to the young. And it is a matter of common knowledge that the conditions usually prevailing around places where "still slop" is produced are also highly favorable to the development of many forms of bacilli. The heat, dampness and fermentation—all essential elements in the production of still slop—are favorable to germ growth. So that it may be fairly assumed that the general assembly, in *the enactment of a statute prohibiting the sale of milk from* animals fed on still slop, had sufficient information to justify the belief that such milk had ample opportunity to become impregnated with elements dangerous to the public health. Nearly every police regulation affects to some extent property rights, and, while this power can not be made the excuse for oppressive and unjust legislation, the courts are not permitted to say that the legislature may not enact laws apparently necessary for the public health. Wherefore, the court reaches the conclusion that it has no power to hold that the general assembly did not have under the "police power" authority to enact the statute mentioned.

**Practicing Medicine.**—In Springer vs. The District of Columbia, where the Court of Appeals of the District of Columbia affirms a conviction of practicing medicine and publicly professing to do so without first having obtained a license so to do in the manner required by law, the court says that the statute not declaring what specific acts shall constitute "practicing medicine," or what it is to "publicly profess to do so," it is for the courts to determine whether the facts proved in a particular case bring it within the terms of the statute, taking these in the sense in which they are commonly understood. Here it appeared from the evidence that the party proclaimed himself an expert in the treatment of alcoholism, and had several patients. He furnished the remedies and employed licensed physicians to take immediate charge. These gave his remedies, and the only discretion exercised by them was in respect of the frequency of the doses, and of any complication that might ensue. In other words, professing knowledge of the science of medicine, he obtained patients, diagnosed their cases, decided that they were suffering from a malady for which he had discovered or compounded a remedy, prescribed and furnished that remedy, and employed other physicians to take immediate charge of the patients and administer the same. Selling his compound to such persons as he might examine and pronounce fit subjects of medical treatment was "practicing medicine" as much as if he had given them, instead, an ordinary prescription that could be satisfied in any regular drug store. The fact that he registered at a hotel as "Dr." would not be sufficient proof of a violation of the statute, but it was admissible to show, in connection with other evidence, that he held himself out as a practitioner.

**Against Compulsory Physical Examination—as to Urine.**—In Austin & Northwestern Railroad Company vs. Cluck, a personal injury case brought by the latter party, the Supreme Court of Texas considers, as a practically new question, the authority of the court to require the party suing in such a case to submit to a physical examination by a committee to be appointed by the court. It says that the right to have such examination is supported by the greater number of decisions of the courts of the states of this Union and by the text writers. But it is of the opinion that the fact that no such examination was ever authorized by a court at common law in England is conclusive that those courts had no authority under the common law to make such order. It says further that the provisions of the constitution and statutes of Texas with regard to the practice and jurisdiction of courts are antagonistic to the spirit and purpose of such proceedings. The constitution secures every citizen of the state against any seizure or search of his person which is not plainly authorized by some law of the state. Whether, under the constitution, the legislature might authorize the physical examination of a party to a suit, is not determined. The legislature has not only failed to provide for a physical examination of parties, but has actually repealed from the common law in the state the only proceeding that bore the slightest resemblance to it, namely, the right of view, by which a party sought to have his witnesses examine the premises to qualify them to testify. And it deems it sufficient to say for the courts of Texas that the authority to order such an examination and force a party to submit to it is found neither in common law nor in the statute laws of the state, and therefore does not exist and can not be exercised by the courts of Texas. It may be true that evil practices by plaintiffs in these cases have grown up, but it is equally true that to establish such a rule of practice would place in the power of defendants in damage cases the means of annoying plaintiffs, and of intimidating the most worthy of the complainants in such suits. Then, at the trial of this case, after the testimony of physicians who had treated the party suing for his injuries had been introduced, and he had himself testified as to his injuries and the circumstances under which he received them, the attorney for the railroad company propounded to him this question: "Are you willing, in the presence of some reputable person, or by yourself, and subsequently to be supported by your affidavit, that it is urine voided by you into a vessel which is absolutely free from any foreign matter, to furnish a specimen of your urine, voided under the circumstances stated, to a committee of competent physicians to be appointed by the court, so that an analysis of that urine may be made?" The Supreme Court holds that an objection to this was properly sustained. It says that the same objections apply to this procedure as to that which sought a physical examination of the party suing. The court could not enforce such an order without taking possession of his person and exercising coercive power to compel him to perform the act. Again, the Supreme Court says that the reason for refusing a physical examination of the party suing is not that the other party is not entitled to have the benefit of the evidence, but because the court has no power to force him to submit to such an examination. He has a right to submit or refuse, but, in case he should refuse, the party sued is entitled to have that fact go to the jury, to be considered by them in determining on the credibility and sufficiency of the testimony on which he seeks to recover. If the jury should believe that the refusal showed a purpose to conceal the truth, they might take the fact into account in weighing the evidence. If a satisfactory reason should be given for the refusal, and other evidence were sufficient, the refusal would not defeat a recovery. The suggestion that the court might enforce its order by refusing to submit the case to a jury is not sound, for in this state a party is entitled to a trial by jury whenever he produces evidence which shows *prima facie* a right to recover. In case of unreasonable refusal to allow examination, the court could and should set aside the verdict, unless the evidence satisfactorily established the right.

1 *The Mortality of Appendicitis. Frederick S. Dennis.
2 *The Relation of Proteids to Edema in Marantic Children; with Urinalysis in Infantile Diarrhea. Palmer A. Potter.
3 *Diagnosis of Gall-bladder Diseases. J. Thompson Schell.
4 *The Diagnostic Value of the Roentgen Rays. Charles L. Leonard.
5 *The Value of Climate in Genito-urinary Tuberculosis. W. H. Prioleau.
6 Seasickness. William F. Waugh.

1. **Appendicitis.**—Dennis holds that the average mortality of appendicitis under medical treatment is about 16 per cent., with 30 per cent. of relapses, while with diffuse suppurative peritonitis it is almost uniformly fatal. On the other hand, the mortality in appendicitis in all cases under surgical treatment is about 4 per cent., with no relapses, and in diffuse suppurative peritonitis the mortality given by the statistics is from 31 per cent. to 90 per cent. In 11 consecutive cases here reported the mortality was 0. He comes to the conclusion that after thirty-six hours, if the case is not improving, it should be operated on at once, and in other cases where the attack runs a favorable course the interval operation should be performed. The plan of allowing simple catarrhal cases which are doing well within thirty-six hours to recover without intervention, and prompt operation after thirty-six hours, when the cases are not doing well, gives the best prospects. The pendulum, he thinks, has swung too far toward indiscriminate operation. In his last 119 cases up to April, 1903, the mortality, irrespective of operation or any plan of treatment, was a little over 1.5 per cent. In cases treated without operation in which the attack was a mild catarrhal one, and the patient not operated on during the attack, the mortality was 0. In many cases the appendix was subsequently removed owing to repeated attacks, without any mortality. A gangrenous appendix rupturing into the peritoneal cavity with general peritonitis occurred in 11 of his cases. In cases where there was acute perforative appendicitis with gangrenous appendix in a circumscribed abscess cavity, the mortality was 7 per cent. Two fatal cases out of the 119 were hopeless from the start, but were operated on as offering the only chance. Without these the whole series gives no mortality. He would impress on the family physician the fact that appendicitis is essentially a surgical disease and early operations are almost always successful. The mortality can only be reduced by the hearty co-operation of the physician and surgeon.

2. **Infantile Diarrhea.**—Potter has sought to settle the question whether the kidneys are involved in the summer diarrhea of infants. He concludes that acute diarrheas—not protracted cases—are not accompanied by kidney involvement. Alcohol, therefore, is not injurious in this condition if it is necessary as a stimulant. Edema in the diarrhea of marantic infants is a bad sign, but not necessarily fatal, and it is not due to the heart or kidneys. The bad general condition is best treated by disregarding the diarrhea and increasing the strength of the proteid nutrition.

3. **Gall-Bladder Diseases.**—Schell's article is a general review of the diagnostic points of gall-bladder diseases.

4. **Calculus and the X-Rays.**—The special point of Leonard's paper is the use of the Roentgen rays in diagnosing renal and ureteral calculus. From a study of 300 cases referred for examination, he finds that calculi were found in 86, or about 28 per cent. In 46 of these cases, or over 50 per cent., the calculi were in the ureters. In 19 cases the patients passed the calculi after expectant treatment had been suggested by the Roentgen examination. Positive diagnosis was confirmed in all the cases except 5, and in these the operation was performed late, and it is possible that the calculi had passed away. He advises repetition of examination if the operation has been delayed, to make sure of the actual condition, and as to whether or not the cases still require operation. The negative diagnosis has been found as accurate as the positive. Where the Roentgen method shows no calculi present in the kidney, in-

cision, he thinks, is not justified unless some other macroscopic pathologic lesion is present. In favorable cases, that is, patients weighing under 140 pounds, detail can often be obtained of the soft tissue structures that will suggest some condition other than calculus that is present. Thus displaced kidneys and pus collections have been observed. His technic in calculus diagnosis is based on the axiom that where shadows less dense *than the least dense calculus are obtained,* no calculus should escape detection. He uses a self-regulating tube, which maintains itself at a low vacuum steadily during the entire exposure. The coil or source of energy must produce a large volume of Roentgen rays of low penetrating quality. The method has already rendered operation unnecessary in a number of cases, increasing the value and efficacy of operation, while lessening its dangers and minimizing the amount of operative lesion.

5. **Genito-Urinary Tuberculosis.**—Prioleau favors moderate elevation for cases of this class. There are cases that respond most readily to treatment at sea level. At no time should a patient with kidney tuberculosis be sent to an extreme altitude, as increased altitude adds to the work of the already inflamed kidney and does away with the benefit otherwise obtained. Moderate elevation is favorable to the patient, as he can return home with the least probability of its reappearing. Climate alone is not the only thing; he mentions over-feeding as one of the dangers in these cases. We must rely on hygiene and diet, and as an adjunct, use antiseptics and sedatives, always selecting a suitable climate for the patient the same as if his lungs were diseased.

13 *A Simple and Accurate Method of Examining the Stools for Gallstones and Other Solid Bodies. Howard Lilienthal.

7. **Rheumatism in Childhood.**—Winters holds that rheumatism is due to the absence of potassium and sodium salts in the tissues. To supply this the alkalies in organic combination as produced by nature in fruits and foods, especially the vegetable acids, are required. He notes the obscure symptoms of rheumatism in children and its importance as bearing on cardiac involvement. To meet other physiologic requirements, animal food is requisite, but it should not exceed the needs so as to lead to over-stimulation and defective metabolism. To meet the rheumatic condition he would begin with calomel followed by rhubarb and soda, the latter to be persisted in as long as the tongue is furred, the soda to be given in 20-grain doses, t.i.d., before eating. Milk should be the sole food while the symptoms exist. The first extension of the diet should be the addition of a strained cereal, which should be given without the child's knowledge and should be taken without sugar. When animal food is added it should be in the form of meat, not broths or beef juice. Vegetable soups, bean, tomato, etc., are nutritive and appetizing. When all rheumatic manifestations have been dispelled, animal broths *on cereals* serve for stimulating the appetite. When the tongue is clean and the rheumatic symptoms banished, begin in due succession with strained cereals, *vegetable* soups, cereal as a vegetable, with butter and salt, baked potato, bread, green vegetable and fruit. The failure in the dietetic management in the past has been in the excessive use of broths, sugars and sweets, the use of alcohol, and the withdrawal of fruits and cereals.

8. **Fractures Involving the Joints.**—Gibney's paper, as he expresses it, is a plea for plaster of paris as a dressing for fractures, and a comparison of joint injuries from trauma and those from disease, the harmlessness of the one and the ravages of the other. He favors a careful study of the mechanism of the joints in setting the limb and a knowledge of the muscles involved, plaster applications to be based on these. The normal tendency of all joints damaged by trauma is toward flexion deformity, and it is important to recognize this factor, as, if left too late, it may be difficult to remedy. His attention has often been called to the too-shortened condition of the tendo Achillis due to the foot being in many cases put up in moderate extension. The fact of the unpopularity of plaster of paris he thinks is largely due to the little instruction that students receive in regard to its application, and the carelessness with which it is applied. He speaks against passive motion after fractures.

9.—See abstract in The Journal, xli, p. 1,041.

11. **Anesthesia.**—Robertson has employed hyoscin hydrobromate in connection with ether anesthesia in 57 cases of abdominal and other operations in adult women and with excellent results. He usually gives .01 of a grain of hyoscin hydrobromate hypodermically half an hour before the beginning of ether inhalation, causing dryness of the mouth, thirst and dilatation of the pupils, at which time ether is administered. The administration causes little secretion of mucus, the patients are less anxious, there is a tendency to sleep after recovery from the anesthesia, which is more rapid as a rule than when ether alone is given, and in no case was there any severe or prolonged after-vomiting. It was altogether absent in at least half the cases. In 55 cases the patient was absolutely quiet during the administration. In none of the cases was there any bronchitis following the ether or other respiratory disturbances. The hyoscin hydrobromate, he thinks, acts by counteracting the over-stimulating effect of ether, decreasing the amount of mucus, which obstructs respiration, etc. If it proves to be free from danger it will be a valuable aid in the administration of ether.

13. **Examining the Feces.**—Lilienthal fastens to a wire loop a bag of at least two thicknesses of gauze dressing or mosquito netting, which he places in the water closet receptacle as a sieve so that the free turning on of the water after defecation washes away all except the solid constituents and thus reveals, without the usual objectionable incidents of straining of the feces, the presence of gallstones, etc.

19 The X-ray Technic of Dr. H. Albers-Schonberg. Eugene R. Corson.

14. **Induced Radio-activity and Its Therapeutic Possibilities.**—Tracy found by experimentation that normal salt solution was one of the best substances for the manifestation of induced radio-activity. He inserted into a bottle containing the solution two hermetically sealed tubes of radium bromid, leaving them for twenty-four hours, and then let the salt solution stand in the rack for twenty-four hours more. He then tested the fluid and gives the results in skiagraphs produced by its influence. It has suggested to him that the property radium possesses of imparting its activity to other fluids, for example, normal salt solution, seems to offer the hope that in this way it may be therapeutically administered, and the fight against bacterial disease affected through the agency of the fluid and lymph circulation and internal secretions. "Radium fluid," it is true, only holds this property temporarily, but the manufacture of it is so simple that when radium is more available than it is at present there will be no difficulty in keeping up the supply. The emanation will escape rapidly when the patient drinks the water, but the "active matter" which is produced, according to Professor Rutherford of McGill University, will remain with the water and produce radiations for a couple of hours, after which its intensity becomes very small. Tracy suggests that in this "radium fluid" we may have the

means of striking at the root of certain diseases, such as diphtheria, tuberculosis, typhoid, etc., also fermentative gastrointestinal indigestion, with its attendant auto-intoxication. Its local employment is also suggested. While the results may not realize these anticipations, it is certainly worth while, he thinks, to try the experiments.

17. **Milk Modifications.**—Edsall and Fife have examined various milk-mixtures, estimating the fat and proteid as agreeing with theories, and found that in the first series of home modifications, made of certified milks and creams by persons of intelligence, the proteid content was satisfactorily accurate, the widest variations from the standard being small, .2 of 1 per cent. The fats varied widely, with errors from .8 to 1.6 per cent. in this small series. (The article is to be concluded.)

18. **Tuberculosis.**—This installment of Maher's article is entirely given up to the reports of cases.

20.—See abstract in THE JOURNAL of January 9, p. 118.

21. **Causes of Death.**—Solis Cohen notices the difficulties appertaining to the judicial determination of the cause of death and suggests a jury of experts, 5 to 7, selected to meet the conditions in question. In deciding as to the cause of death they should not be required to reach a unanimous verdict, but a majority and minority report; several minority reports or individual jurors' reports in extreme cases might be handed in. Of couse, the unanimous verdict would be the one to be preferred, but this method would be more apt to bring about the truth and aid justice.

22. **Uncinariasis.**—Warfield, from his observations in Georgia, concludes that there is a direct relation between the so-called ground itch and uncinariasis, but he does not assume that the parasite necessarily finds its way to the blood directly through the skin, while he can not deny this possibility after Loos' conclusive experiments. The mode of infection, he believes, is by children scratching the itching surface and introducing the embryo afterward by the fingers into the mouth. Uncinariasis is one of the commonest diseases of the south, and its introduction by any other method in children is improbable. Its prevention lies in the use of latrines easily cleansed and disinfected, and thoroughly closed from access by barnyard fowls, etc., and the general education of the medical profession in the country districts as to the nature and prevention of the disorder.

23. **Epileptic Insanity.**—Wherry reports a new method of treatment inaugurated in the Clarinda State Hospital of Iowa, in which, instead of the bromides, the vasodilator drugs are employed and with most excellent results. The fundamental principle is the combination of vasodilating drugs with saline cathartics and an alterative, the principal ingredients to be left to the judgment of the attending physicians. The results are significant in view of the theory that the disease may be due to a vasomotor spasm. He tabulates his experience, showing a number of fits before and after treatment which seemed to indicate the value of the method.

25. **The Ithaca Typhoid Epidemic.**—Coville gives a brief history of the progress of the Ithaca epidemic and its causes, calling attention to certain peculiar features, among which he enumerates the absence of sure causal proof, the sharp onset and abrupt termination of the epidemic, the large number of typical cases and the cyclic recurrence of the symptoms after fourteen days' interval. Many cases were severe and septic, but there was a relatively small number of relapses in the typical ones. The drinking of city water seemed to be the most obvious cause; the milk supply had not been infected. Infection by other sources was not observed. The death rate was much higher in students than among the townspeople; physicians and trained nurses were practically immune. The total death rate under the conditions was low, 6.6 per cent. All the physicians had practically the same average. The number of cases, over 1;300, and probably over 1,400, was notable.

*January 7.*

26 *Obstetrical Nursing. A. Worcester.
27 *Some Questions Relative to Extrauterine Pregnancy, with Especial Reference to Tubal Abortion. Malcolm Storer.
28 *Typhoid Fever in Children. (Concluded.) Adolf Baginsky.
29 The Finsen Light Cure. H. John Stewart.

26. **Obstetric Nursing.**—Worcester advocates the trained obstetric nurse with an education that is required for the skilled midwife, though it is not expected that she will act as such. He thinks the more training the nurse has the less likely she will be to assume responsibility of obstetric cases. The obstetric nurse should be expected to exercise precautionary surveillance during pregnancy, to manage the first stage of labor, to recognize any abnormal occurrence and to be able to conduct a normal labor, to apply appropriate preliminary treatment in emergencies, and, in confinement, to care for both mother and baby intelligently. A hospital training alone will not fit the nurse for home obstetric work. She has had no experience with anxious husbands, terrified children and cranky servants. The modern hospital nurse often distorts and magnifies the normal condition into an unnatural and extraordinary experience.

27. **Extrauterine Pregnancy.**—The typical classical symptoms of extrauterine pregnancy are not usually present, according to Storer, and he gives illustrations of this fact. He places no special importance on symptoms of anemia, expulsion of decidual tissue and amenorrhea, which may all occur without it. In fact, the condition itself may be symptomless. Of course, the further advanced the condition the easier the diagnosis becomes. The symptoms he considers of chief importance are pain and anomalous escape of blood from the uterus. The pain is different from that of ordinary menstruation, short-lived, often stabbing, not colicky or anything like as severe as that due to rupture of the tube. It may be accompanied with nausea without vomiting. There is more or less protracted metrorrhagia, as a rule. Patients are apt to pay little attention to this pain, thinking it due to ordinary miscarriage and so on, and do not come under observation until some weeks later, and then on account of the pelvic peritonitis that results. In his experience ectopic pregnancy is not so apt to occur exclusively in multiparæ after a protracted secondary sterility. In 41 per cent. of his cases the patients were primiparæ. As regards treatment he asks five questions: 1. Whether a case seen immediately after rupture—in collapse and acute and profound anemia—should be immediately operated on? He favors immediate operation. 2. With a diagnosis of probable unruptured extrauterine pregnancy is it better to operate at once or wait until the diagnosis is certain? He thinks a reasonable probability implies operation. Certainty generally comes only with rupture. 3. Given a tubal abortion a month or two before the patient is seen, is it better to operate, supposing a mass can be felt, or allow nature to take care of it? He thinks nature will usually take care of it after a longer or shorter period of pelvic peritonitis with pain if nothing worse, but it is more surgical and certain to clear out the pelvis in such a way as to remove the old clots, break up adhesions, patch up the tubes, etc. 4. Whether it is better to operate from above or below? He thinks that undoubtedly surgeons of greatest experience in vaginal celiotomy may prefer that method, but he has never been one of them, and is not likely to become so. As regards the fifth question, what to do with extrauterine pregnancy at full term, he has had no experience. The decision as to how to treat the placenta is about as difficult a one as the surgeon has to make. Of course, if the main blood supply can be cut off, it simplifies matters, but even then it is by no means easy, and those who have removed the placenta in cases where the child is alive describe it as a nightmare. Another point he makes is in regard to the after-history. He thinks extrauterine pregnancy may readily be followed by a

normal one, though the possibility of a second abnormal pregnancy must be borne in mind. In conclusion he says he has left the question of diagnosis in a rather unsatisfactory condition, but can not help it. In many cases a positive diagnosis is out of the question. The let-alone-and-wait plan will never work. If you do not find an extrauterine pregnancy there will probably be some other trouble that will be bettered by operation.

28. **Typhoid Fever in Children.**—Baginsky's paper is concluded in this issue, describing the symptoms, abnormal forms, complications, diagnosis, prognosis and treatment. The respiratory organs are always more or less involved. The nervous symptoms may be severe, though usually not so pronounced as in adults. Digestive abnormalities are prominent. The urine is scanty and of high specific gravity. The roseola is rarely lacking. The shortest forms of typhoid often occur in children and are characterized by slight gastric disturbance, somewhat typical typhoid tongue, moderate fever with evening exacerbations and positive urinary and blood reactions, but the most significant thing is the occurrence of other cases at the same time. Children are more predisposed to relapses. Complications have been recently shown to be generally due to the typhoid bacillus, especially respiratory complications, which are perhaps the most frequent. The diagnosis is easy as the case progresses, though the difference between typhoid and miliary tuberculosis is often difficult. The prognosis is usually favorable, though affected seriously by pneumonia and parotitis or other infectious diseases. As regards treatment, he remarks that children with typhoid can not stand very cold baths, and the permanent lukewarm bath after the Riess method is principally to be recommended. The child is laid on a sheet which is spread out in a tub beneath the surface of the water and remains there for hours or days, according to the height of the fever. Children bear the cold pack well, and it may be well substituted for the cold bath. If possible, limit the antipyretic treatment to external methods, but if quinin is used it should be given in pretty good-sized doses. Salicylate of soda, phenacetin, etc., may be very cautiously used, but these remedies depress the heart's action and may become dangerous. Proper nursing is important. He does not restrict the feeding to milk, but all solid food is forbidden. Bouillon, wine, yolk of eggs with water, milk, somatose, and cornstarch preparations are among the foods that may be given. Diarrhea is best treated with bismuth or similar drugs, and intestinal hemorrhage with cold applications externally with cold nourishment and liq. ferri sesquichlorid (3 to 5 per cent.) or gelatin solution. The respiratory organs need especial attention, and in case of otitis media it is not wise to delay long before resorting to paracentesis of the tympanum. Hypnotics may be required and chloral hydrate is best. The bromids have little effect. If there is pus in the urine, urotropin is good, giving 15 to 24 grains per day to render the urine aseptic. Complications such as periostitis, decubitus, etc., must be treated on general surgical principles. During convalescence it is particularly important to watch carefully the action of the digestive organs. Great care must be used in passing from the liquid to a solid diet and particularly to a meat diet. It is not safe to give meat for at least a week after the temperature is normal.

30 *A Few Considerations on the Etiology and Pathology of Cutaneous Cancer. (To be continued.) A. Ravogli.
31 Diphtheria. E. W. Mitchell.
32 Gynecology in Lawson Tait's Old Home. Magnus A. Tate.

30. **Cancer.**—Ravogli does not consider skin diseases like eczema, psoriasis, lupus, etc., as pre-cancerous states. If they have any relation to the cancer it is only because they are concerned in the production of abrasions and diminish the vitality of the tissues, thus favoring the admission and development of the germs. The one form of pre-cancerous condition which he mentions particularly is the so-called pre-cancerous keratosis, which must be considered as the earliest superficial demonstration of the growth. He favors, as seen from the above, the parasitic theory, which he thinks is the only one supported by facts, and he can not believe that the pre-existing tissues can take on malignancy alone. The production of cancer can not, he says, occur solely from the mistaken place of a few epidermic cells. There must be some other reason. Another point in favor of the parasitic theory is the innoculability of cancer, which he thinks has been demonstrated. (The article is to be continued.)

*January 2.*

33 *The Acquisition of Tuberculosis in Infancy. E. W. Saunders.

*January 9.*

34 *Serum Therapy in the Treatment of Tuberculosis. Joseph B. Hardy.

33. **Tuberculosis.**—Saunders discusses the infection of tuberculosis, especially from cattle, admitting the possibility at least of skin infection, and rather favoring the opinion that alimentary infection is one of the most important methods of introduction of the germs in infancy. It seems, he says, that established facts as well as possibilities should compel admission that the bovine bacillus is virulent to man, and also a modified assent to Behring's statement. That alimentary infection in childhood is a prolific source of later manifestations of tuberculosis, especially in the bones, Saunders thoroughly believes. As regards the question whether bovine tuberculosis is less or more malignant in its course than infection from the human bacillus when introduced into the system, he thinks there is no evidence available to satisfactorily answer it. He has had one or two cases where he has suspected the communication of tuberculosis from one individual to another, but in these cases there was also the possibility of alimentary infection. He thinks the practical lessons are to pasteurize all milk given in the first quarter of infant life, when the permeability of the mucous membrane is so great. After that we should use a mixed diet, but raw or underdone beef and, above all things, smoked sausage should be prohibited to children.

34. **Tuberculosis.**—Hardy advocates the use of anti-tubercle serum. It is of greater value in early life than past the age of 30, and in acquired tuberculosis than that with hereditary predisposition. After the lung tissue has broken down and cavities formed it seems to do little good. No one need regard it as a curative agent like diphtheria antitoxin. He thinks the unfavorable impression of the profession about it is due to its improper use and the fact that it has been employed only as a last resort. In addition to the hypodermic treatment he uses, of course, other medicines where indicated.

35 *Personal Experiences in Angina Pectoris. M. B. Smith.
36 Preliminary Report of a Case of Morbus Addisonii. N. E. Aronstam.
37 *Traumatic Neuroses. Frank A. Ely.

35. **Angina Pectoris.**—Smith reports his own case and the success he has had with a carefully regulated life and the avoidance of irritation. He has found no drug or treatment that seems to do him any good, but a careful avoidance of strain and exertion, of people that irritate and annoy him, and of temper explosions, etc., has made life endurable. He has had no attack for a number of years.

37. **Traumatic Neuroses.**—The importance of these conditions and their connection with organic lesions are noted by Ely, who emphasizes the following points:

> 1. Nervous symptoms similar to those met with in traumatic hysteroneurasthenia may be noted as the result of sudden and intense mental strain, unassociated with traumatism. 2. Clinical experience and a few isolated postmortem findings indicate that microscopic lesions of the brain and cord may result from traumatism without external evidence of violence. 3. Although we know these minute lesions are often present, our knowledge of their effect is as yet insufficient to enable us to differentiate between cases in which they do or do not exist, and their possible presence does not necessarily influence our prognosis. 4. Hysteria must be looked on as a true disease, which may be brought on by traumatism, and which may bring more trouble into a home than a broken limb or a sprained back.

41 Tuberculosis of the Parotid and the Possibility of Infection Through the Tonsils. George B. Wood.
42 Treatment of Fractures of the Radius Between the Insertions of the Pronator Muscles. J. Rex Hobensack.

38. **Gastroptosis.**—From an observation of over 100 cases of gastroptosis, Steele and Francine conclude that in gastroptosis certain cases are relieved so promptly by external mechanical support, without other treatment beyond dietetic, that the downward displacement of the pylorus must be regarded as the primary or at least the principal factor in the causation of the symptom-complex. In their series the cases of this character showed a moderate diminution of HCl, were free from organic disease, and had no signs of dilatation or impaired motility. The symptoms were gastric fermentation, frontal headache, with sensation of dragging and lack of support in the abdomen. Gastroptosis may exist absolutely without symptoms. This is shown by the findings in the routine examination of other morbid states. Such patients were not benefited by external support. Gastroptosis may also form a part of the symptom-complex of other morbid states, such as gastric neuroses from nerve exhaustion due to overwork, gastric motor insufficiency, dilatation and passive gastric congestion from weakness of the cardiac muscle. Here the downward displacement of the pylorus is an important complication which is shown by the relief and comfort derived from mechanical support. That it is a complication, however, is shown by the fact that no considerable relief is obtained without treatment directed to the primary condition. The value of external mechanical support as a means of treatment is shown by the fact that all primary and uncomplicated cases recover completely under its use. Effectual mechanical support applied over long periods does not permanently restore the stomach to its normal position, as shown by examination in 18 cases, but the support of the stomach seems to produce some change, for it enables the organ to successfully perform its function in spite of a certain degree of displacement. These changes are probably compensatory. The larger part of the paper is devoted to a report of cases.

39. **Tubercle of the Pons.**—Potts and Spiller's case was examined after suicide. The symptoms indicated a lesion of the left side of the pons. The presence of paralysis of the lateral conjugate movement of the eyeballs toward the left made almost certain the diagnosis of a growth implicating the left half of the tegmentum of the pons. The diagnosis was confirmed by the necropsy. Spiller emphasizes the importance of this paralysis of the lateral associated movement of the eyeball in the clinical diagnosis as a sign indicating intrapontile tumor. He would hesitate to recommend operation for the removal of a pontile tumor with this form of ocular paralysis. Its absence, however, is no proof that the pons is not invaded, but merely that the posterior longitudinal fasciculus is intact.

55 *The Occurrence of the Colon Bacillus on the Hands. C. E. A. Winslow.
56 Protozoa in a Case of Tropical Ulcer ("Delhi Sore"). James H. Wright.

43. **Bacillus Tuberculosis.**—Wolbach and Ernst have studied the tubercle bacillus in various cultures, and remark on the variations of the form and staining reaction, greatest in the rapidly-growing cultures. They agree with Coppen-Jones that favorable media and free access to oxygen tend to branched and filiform forms. The only interpretation of the great diversity of form assumed under the most favorable conditions is that the bacillus is truly pleomorphic, and should be classed among the higher bacteria.

45. **Granules in the Red Blood Cells.**—Vaughan describes certain granular bodies observed in red cells in certain conditions which he considers can not be artefacts, as they do not increase on allowing the specimen to stand. They can not be due to alteration of the hemoglobin content of the cell because where they are most abundant the hemoglobin is normal in appearance and distribution. Experimental evidence tends to the probability that they are remnants of a nucleus that has disappeared throught a process of karyorhexis or karyolysis. Their importance depends on whether they are present in a large proportion of cells. When they are present in a larger proportion than normal in the circulating blood, the same value can be attached to them under certain limits as is given to the finding of nucleated red blood-corpuscles. An increase of the granular cells to 9 or 10 per cent. of the total number would indicate a marked departure from the normal, and would probably not occur in the absence of nucleated forms that later might reward the search. In secondary anemia, however, the high percentage of granular cells would be looked on as a favorable sign indicating a state of blood regeneration, whereas in pernicious anemia its prognostic value would be practically *nil*. The rise of blood count and the hemoglobin index would be more important. These granules are easy of recognition by the method described, that is, the use of Unna's polychrome methylene blue as prepared by Grübler, which shows not only these but nucleated cells. The facts would seem to warrant the notion that their determination must be of some value in the clinical study of the blood.

46. **Volume Index.**—This expression designates the size of the erythrocytes in comparison with the normal. Capps found that the cell volume is invariably increased in pernicious anemia, more so usually than the Hb content of the cell. This heightened volume index is a more constant and trustworthy sign of pernicious anemia than the increased color index. Moderate cases of secondary anemia show only a slight loss of cell volume, but if of high grade the cell becomes small and atrophic. In a small group of secondary anemias the low color and volume indices of chlorosis appear, but later the blood turns macrocytic with high volume and color values, a type which resembles that of pernicious anemia. In a large proportion of chlorotics the cell volume suffers as well as the Hb, though to a less extent. The volume is of great significance in the prognosis. Cases with a low volume index respond slowly to treatment, and the cell volume has as much to do with the improvement as the Hb content. In all anemias the color loss is greater and takes place more rapidly than the loss in volume. In recovery the volume is restored before the color. The Hb content of normal erythrocytes represents the point of saturation of protoplasm. When the color index rises above 1 we may assume a corresponding increase has taken place in the cell volume, excepting in jaundice, where the color test is unreliable. Supersaturation of the cell protoplasm with Hb probably does not occur, but the cell may lose its Hb without necessarily losing its volume. The volume seems to be chiefly altered by the influences affecting cell growth or degeneration. The large erythrocytes of pernicious anemia are probably young cells. Small cells may result from malnutrition of the bone marrow, as in chlorosis, or from actual degeneration, as in sepsis. The cell volume suffers very little change from osmotic influences, according to Capps' observations. Dropsy, cyanosis, hydremia following hemorrhage and jaundice (with some exceptions) do not materially alter the form volume of the cells. He has

never noticed the "acute swellings" described in dropsy, hemorrhage, jaundice and chlorosis. The volume of the individual erythrocyte is best obtained by using the centrifuge in connection with the hemacytometer.

**55. The Colon Bacillus on the Hands.**—In 111 persons examined by Winslow the colon bacillus was found on the hands in 10. In one experiment, children whose hands were especially dirty were taken, but in all the other cases the subjects were chosen at random. Excluding the selected children, 4 positive results were obtained from the hands of 48 children. Of 35 technologic students 2 gave positive results, of 16 servants and janitors 1 gave a positive result. It appears, then, that the colon bacillus was normally present on the hands of between 5 and 10 per cent. of the persons examined. This makes it easy to see how readily the typhoid bacillus may be transmitted by the hands of those affected with the disease or their attendants.

58 *Influence of the Leucocyte Count in the Decision for or Against Immediate Operation. E. S. Van Duyn.
59 Keratoconus. G. Griffin Lewis.
60 The Pathology of Asthma with Special Reference to Its Vicious Circle. G. N. Jack.
61 *A Plea for a More Conservative Treatment of Appendicitis. F. W. Higgins.

**57. Typhoid Gangrene of the Limbs.**—Ricketts gives the statistics of 134 cases reported, together with one of his own personal observation. He insists on early amputation, high enough to be above all the gangrenous tissue. Spontaneous amputation, as a rule, should not be encouraged except, perhaps, in a few cases in the aged, where both extremities are involved in dry gangrene, slow in development, and the debility is such that surgical anesthesia is contraindicated. If the line of demarcation is sharp and amputation can be done rapidly above the knee or ankle, without surgical anesthesia, spontaneous amputation should not be considered. Of the 134 reported cases, 100 were male and 34 female. There were 128 surgical and 3 spontaneous amputations, 3 not stated; 15 of both limbs, 41 of the right leg, 20 of the left leg, 15 of both feet, 18 of the right foot, 16 of the left foot, 5 toes, one hand and toes, 3 middle thigh, 3 of the upper thigh, 2 of the lower thigh, 3 both thighs, 30 dry and 2 moist gangrene, 112 not stated. There were 6 recoveries with operation, 1 with no operation; 34 deaths without operation; 22 deaths with operation and 12 unknown.

**58. The Leucocyte Count.**—Van Duyn has tabulated 50 consecutive cases, which he analyzes in his paper, reporting 2 in detail. He is inclined to consider a leucocyte count over 10,000 or 15,000 as high, below that as normal. If it is above 10,000 to 15,000 he would always advise immediate operation, however mild the other symptoms may be, especially if the leucocytosis seems to be increasing, but if other symptoms pointed strongly to the necessity of intervention, a low leucocyte count should not deter from operation. While it is of great assistance, the knowledge obtained from other signs and symptoms present loses none of its weight, and all should be carefully considered.

**61. Appendicitis.**—Higgins would treat most cases of appendicitis as medical, carefully watching them and operating when indications demand after careful, unprejudiced consultation. The interval operation should be recommended after a second attack.

74 *Studies on the Antagonistic Action of Drugs. H. D. Haskins.
75 *Blood Changes in Dementia Paralytica. A. R. Diefendorf.

**62. The Argyll-Robertson Pupil.**—Thomas discusses the physiology of innervation of the pupil and pupillary reaction, but comes to no positive conclusion in regard to the mechanism, as our knowledge of the sympathetic nervous system is too inexact. He is inclined to favor Langley's idea that the ciliary ganglia can hardly act as a reflex light center in these cases, as maintained by Marina. It would appear that he still thinks that possibly the evidence is in favor of a more central mechanism.

**63. Cerebral Tumors.**—From a study of 101 cases reported in the last five years, Woolsey concludes that more recent experience indicates that the sphere of operation for cerebral tumors has been extended to those parts of the cortex where tumors are accessible and localizable, that is, to the prefrontal, the parietal and occipital regions, in addition to the motor area. That the prognosis, both immediate and remote, is as good or even better than any operation for malignant growths in some other localities. It has improved with the improvements in localization and operative technic, and with the limitation of the radical operation to cases accurately localized. Palliative operation is indicated to relieve the symptoms where localization can not be accurately made or the tumor be removed, but exploratory operations are contraindicated. Practically all circumscribed growths are amenable to operation. The osteoplastic method should be employed and the most rapid and perfect technic, with complete asepsis.

**65. Tumors of the Sigmoid Flexure.**—Ewald here notices the tumor due to fecal accumulations and the malignant growths which may be confined to the sigmoid or extend upward from the rectum. In the latter case they should always be detected, but are sometimes overlooked. In many cases obstruction suddenly occurs with its characteristic symptoms. Often the physician will be led to believe he has a strangulation, volvulus or intussusception, when operation reveals a tumor. The neoplasm may grow into the lumen of the intestine, causing no thickening and being hardly possible to palpate. Such a growth may lead to no symptoms until suddenly obstinate constipation occurs, due to narrowing of the lumen, which becomes blocked. Such attacks may frequently recur until cathartics are of no use. The general condition is not affected as much as in other cases of acute obstruction. He mentions a case in which he diagnosed carcinoma of the sigmoid on account of there having been four attacks of constipation with pain, moderate distension of the abdomen and marked distension in the left iliac fossa, moderate pain in this region recurring at regular intervals, radiating outward from the sigmoid, the rectum negative, and the impossibility of introducing water or air in large quantities into the intestines, in spite of the unchanged general condition. The urine contained indican. The operation showed a circular carcinoma with a corkscrew canal large enough to pass a knitting needle. All these cases, however, he says, when they have symptoms, are comparatively easy to recognize, but there is a class of neurospastic pseudotumors which occur sometimes in hysteria, or as a pure neurosis, or in connection with other nervous diseases. They may prove very difficult to diagnose, especially when the characteristics of the stools and general condition are similar to that of carcinoma. It is also possible for swelling of the colon to occur in the left iliac fossa with a tumor in another portion of the intestine. He gives illustrative cases. There are, of course, other tumors in this region, such as those originating from the intestine and appendages, from local peritonitis, etc., but he does not discuss these, concluding with remarks on auto-intestinal intoxication as the result of constipation. The symptoms may be acute in onset, very severe in appearance, and accompanied with more or less diminished sensorium of the patient. There may be a paralysis of the extremities, complete absence of the patellar reflexes, involuntary micturition and defecation, with every sign of a severe central brain disease, but differing from it by the bilateral paralysis; from meningitis by absence of the neck rigidity and pupillary symptoms; from disease of the spinal cord by the occasional occurrence of coma. The use of irrigations of lukewarm oil or hot water brings away masses, and, together with lavage of the stomach, the whole picture becomes suddenly changed. He thinks such attacks undoubtedly arise as a result of absorption of toxic agents produced by putrefaction in the intestinal tract. In two cases he has found the aromatic sulphates markedly increased.

66. **Chronic Polyarthritis.**—Edsall and Lavenson have used the tuberculin test in 18 cases of chronic polyarthritis and find positive reactions in 7 cases, with 3 dubious ones. They think that these furnish strong presumptive evidence in favor of Poncet's view that many cases of polyarthritis are of tubercular origin.

67. ***Trifacial Neuralgia.***—*Frazier concludes with the following:*

1. In all incipient cases remove the predisposing cause and administer strychnin *hypodermically* in heroic doses under proper precautions, and with such adjuvants as have been suggested. 2. In cases that do not respond to this mode of treatment, where the pain is referred to but one branch, recommend the peripheral operation, even though the operation may have to be repeated. It will afford relief, at least *temporarily, in every case, and in some cases* permanently. 3. When the peripheral operation has failed to afford but temporary relief, even though it may have been properly executed and repeatedly performed, or when from the onset the pain is referred to two or more branches, recourse should be had at once to an intracranial *operation*: either division *of* the sensory root or, in certain selected cases, division of the second and third divisions, with interposition of a foreign substance to prevent reunion.

70. **Diphtheria Antitoxin.**—Marsh reports a case to show that injection of antitoxin is once in a while followed by alarming symptoms. The patient became almost cyanosed and semicomatose, had subsequently a numb feeling, pain in the epigastric region and vomiting, and immediately thereafter a severe stinging, itching rash came out all over the body. It took about thirty-six hours for this urticaria to disappear. He thinks a large dose would have been fatal in this case. This, he thinks, was due to an idiosyncrasy of the patient to anything coming from a horse, which was notable in her history otherwise. She was always seized with unaccountable sneezing attacks when driving behind a horse.

72. **The Respiratory Symptom in Hemiplegia.**—Clark has examined 161 cases of hemiplegia to make certain the constancy of the respiratory symptoms noted by Jackson. He observed that automatic overaction was greater on the paralyzed side, and that the reverse was the case in volitional respiration, and found that this phenomenon was constant. The difference in the cases is only one of degree. He discusses the explanation of the symptom on the basis of Spencer's work as to the respiratory centers, and emphasizes the necessity for more information in regard to the location of these centers by degeneration experiments.

73. **The Foot of the Negro.**—Freiberg and Schroeder have examined a number of colored persons' feet and find that flattening of the arch of the foot, from the data obtained, is more frequent in the negro than in the white. Hallux valgus is also more frequent, but, nevertheless, well-arched feet appear sufficiently frequently to establish them as normal. In the negro child the normal foot preponderates. They therefore infer that the flat foot of the adult American negro is an acquirement due to the deforming effect of footwear of improper construction.

74. **The Antagonistic Action of Drugs.**—Haskins, at Sollman's suggestion, has studied the question whether a drug which excites a given structure can remove the effects of another drug which depresses it. Alcohol and strychnin were first suggested as the subject of investigation, but were found unsuitable, as alcohol does not produce the effects credited to it, and strychnin does not prevent alcoholic excitement. Haskins therefore studied the effect of the simultaneous action of stimulation and depressants on yeast cultures, using various degrees of heat as a stimulant and contrasting it with the depressing action of strychnin. The results show that the antagonism is not as simple a phenomenon as would be expected if the stimulant action of heat neutralized the depressant action of strychnia. They are more in agreement with the complicated condition which would occur with superimposition of stimulation and depression. It must be granted, however, that stimulation by heat may be of a different nature from stimulation by drugs. There may be various types of physiologic antagonism among drugs. These matters can not be settled until a large number of antagonisms have been studied. The experiments with alcohol were mainly tried *on cats and are given in detail. The conclusions are:*

1. Strychnin does not seem to affect the pulse when given simultaneously with alcohol. 2. In some cases strychnin seems to counteract in part the depressing effect of acute alcoholic poisoning on the respiration, and thus prolong life. The one apparent exception is doubtless explained by the poor physical condition of the cat receiving strychnin, and by the small dose. 3. Strychnin does not seem to interfere materially with the narcosis from acute poisoning with alcohol, but, apparently, does delay the onset of paralytic symptoms. 4. In subacute alcoholic poisoning strychnin seems to lessen the narcosis and paresis in the earliest stages, but in the later stages to increase the depression. However, a general conclusion is hardly justified, since only one control experiment was made. 5. Although in no case was the strychnin competent to completely remove the effects of the large doses of alcohol which were employed, yet it may be considered probable that appropriate doses of strychnin (fairly strong therapeutic doses) would prove useful in the treatment of poisoning from even lethal doses of alcohol. 6. No action on the nerve cells by either alcohol or strychnin was demonstrable histologically. 7. Many drugs depress the activity of yeast cells, but no reliable stimulant was found; therefore, the antagonism of drugs in their action on these cells could not be studied. 8. Heat was found to be a reliable stimulant up to 45 C., but strychnin as an antidote to heat did not give uniform results at the successive temperatures, so that the antagonism is not a simple one.

75. **Blood Changes in Paresis.**—Diefendorf has studied the blood changes occurring in paresis in the 11 cases here reported. He concludes that the disorder is accompanied with moderate progressive anemia, involving especially the hemoglobin, and becoming more marked as the disease progresses. The terminal stage of the disease is accompanied by a rise in the hemoglobin, erythrocytes, and a leucocytosis. Paralytic attacks are accompanied by a leucocytosis. Throughout the disease process there is a pathologic increase of polymorphonuclear leucocytes which reaches its height during the terminal state. States of paretic excitement, stupor or quiescence, not terminal, have no characteristic blood changes. The presence of leucocytosis accompanying the terminal state and paralytic attacks is significant evidence in favor of the toxic origin of the disease.

83 Some Factors in the Spread of Typhoid Fever. Frank H. Russell.
84 *Euphthalmin as a Mydriatic for the General Practitioner. Albert B. Hale.

80. **Hernia of the Ovary.**—The case described by Black was not in its clinical symptoms as serious as the actual conditions showed. The patient was induced to submit to operation only after much urging. The sac was examined and found to contain a small mass which was undoubtedly the ovary, and a considerable cavity associated with it containing pus. Meckel's diverticulum projected into the cavity, and the intestine was in such a bad condition from contact with the pus cavity that several inches of it had to be resected

and united by end-to-end anastomosis with the Murphy button. A still further examination of the cavity revealed the appendix, which was gangrenous and ruptured. The ovarian hernia, Black thinks, was, perhaps, congenital; the presence of the diverticulum was only an incident. The disorganization of the diverticulum and intestinal wall was caused by the contact with the abscess caused by the ruptured appendix.

81. **The Tampon in Postpartum Hemorrhage.**—Bacon concludes that the tampon can be used in postpartum hemorrhages as a carrier of styptics to cause coagulation of blood in cases of inherited or acquired hemophilia, to control postpartum hemorrhage in placenta previa, and also to control the bleeding from cervical lacerations where surgical interference is impossible.

82. **Typhoid Fever.**—Davis has used *acetozone* in 59 cases, giving it in water in the usual doses. Among the 59 there were 2 who died at the very beginning of treatment; excluding them, the percentage of fatalities is 10. Twenty-one patients during the summer months were treated in the same way in every respect, but without the acetozone, and 2 of these who died might be excluded because of death occurring almost immediately after entering the hospital. Without these, the percentage of mortality would be 19. Among those who used acetozone he finds that those admitted to the hospital in the first week of their illness averaged 21.25 days of the fever, ranging from 9 to 33 days. Those admitted in the second week averaged 31.5 days of the fever, ranging from 10 to 83 days; in the third week 7.7 days of fever ranging from 20 to 58 days, and those appearing after the third week averaged 44.5 days of fever, ranging from 32 to 71 days. Among a small number that did not get acetozone those admitted in the first week averaged 28.6 days with a range of from 19 to 42; those in the second week 26 days, ranging from 13 to 39; those in the third week 41.5 days, ranging from 33 to 50, and those appearing after the third week averaged 54 days of fever, and ranged from 28 to 81 days. The number is small, but the statistics emphasize the value of early treatment and show apparently that the use of acetozone apparently shortened the disease. It did not seem to produce visible effects. Twenty grains of the acetozone were dissolved in two quarts of water, and a glass of the solution administered every two or three hours and equal parts of medicated water and milk were in some cases given more frequently. The fluid seems to promote excretion by the kidneys.

84. **Euphthalmin.**—Hale finds that euphthalmin is a powerful and effective drug, and the best pure mydriatic we have for diagnostic purposes.

86. **Gonorrhea.**—Nelken insists on the importance of the prostate in the condition of *chronic* gonorrhea and the value of prostatic massage in the treatment. Other pathologic factors can not be neglected, and, of course, if structural changes in the gland have occurred, or there is complicating disease in the viscera, probably of long-standing, then only the most persevering treatment will succeed. He reports cases to prove his assumption that careful systematic massage of the prostate is of the greatest benefit in many cases of gonorrhea.

9 Pilewort Ointment and Suppository. James Sawyer.

1. **Edema of the Lungs.**—Owen describes the phenomenon and thinks that many cases of so-called heart failure in pneumonia are really due to antecedent commencing edema. A careful examination of the back of the chest in pneumonia is often neglected, and the importance of the condition so frequently found in autopsy is often overlooked. He thinks that when the countenance changes, the complexion becomes pale and dusky, the patient drowsy and apathetic, and the pulse begins to flag, one should not content oneself with the diagnosis of toxemia, or collapse, or cardiac failure, but should thoroughly examine for physical signs. The administration of an expectorant for the purpose of removing edematous fluid is a mistake, as such fluid can not be expelled by coughing. The principal thing is to examine thoroughly the right side of the heart and look for evidences of obstructive venous circulation. If the signs are profound, perform venesection promptly. Failing to do this, leeches, free water purgation, or pilocarpin, may be of value. The continued use of alcohol in this condition is useless and may be harmful. Atropin and ammonia are indicated theoretically. Strychnin has produced marked improvement when given hypodermically, and has become part of his routine treatment.

2. **Postural Albuminuria.**—Broadbent finds as an antecedent in cases of this condition a neurotic family history and cardiovascular instability or brain abscess. He has never seen any serious renal disease result; usually all the treatment required is simple food, fresh air and vigorous exercise. If these cases are treated for renal disease they will probably get worse.

6. **Tubercle Bacillus in the Urine.**—Trevithick has found the following methods eminently successful: The urine is allowed to stand in a conical glass and the lower portion is centrifuged. The supernatant fluid is then carefully decanted off and the centrifuge receiver is filled with distilled water and shaken. This is again centrifugalized and the process repeated. After the final centrifugalization the bacilli found in the films prepared from the sediment will be greatly in excess of those demonstrated in the same urine where this precaution of washing away the urinary salts is not practiced.

8. **The Vas Deferens in Anastomosis.**—Thomas operates by slitting up the urethral end of the severed vessel, a little higher on one side than on the other; thus forming two tails of equal size. The obliquely cut free end of the testicular portion of the vas was placed with its lumen in contact with that of the testicular portion and fixed by means of fine silk suture as closely applied as possible. The two tails of the distal end were then enveloped around the testicular portion in order to counteract the disruptive forces of the weight of the testicle. Afterward the layers of the fascia were wrapped around the anastomosed vas deferens and fixed by sutures. The invagination of the ends is impossible in this case on account of the smallness of the tube. The use of this method makes union more certain.

24 Some Observations Regarding the Special Circumstances of Cases of Lead Poisoning Occurring Among Workers in White Lead Factories. Theodore A. W. Ogg.

10. **Diphtheria.**—Caiger discusses the difficulties of determining diphtheria by clinical appearances and also pseudodiphtheria germs which may confuse the diagnosis. The ordinary bacteriologic test, therefore, is not absolutely reliable in all cases, but where the symptoms or anomalies are abundant it is valuable. In suspected cases he would isolate the patient, disinfect everything, examine the throat, nasal passages and all tissues, isolate or exclude all contact with persons with doubtful diphtheria bacilli in their throats, and search for every possible source of infection, doing everything that may possibly serve to lessen the infectivity of the patient and shorten the term of detention. The average period of diphtheria bacilli persisting in the throat was about twenty days. He thinks it may be longer in hospital wards. Sometimes they may be detected three months after the attack. The longest time on record, he says, was not quite a year. Adenoids seem often to be responsible for undue persistence of the germs, and great care should be exercised in assuring oneself that the germs are not present before operation is performed. Antitoxin should always be given without exception, and in case of infected contact with any signs of faucial, laryngeal or nasal inflammation.

12. **Smallpox.**—Neech and Hodgson have used local treatment with carbolic acid in 136 cases, with 5 deaths. Many of the cases were severe, 22 were confluent, 12 were semi-confluent, and some of the discrete cases were of the severer type. The symptoms were decidedly modified, the fever and odor diminished, and delirium was infrequent. The risk of aerial convection was, they think, very much decreased. There was an entire absence of complications, such as multiple abscess, etc.

13. **Yellow Fever.**—Tombleson refers to his former article, abstracted in THE JOURNAL of September 19, ¶12, p. 752. He gives a tabulated analysis of 25 cases and a record of finding of the bacillus, which he has described, in infected mosquitoes and their larvæ. He also fed mosquitoes on the blood of yellow fever cases, and found the bacilli in every stage of growth and sporification in them. He stained with carbotoluidin blue, prepared by adding to a 5 per cent. solution of carbolic acid enough saturated solution of toluidin blue in absolute alcohol to make the mixture a deep blue color. He stained with this for three hours and dried by heat, without any dehydration with alcohol, cleared it up with xylol, and mounted. This was, of course, in section preparations. In the blood slides no dehydration was required. One point in the treatment of yellow fever is mentioned. He uses large injections of warm water into the large bowel from the beginning of the third day of the disease to the end, two quarts twice daily, taking half an hour or more to the operation, and finds this method always beneficial in preventing secondary fever.

14. **Appendicitis.**—Bennett calls attention to deceptive symptoms, for example, in advancing sepsis and intoxication where the gangrenous appendix produces anesthesia with apparent improvement. This is particularly the case in young growing children even when the infective processes are very acute and the results destructive. The changes are followed so rapidly by necrosis and decomposition that the commencement of septic intoxication is begun before the patient realizes the

onset of the condition. In fact, before the ordinary symptoms develop the patient has become dull and listless from the rapid absorption of septic material. He refers to the stomachaches of boys as deserving of more attention than they receive, since they are sometimes the indication of appendiceal trouble. There is one sign that is almost pathognomonic of appendiceal involvement, that is, a feeling of discomfort about the right iliac region on stretching of the lower limbs, a condition which never follows mere stomachache. But no one sign can be relied on alone.

17. **Ochronosis.**—Osler reports two cases in alkaptonuria in which the condition was clinically recognizable by deep pigmentation of the cartilaginous tissue and sclerotics. In one it resembled an ebony-black discoloration of the skin, nose and cheeks. The relation of this discoloration to metabolic changes shown by the urine is especially noted, but all cases of ochronosis are not to be found in alkaptonuria.
